more than one layer high, with a little room between slices
for air circulation. Use only part of a commercial dehydr-
ator so that it isn't overloaded with moisture. Gen MacMani-
man says to dry them at 110°F (it takes up to 30 hours).
Some people who dry tomatoes dehydrate them at up to
140°F in a homemade dehydrator or at 120–200°F in an
oven—with either dehydrator or oven door propped open
several inches. If using the higher temperatures, check
every 15 to 30 minutes because tomatoes scorch easily in
the last stage. With care they can dry very nicely, keeping
their flavor and color. Dry until shriveled and slightly flexi-
ble yet not brittle. To make tomato leather, use the basic di-
rections for making food leathers in Chapter 7.

**Tomato Paste.** Start with a paste-type tomato variety. Cook
to softness, blend or process into a puree, and simmer until
reduced in volume by 50 percent. (Stir often and don't let it
scorch!) Now can in pint jars in a pressure canner using the
times and directions for canning pumpkin (see "Winter
Squashes"). Or spread a 1/2-inch layer of the thick puree
onto a cookie sheet. Dry in dehydrator or sun until no
longer sticky (maybe 2 days). Then make into balls, dip in
oil, and store in a tightly lidded jar in a very cool place. Op-
tional: Add basil, parsley, oregano . . .

**Dried Tomato Recipe Ideas.** Season with salt, basil, and
oregano and marinate in olive oil in a dark place for at least
4 weeks. Or add to soup, stew, chili, or lasagna. Or pour
boiling water over, simmer until tender, season as you
would stewed tomatoes, and serve. Or grind to a powder
and add that to meat loaf, casseroles, etc.

**Canning:** I can tomato juice, sauce, and stewed toma-
bies while they are in season. Literally bushels of tomatoes
are picked in the process for canning any other kind of food:

- **Frozen Green Tomatoes.** Can also be used as an alterna-
tive to water-bath canning.
- **Crushed Tomatoes.** Can and either bottle or can.
- **To pack them hot without any added
warmth over, simmer until tender, season as you
- **Season with salt, basil, and
- **Crushed Tomatoes.** To pack them hot without any added
liquid, cut your prepared tomatoes into quarters. Heat them

**Big Changes in Tomato Canning:** Recent research
has caused more changes in the tomato-canning process than
in the process for canning any other kind of food:

1. Because tomatoes are the least acidic of all the foods
defined as "high-acid," and because acidity varies so
much, canners are now urged to always add citric acid
or lemon juice to all water-bath-canned tomatoes in
order to raise their acidity. Water-bath canning is okay
for plain tomatoes, but they must be acidified.
2. Processing times have been lengthened.
3. Pressure canning can be used as an alternative to wa-
ter-bath canning.
4. Recommended pressures now differ for dial and
weighted-gauge canners. (This is true of canning any-
thing!)
5. Altitude adjustments for both boiling-water canners
and pressure canners have been revised. (This is also
true for all canning recipes.)

**Adding Acid, Sugar, and Salt to Canned Tomatoes.** Add
1 T. bottled lemon juice per pint or 2 T. per quart. Or add
1/4 tsp. USP citric acid per pint, 1/2 t. per quart. Some people
add a little sugar to mask any sour flavor: 1 t. sugar per
pint, 2 t. per quart. You can add salt to taste; it doesn't help
preserve the tomatoes. On average, people add 1/2 t. salt per
pint, 1 t. per quart.

**Choosing and Preparing the Tomatoes.** The amount of
tomatoes it takes to make a canned quart ranges from as
little as 2 1/2 lb. for crushed tomatoes to 3/4 lb. for tomato
juice, on up to 5–6 1/2 lb. for tomato sauce. Select firm, un-
derripe-to-ripe tomatoes. Never use decayed or overripe
ones because their presence can significantly lower the acidi-
ity. Don't can tomatoes from dead or frost-killed vines.
Wash tomatoes in cool running water. Skinning is optional.
To skin, dip into boiling water for 30 to 60 seconds or until
skins split. Dip in cold water; slip off skins.

**Crushed Tomatoes.** To pack them hot without any added
liquid, cut your prepared tomatoes into quarters. Heat them

356
**Whole/Halved Tomatoes Packed in Water.** Prepare as above, but leave whole or cut in halves. To raw-pack, fill jars with raw, peeled tomatoes. Cover with hot water, leaving \( \frac{1}{2} \) inch headspace. To hot-pack, add enough water to cover tomatoes in a large pan. Boil gently for 5 minutes. Fill jars with hot tomatoes. Cover with hot cooking liquid, leaving \( \frac{1}{2} \) inch headspace. Add acid to both hot- and raw-packed tomatoes. Adjust lids and process in a boiling-water bath. For quarts: At up to 1,000 feet above sea level, process 45 minutes; at 1,001–3,000 feet, 50 minutes; 3,001–6,000 feet, 55 minutes; and above 6,000 feet, 60 minutes. Process pints for 10 minutes less than the time given for your altitude.

To use a pressure canner, process for 15 minutes. If using a weighted-gauge canner, set at 10 lb. pressure at 0–1,000 feet above sea level; set at 15 lb. at higher altitudes. If using a dial-gauge canner, set at 11 lb. pressure at 0–2,000 feet above sea level; 12 lb. at 2,001–4,000 feet; 13 lb. at 4,001–6,000 feet; 14 lb. at 6,001–8,000 feet; or 15 lb. above 8,000 feet.

**Whole/Halved Tomatoes Packed in Tomato Juice.** Prepare as above, but leave whole or cut in halves. To raw-pack, fill jars with raw, peeled tomatoes. Cover with hot tomato juice. Leave \( \frac{1}{2} \) inch headspace. To hot-pack, add enough tomato juice to cover tomatoes in a large pan. Boil gently for 5 minutes. Fill jars with hot tomatoes. Cover with hot cooking liquid, leaving \( \frac{1}{2} \) inch headspace. Add acid to both hot- and raw-packed tomatoes. Adjust lids and process in a boiling-water bath. For quarts: At up to 1,000 feet above sea level, process 45 minutes; at 1,001–3,000 feet, 50 minutes; 3,001–6,000 feet, 55 minutes; and above 6,000 feet, 60 minutes. Process pints for 5 minutes less than the time given for your altitude. Process pints or quarts in a pressure canner for 15 minutes at the correct pressure for your altitude, as indicated in the preceding Crushed Tomatoes recipe.

**Whole/Halved Tomatoes Packed in Tomato Juice.** Prepare as in the preceding recipe and tomato juice as in the following Canned Tomato Juice recipe. To raw-pack, heat the tomato juice in a pan. Fill jars with raw tomatoes. Cover with hot tomato juice. Leave \( \frac{1}{2} \) inch headspace. To hot-pack, completely cover tomatoes with tomato juice in large pan. Boil gently for 5 minutes. Fill jars with hot tomatoes and cover with hot tomato juice, leaving \( \frac{1}{2} \) inch headspace. Add acid to jars of either hot- or raw-packed tomatoes. Adjust lids. Process pints or quarts in a pressure canner for 25 minutes at the correct pressure for your altitude, as indicated in the Crushed Tomatoes recipe. To process pints or quarts using a boiling-water bath: At up to 1,000 feet above sea level, process 85 minutes; at 1,001–3,000 feet, 90 minutes; 3,001–6,000 feet, 95 minutes; and above 6,000 feet, 100 minutes.

**Whole/Halved Tomatoes Packed Raw Without Added Liquid.** Prepare tomatoes as above. Leave whole or halved. Loosely fill jars with raw tomatoes, pressing until spaces fill with juice. Leave \( \frac{1}{2} \) inch headspace. Add acid. Adjust lids and pressure-can pints or quarts for 25 minutes at the correct pressure for your altitude, as indicated in the Crushed Tomatoes recipe. Or process pints or quarts using a boiling-water bath for the times indicated in the Whole/Halved Tomatoes Packed in Tomato Juice recipe.

**Canned Tomato Juice.** Wash, remove stems, and trim off bruised or discolored portions. Slice or quarter tomatoes into a large pan. Crush, heat, and simmer for 5 minutes before juicing. Press the heated, crushed tomatoes through a sieve or food mill to remove skins and seeds. Heat juice again to boiling. (If you made the juice in a blender or Squeezo strainer, cook it 5 minutes more to get out the bubbles so they don’t pop off the jar lid.) Fill jars with hot juice, leaving \( \frac{1}{2} \) inch headspace. Add acid—especially if you used overripe tomatoes. Adjust lids and process pints or quarts in a pressure canner for 15 minutes at the correct pressure for your altitude, as indicated in the Crushed Tomatoes recipe. Or process in a boiling-water bath. For quarts: At up to 1,000 feet above sea level, process 40 minutes; at 1,001–3,000 feet, 45 minutes; 3,001–6,000 feet, 50 minutes; and above 6,000 feet, 55 minutes. Process pints for 5 minutes less than the time given for your altitude.

**Canned Tomato Sauce.** Prepare tomatoes, heat, and simmer tomatoes as for making tomato juice. An average of 22 lb. of tomatoes is needed per 7-qt. canner load. Add no more than 3 c. of any combination of finely chopped celery, onions, carrots, and peppers to each 22 lb. of tomatoes. Simmer mixture 20 minutes. Press hot, cooked tomatoes and vegetables through a sieve or food mill to remove skins and seeds. Reheat tomato-vegetable juice blend to boiling and fill jars immediately, leaving \( \frac{1}{2} \) inch headspace. Add acid. Adjust lids. Process pints or quarts in a pressure canner for 15 minutes at the correct pressure for your altitude, as indicated in the Crushed Tomatoes recipe.

**Spaghetti Sauce Without Meat.**

**NOTE:** It is not safe to increase the proportion of onions, peppers, celery, or mushrooms in this recipe if you are planning to can the sauce.

Wash 30 lb. tomatoes and dip in boiling water for 30 to 60 seconds or until skins split. Dip in cold water and slip off skins. Remove cores and quarter tomatoes. Boil 20 minutes, uncovered, in large pan. Put through food mill or sieve. Sauté in \( \frac{1}{4} \) c. vegetable oil until tender: 1 c. chopped onions, 5 minced garlic cloves, 1 c. celery or green pepper (chopped), and (optional) 1 lb. sliced mushrooms. Combine sauteed vegetables and tomatoes. Add 2 T. salt (or to taste), 2 t. black pepper, 2 T. oregano, \( \frac{1}{4} \) c. minced parsley.

---

**NOTE FOR RECIPES**

- 1 lb. mushrooms = 2½ c. sliced mushrooms
- 1 lb. onions = 2½ c. chopped onions
- 1 lb. peppers = 10 large peppers
- 1 lb. tomatoes = 3–4 small tomatoes
and ¼ c. brown sugar. Bring to a boil. Simmer, uncovered, until thick enough for serving. (The volume should be reduced by nearly half.) Stir frequently to avoid burning.

Fill jars, leaving 1 inch headspace. Adjust lids. Process in a pressure canner 20 minutes for pints, 25 minutes for quarts. If using a weighted-gauge canner, set at 10 lb. pressure at 0–1,000 feet above sea level; set at 15 lb. at higher altitudes. If using a dial-gauge canner, set at 11 lb. pressure at 0–2,000 feet above sea level; 12 lb. at 2,001–4,000 feet; 13 lb. at 4,001–6,000 feet; 14 lb. at 6,001–8,000 feet; or 15 lb. above 8,000 feet.

Spaghetti Sauce with Meat. Prepare 30 lb. tomatoes as in preceding Spaghetti Sauce Without Meat recipe. Sauté 2½ lb. ground beef or sausage until brown. Drain off fat. Add 5 minced garlic cloves, 1 c. chopped onion, 1 c. chopped celery or green peppers, and 1 lb. sliced mushrooms (optional). Cook until vegetables are tender. Combine vegetables with tomato pulp in a large pan. Add 2 T. salt (or to taste), 2 t. black pepper, 2 T. oregano, ¼ c. minced parsley, and ¼ c. brown sugar. Bring to a boil. Simmer uncovered until thick enough for serving (till volume is reduced by nearly half). Stir frequently to avoid burning. Fill jars, leaving 1 inch headspace. Adjust lids and process in a pressure canner 60 minutes for pints, 70 minutes for quarts. If using a weighted-gauge canner, set at 10 lb. pressure at 0–1,000 feet above sea level; set at 15 lb. at higher altitudes. If using a dial-gauge canner, set at 11 lb. pressure at 0–2,000 feet above sea level; 12 lb. at 2,001–4,000 feet; 13 lb. at 4,001–6,000 feet; 14 lb. at 6,001–8,000 feet; or 15 lb. above 8,000 feet.

Stewed Tomatoes. You'll need 1 gal. peeled, cored, chopped tomatoes, 1 c. chopped onion, ¼ c. chopped green pepper, and 2 t. salt. Combine those in a pan, cover, and cook over gentle heat for about 10 minutes. Then ladle hot mix into hot jars. Allow ½ inch headspace. Put lids on and tighten. Process in pressure canner: pints 15 minutes, quarts 20 minutes. If using a weighted-gauge canner, set at 10 lb. pressure at 0–1,000 feet above sea level; set at 15 lb. at higher altitudes. If using a dial-gauge canner, set at 11 lb. pressure at 0–2,000 feet above sea level; 12 lb. at 2,001–4,000 feet; 13 lb. at 4,001–6,000 feet; 14 lb. at 6,001–8,000 feet; or 15 lb. above 8,000 feet.

Basic Garden Vegetable Soup for Canning. Prepare 1 gal. peeled, chopped tomatoes 3 qt. peeled, chunked potatoes, 2 qt. snapped green beans, 2 qt. corn cut off the cob (about 20 ears), 3 qt. carrot chunks (about ½-inch), 1 qt. onion chunks, 8 crushed garlic cloves, 1 T. black pepper, and salt and other spices according to your taste and preference. Combine vegetables in a big pan; add 3 qt. water. Bring to a boil and cook 5 minutes. Dip hot into clean pint or quart jars. Leave 1 inch headspace. Put on lids. Process in pressure canner only for 95 minutes for pints or quarts. If using a weighted-gauge canner, set at 10 lb. pressure at 0–1,000 feet above sea level; set at 15 lb. at higher altitudes. If using a dial-gauge canner, set at 11 lb. pressure at 0–2,000 feet above sea level; 12 lb. at 2,001–4,000 feet; 13 lb. at 4,001–6,000 feet; 14 lb. at 6,001–8,000 feet; or 15 lb. above 8,000 feet.

RAW TOMATO RECIPE IDEAS: Our summer tomatoes are usually eaten fresh, mouthful by mouthful, juice running down grinning, happy chins. For meals, I serve the tomato cut in thick slices, skin and all. But if you dip the tomato in boiling water for 1 minute and then into cold water, you can easily slip off the skin. We also like tomatoes in sandwiches and salads.

Making Tomato Flowerets for Salads. Choose small tomatoes of equal size. Cut across 3 or 4 times not quite to the base. The tomato should open up like a water lily. You can put a little blob of mayonnaise in the center with a pinch of chopped parsley on top.

Tomato Juice Recipe Ideas: Tomato juice can be drunk plain from fresh, canned, or frozen sources. Or to 2½ c. tomato juice, add a trace of pepper, a pinch of salt, 1 T. lemon juice, ½ t. horseradish, and a pinch of celery salt. Or combine 1 part each celery juice and tomato juice, and season to taste. Or combine 1 part each grapefruit juice and tomato juice; then add a squeeze of lemon juice and a dash of salt. Or combine 1 part each sauerkraut juice and tomato juice; then add a squeeze of lemon juice, and spice it up with Tabasco and Worcestershire if you have an iron stomach.

Gazpacho From Ruth of Bonaire: Combine in blender 4 c. tomato juice, 2 tomatoes, juice of ½ lemon, 1 peeled cucumber, 2 green onions, 1 celery stalk, 1 T. tamari, and basil, oregano, and/or parsley. Serve well-chilled.

RAW-TOMATO SPAGHETTI SAUCE Make the sauce at least 1½ hours before you’re going to serve it. After you have your sauce all made and it has rested 1½ hours to get the flavors well-blended, add your cooked spaghetti (well-drained), mix it up with the sauce, and serve right away. To make the sauce: Combine ½ c. olive oil, about a dozen medium-sized fresh tomatoes (sliced very thin), 20 leaves of fresh basil (torn across), 3 mashed garlic cloves, 1 t. salt, and a pinch or two of freshly ground pepper.

Cooked Tomato Recipe Ideas: Briefly sauté chopped tomatoes and stir into a pasta dish together with melted cheese. Or add to any vegetable and/or meat soup. Or sauté with onion and cooked chicken strips; then toss with cooked noodles. Or sauté chopped tomatoes with garlic, basil, chopped sweet peppers, and onions; simmer a bit and serve as a sauce over pasta or bread.

Italian gravy Fry 1 medium chopped onion, 1 chopped garlic clove, and 2 T. chopped parsley in 4 T. olive oil until light brown. Add ½ lb. ground beef, ½ t. salt, and a pinch of pepper, and cook until the meat loses its redness. Blend in 1 can tomato paste and 1 small can of tomatoes or puree. Simmer for 1 to 1½ hours (longer tastes better), stirring occasionally. Add chicken, sausage, meatballs, pork chops, steak, or wiener to the gravy while simmering.

Stewed Tomatoes Slice and peel into a cooking pan. Cook for 5 minutes and season with salt and pepper. Serve plain or on slices or cubes of toasted homemade bread.

Instant Ketchup Put 3 t. cornstarch in pan over medium heat and make a paste by gradually adding 2 c. tomato juice. Flavor with ½ t. salt, 1 t. honey, a little onion, and garlic salt. Optional: Add a pinch of red pepper.

Seventh edition. Four days ago I had a baby, my sixth! On Monday I wrote the new version of the pepper section, which is mostly like writing from scratch because I've been expanding it so much. Tuesday morning I woke up and my water broke (in exactly that sequence—I was still lying in bed). My labor didn't start, but after a while Mike took me
to the hospital anyway, because once before, with Rebecca, I had had the baby about 3 hours after the water had broken, which is fast as these things go. Even though Mike has tested a cow for pregnancy and delivered umpteen farm-animal babies, he doesn't want to get stuck delivering one of ours.

So he took me to the hospital labor room. I lay there all day wishing I could get to work on the potato section of this book. I felt very bored and sort of guilty because Mike had work to do too, and there we were and nothing was happening. Then at 5pm I had a contraction, at 5:15 another, at 5:20 another, and at 5:25 another. The nurse came in and I told her that I thought something might be happening. She said I'd have to be more regular than that, and then she left. Then everything stopped for 30 minutes. Then I had contractions for another half hour, then nothing for the next half hour. From 7 to 8pm the labor ambled along in a semiserious way. The nurse checked me and said I was 3 centimeters dilated. (I had been 2 cm that morning, when I had checked in.)

At this point, I asked her to call my doctor, Dr. Drury. He had repeatedly made me promise that I'd let him know when “labor started” because, he said, “I have a feeling it might go pretty fast once you get started.”

The nurse thought the call was premature. “It's too early,” she said. But I humbly requested again, and she made the call.

In the meantime, nothing happened: still no serious contractions, still no good dilation. At 8:30 Mike was seriously considering going for a walk. But then I had some harder contractions, and he decided to stick around. At 8:45 I asked him to please tell the nurse it was feeling more serious. She came in and checked me and said, sounding kind of disgusted by the nuisance of having to measure somebody who wasn't doing much, that I was dilated 5 centimeters. That was at 8:48.

Just as her shoulders were disappearing out the door, I said, “Mike, you better tell her I feel like I'm getting ready to bear down!”

Mike took me absolutely seriously. He jumped up and dashed out into the hall after the nurse. The two of them came racing back with a cart, got me loaded onto it almost as fast as I could say it, and wheeled me into the delivery room, which was directly across the hall. They moved me off the cart and onto the delivery table, getting me in place before that predicted next contraction hit me at about 8:55.

For as soon as I was on the delivery table, here it came. I was bearing down all right! That one contraction moved the baby out of the womb and well down the birth canal. The nurse was running around getting things ready and paging Dr. Drury over the intercom system in case he had already arrived at the hospital, telling him to come to the delivery room immediately. In the meantime she was also yelling at me, “Don't push! Don't push!”

But a few minutes later, I had another powerful bearing-down contraction. I pushed for all I was worth because that was what was happening. Just then Dr. Drury came in the door at a dead run. He threw his coat off onto the floor as he passed through it—just as the baby crowned, because the second bearing-down contraction had moved its head all the way to the opening of the vagina. The others could see the top “crown” and almost to the baby's shoulders—out far enough so that Mike could see that it was as blue as blue ink. It was asphyxiating!

“Push! Push!” screamed the nurse.

I tried to push. With a bit of effort came a third, huge, involuntary bearing-down contraction. It brought the baby out all the way. As it came out, Mike, the nurse, and Dr. Drury could all see why it was blue. The baby had a loop of umbilical cord tightly wound around its neck and another around its chest. But Dr. Drury had the expertise that comes from having helped with hundreds of births. He expertly caught the baby as it slipped out, and in an instant, fluid motion as fast as the wink of an eye, he slipped his fingers under that loop of cord around the baby's neck, gently loosened it, and lifted it over the baby's head. Then he did the same for the other loop around its chest.

The baby gasped its first breath, coughed, cried, and turned a healthy pink!

I was sitting up, sobbing with joy and trying to see every part of the baby at once, trying to comprehend that the baby I had carried unseen for so many months really was, in every part and way, a fine healthy boy. And he was! It makes you believe in miracles.

Today is Saturday, 4 days later. I got home from the hospital on Thursday.

January 12, 1992. That baby—Jacob—is 15 now, almost 16. His brains are fine. He's graduating from high school in a few more months (yes, he's been accelerated 2 years), and he's eagerly awaiting the results of his applications to various colleges. It could so easily have been different. I still ponder that mysterious birth of his, so unlike those of my other children. Jacob was delivered in just 3 huge bearing-down contractions. The delivery time was 9pm on February 15, 1977—exactly 12 minutes after the moment the nurse had said I was merely 5 centimeters dilated. Jacob spent only about 5 minutes in his transit down the passage between the womb and the outside world. That's as long as you can hold your breath without brain damage.

Because of the cord around his neck and chest, if I had delivered that baby any more slowly, he surely would have been born permanently brain-damaged from lack of oxygen—or dead. He was fine as long as he was in the womb, but the moment the womb opened and he entered the birth canal, that cord tightened around his neck and chest; he then ceased to receive oxygen and began strangulation. The unique way that particular birth happened couldn't have been an accident. How did my body know exactly what had to be accomplished? Is there more capacity for communication with and inner direction of one's physiology than we consciously or scientifically understand? I'm so glad I didn't have any anesthetic in my system to mess up that subtle capacity for inner-directed birthing, if such was the case . . .

HERBS

YOUR HERB GARDEN: Unlike spices, herbs can be used fresh from the garden because we temperate-zone dwellers can grow them ourselves. You can plant herbs in a border around your vegetable garden or give them a plot of their own. Kitchen herbs fit nicely into about a 3 x 5-foot area, ideally outside near your back, or kitchen, door! Herbs are grown in solid patches jammed up against each other rather than in rows like a vegetable garden, so you get lots for your space. Some herbs are enthusiastic self-spreading, but wood, stone, or metal edging keeps them within your chosen bounds and can also serve as little footpaths of stones or slate. Some herbs you can start from seed, but many are propagated by division or layering. Some are temperate-zone perennials, but many do best if you bring them in for the winter. Some do fine in an ongoing window box or container setting. For herbs in the house, a southern-facing window in a coolish room is ideal.

INTRODUCTION

An herb lady once told me, “I used to think anybody who grew flowers in their garden was wasting space. Now I don’t grow food any more—just herbs, mostly the herbs I use in my work. Herbs are ornamental, fragrant, and a pleasure to use.” So herbs can be a necessity of life, depending on your convictions. For sure they’re a pleasant luxury, a comfort so natural to country living that I’m including them in this book.

“Herbs” are the leaves or other parts of aromatic plants grown in the temperate zone. “Spices” are the stems, leaves, roots, seeds, flowers, buds, or bark of aromatic plants grown in the tropics. Here are some of the possible directions for your collection:

- Culinary herbs: basil, bay leaf, caraway, chives, mint, parsley, rosemary, sage, tarragon
- Stronger seasoning herbs: capers, dandelion, garlic, horseradish, hot pepper, mustard, nasturtium
- Decorative herbs: bergamot, lovage, rose, rosemary, tansy
- Scented herbs: chamomile, scented geranium, lavender, marigold, mint, patchouli, rose, rue, thyme
- Medicinal herbs: anise, horehound, hyssop, feverfew
- Herbs that are natural pesticides: pennyroyal, pyrethrum
- Herbs that thrive in containers: garlic, parsley, thyme, tarragon, marjoram, oregano, chives, mint, winter savory, geranium, bay leaf
- Edible flowers: marigold, lemon mint, borage, nasturtium, bean, chrysanthemum, cucumber, rose, squash, violet

You can also grow herbs for dyeing, making cosmetics, or attracting bees that make exotic flavors of honey.

Some people doctor with herbs, but not all herbs are as safe or effective as you might think. If you wish you knew what has been scientifically verified about healing herbs, what’s hocus, and what’s dangerous, read The New Honest Herbal (especially the “Remedies” section by Dr. Varro E. Tyler, a plant drug specialist at Purdue University).

Healthwise, I recommend a Seventh-Day Adventist doctor as providing the best of both worlds. On one visit to my Adventist doctor, Dr. Drury, when I was full of mysterious problems, he first wrote me a couple of prescriptions, then gave me some marital advice, and finally prayed for me. Now that’s doctoring! The gist of his advice was that I should quit trying to write this book. He has continued to offer that same advice at every visit. I almost always throw away his paper prescriptions (I just want to hear what he thinks, not get pills) and, as you see, I didn’t obey his advice about the book, so any health problems I end up with are no fault of his! Fact is, though, I feel great.

Dr. Drury was, I think, the last of the old-time country doctors. If you wanted to give birth in his office examining room with only him and his wife (a nurse) to help, he’d let you. Then he’d move you and baby to a waiting room. Some of his waiting rooms had real beds, so sick people or women who just given birth could be genuinely comfortable. My daughter Esther was born that way about 2:30am (she was my seventh). After Dr. Drury got her and me all fixed up, he and his wife went back to their home, just a little way up the road. We stayed there for a while, my husband Mike sleeping on one bed in the room, precious baby Esther and me on the other. Mike woke up at about 6:00am and said, “Well, are you ready to go home?” I answered, “Yes.” We took our new baby, let ourselves out the back door of the silent building, got in our pickup (which was parked out back), and drove home. We loved it—no hospital bill, no hassle! And the expertise of a doctor who had delivered hundreds of babies available if needed.

Dr. Drury had delivered most of the local babies for thirty-some years when the insurance company forced him to quit. Doc explained that they’d made a new rule: the more babies a doctor had delivered (so the more experience he had and the more women trusted him, went to him for theirirthings, and told other women about him), the higher his insurance rates soared. Dr. Drury had delivered so many babies that his rates became absolutely unaffordable. He had to start telling women to go to a young city doc who had only delivered a few and thus could afford insurance.

PUBLIC HERB GARDENS

Brookllyn Botanic Garden offers herbs in their store, books on herbs and growing them, and videos (“Dyeing with Plants,” 10 minutes); classes on herbs; and more: 718-623-4241; 1000 Washington, Brooklyn, NY 11225; www.bbg.org.

Lady Catherine’s Herb & Wildflower Garden features medicinal and period gardens (Biblical, Shakespearean, etc.): 903-639-2254; 1487 County Rd. 2924, Hughes Springs, TX 75656.

Medicinal Herb Garden, founded in 1911, is run by the U. of Washington’s Botany Department (Box 355325, Seattle, WA 98195). It’s on the main campus, open to the public seven days a week, and admission is free. For $25/yr, you get their quarterly newsletter.

The National Herb Garden of the U.S. National Arboretum is the largest herb garden in the world. Founded by the Herb Society of America, it regularly offers...

Our Grandmother's Garden welcomes visitors to their greenhouses and gardens, which display culinary, decorative, aromatic, and medicinal herbs. These include a scented geranium garden and a 17th-century Elizabethan knot garden. Shop offers 450 varieties of herbs: 203-888-5649; 67 Christian St., Oxford, CT 06478.

Ozark Folk Center State Park offers herb vacations at the Ozark Folk Center's Lodge. Its Heritage Herb Garden does a yearly Spring Extravaganza with lavish herbal feast and various seminars: 800-264-3655; Box 500, Mountain View, AR 72560; ozarkfolckcenter@arkansas.com.

Well-Sweep Herb Farm, an old-time family outfit, has one of the largest collections of herbs and perennials in the U.S. They have more than 5 acres of display gardens, featuring common and unusual herbs, scented geraniums, and flowering perennials. They offer special events, courses, and lectures throughout the year. Free catalog. Contact: 908-852-5390; fax 908-852-1649; 205 Mt. Bethel Rd., Port Murray NJ 07865; herbs@goes.com; www.wellsweep.com.

INFO AND NETWORKING: Online, try www.herbworld.com, www.herbnet.com, and www.herbsoociety.org. The latter is a great site maintained by The Herb Society of America: 440-256-0514; fax 440-256-0541; 9019 Kirtland Chardon Rd., Kirtland, OH 44094; herbs@herbsociety.org. You can e-mail herbworld@aol.com with herb-related questions.

The Herb Growing and Marketing Network publishes The Business of Herbs: International News and Resource Service for Herb Businesses 6 times/yr: www.herb-biz.com/bofh.htm. It also publishes (The) Herbal Connection, a bimonthly that provides info on growing and using herbs. Their $20/yr membership fee gets you a newsletter, their industry herb directory, The Herbal Green Pages, listing hundreds of small growers with herbs to sell, and a cooperative herb buying program: www.herbworld.com; 717-393-3295; PO Box 245, Silver Spring, PA 17575-0245; herbworld@aol.com; www.herbnet.com. They're an "herb world" indeed!

Rodale's Illustrated Encyclopedia of Herbs (1987) is a print overview of kitchen and medical herbs. Herbs: Partners in Life, by Adele G. Dawson, is a guide to cooking, gardening, and healing with 70 wild and cultivated plants, written by a 76-year-old Vermont herbalist (available from Southern Exposure Seed Exchange). The Harrowsmith Illustrated Book of Herbs, by Patrick Lima, is helpful for northern gardeners. Storey Books offers many herb books, such as The Art and Skill of Teaching about Herbs, a teaching packet by Portia Meares.

OTHER HERB PERIODICALS
(1999) is a sophisticated, fascinating quarterly collection of articles on the medicinal uses of herbs and other topics of interest to serious and well-educated students of materia medica. They sell a goldenseal data base of 25,000 goldenseal plants. The magazine costs $25/yr: 512-928-4900; 800-373-7105; American Botanical Council, PO Box 144345, Austin, TX 78714-4345.

The Business of Herbs

BUYING HERBS AND HERB PRODUCTS: Herb growing and use are enjoying renewed popularity both with builders of beautiful cuisines and fragrant potpourris, and with seekers after kinder, gentler, cheaper cures for what ails them.

Here's a list of places to buy herbs. Later in this chapter, as I discuss specific herbs, I'll note the firms that sell them. If you don't find their addresses below, look in the introduction to Chapter 2 (for firms that also carry vegetables) or the source list in Chapter 6 (for those that specialize in trees and fruits).

HERB PRODUCTS

Indiana Botanic Gardens sells by mail-order dried herbs, essential oils, floral scents, potpourri, spices, etc. Free catalog: orders 800-644-8327; info 800-514-1068 or 219-947-4040; fax 219-947-4148; PO Box 5, Hammond, IN 46325; www.botanichealt.com.

LorAnn Oils sells essential oils, flavorings, and specialty ingredients for soap-, candle-, and food-crafters: 4518 Aurelius Rd., Lansing, MI 48910; 800-862-8620; 517-882-0215; fax 517-882-0507; customercare@lorannois.com; www.lorannois.com.

Penzey's Spices offers 250+ spices and spice blends for gourmet cooks including arrowroot, vanilla beans, ajwain seed, annatto seeds, cassia buds, and gumbo file: 262-785-7676; 800-741-7787; PO Box 924, Brookfield, WI 53008-0924; www.Penzey's.com.

HERB PLANT SOURCES: Herbs are sought after by cooks, decorators, and healers. For hard-to-find sources of seeds and growing info, order the 96-pg encyclopedia Ethnobotanical Catalog of Seeds. It's $1 from J. L. Hudson.
Abundant Life Seed Foundation sells herb seeds and books, etc. Catalog, $2: 360-385-5660; PO Box 772, Port Townsend, WA 98368; www.abundantlifeseed.org.

Burnt Ridge Nursery specializes in unusual trees, shrubs, and vines that grow edible nuts or fruit: 360-985-2873; 432 Burnt Ridge Rd., Onalaska, WA 98570; burntridge.myhome.net; landru.myhome.net/burntridge.

Cricket Hill Herb Farm, Ltd.: 978-948-2818; 74 Glen St., Rowley, MA 01969.

Dabney Herbs sells herbs, native Midwestern plants, books, etc.: 502-893-5198; Box 22061, Louisville, KY 40252; dabnyherb@win.net; www.dabneyherbs.com.

Garden Medicinals and Culinary offers 170 varieties of herb seeds, roots, tubers, and specialty garlics, herb books, and supplies/equipment for herb growers and herbalists. Many links to herb-related and phytotherapeutic sites from their website: www.gardenmedicinals.com. Catalog, $2: 434-964-9113; fax 434-973-8717; PO Box 320, Earlysville, VA 22936.

Herbal Advantage, Rte. 3, Box 93, Rogersville, MO 65742; 800-753-9929; www.herbaladvantage.com.

Horizon Herbs Seed Farm: 541-846-6704; fax 541-846-6233; hhcusrserv@HorizonHerbs.com; PO Box 69, Williams, OR 97544; www.HorizonHerbs.com.

Le Jardin du Gourmet sells herbs and seeds: 802-748-1446; PO Box 751, St. Johnsbury Center, VT 05863-0075; www.ArtisticGardens.com/

Linda’s Garden offers a complete herb and herb line. 1436 Campbells Landing Rd., Virginia Beach, VA 23457, 757-426-5303; herb@cyber9.com; www.cyber9.com/herbs.

Long Creek Herbs: Call/fax 417-779-5450; Rte. 4, Box 730, Oak Grove, AR 72660.

Mulberry Creek’s Herb Farm offers a very large selection of certified organic herbs, stevia plants, etc. Free catalog: 419-433-6126; 3312 Bogart Rd., Huron, OH 44839; www.mulberrycreek.com.

Nichols Garden Nursery is an herb specialist that’s been around longer than this book, selling a wide variety of herb plants and seeds; 1190 N. Pacific Hwy., Albany, OR 97321; www.gardennursery.com/; 541-928-9280; fax 800-231-5306.

Redwood City Seed has a great herb collection: 650-325-7333; PO Box 361, Redwood City, CA 94064; www.ecoseeds.com.

Richer’s is an herb specialist offering 900+ culinary, medicinal, and ornamental varieties including stevia and yucca. Free catalog: 905-640-6677; fax 905-620-6641; 357 Hwy. 47, Goodwood, Ontario, L0C 1A0, CANADA; info@richters.com; www.richters.com.

Sandy Mush Herb Nursery offers 1,850 varieties of culinary and tea herbs; decorative, scented geraniums; dye plants, etc. Their $5 catalog fully describes all those plants, their growing conditions, and uses; plants for various purposes and places; growing and using herbs; recipes; herb books; and sample plans for kitchen, bee, butterfly, fragrant, and geometric culinary gardens: 828-683-2014; 316 Surret Cove Rd, Leicester, NC 28748-2014; brwn.org/sandymushherbs.

Southern Exposure Seed Exchange uses organic/sustainable methods and has an extensive online catalog: PO Box 460, Mineral, VA 23117; www.southernexposure.com.

SELLING HERBS: This isn’t necessarily easy. But you might do well selling herbs at a farmer’s market, either in peat pots, in hanging pots, or cut for culinary use. Develop a personal clientele. Herb growers, by definition, are supposed to be 100% organic, because the Environmental Protection Agency has not authorized any pesticides for use on herbs. And wholesalers won’t buy herbal products unless growers can certify they are chemical free. (However, spot checks have found poison residues in some commercial herb products.)

For good information from a pro herb wholesaler for both beginners and other pros, see The Potential of Herbs as a Cash Crop by Richard Alan Miller or Profitable Herb Growing by N. P. Nichols. Growing and Selling Fresh-Cut Herbs (1999), by Sandie Shores, covers crop production methods, including in a greenhouse (www.freshcutherb.com). Lee Sturdivant’s Herbs for Sale focuses on small-scale growers selling herbs. The ATTRA brochure “Herb Overview,” including an extensive resource list, is available free (800-346-9140; www.attra.org/attra-pub/Herb.html). The American Herbal Products Ass’n (AHPA) is at 301-588-1171; fax 301-588-1174; 8484 Georgia Ave., Ste. 370, Silver Spring, MD 20910; apha@apha.org. Their website posts news such as “German health authority has cancelled all registrations for products containing kava,” and “New bill limits the use of the name ‘ginseng’... to ingredients derived from the genus Panax” at their great website: www.apha.org.

If you’re interested in the flower market, a valuable article on “Cut Flower Production” is at www.attra.org/attra-pub/cutflower.html. And read Lynn Byczynski’s 1997 book, The Flower Farmer: An Organic Grower’s Guide to Raising and Selling Cut Flowers (Chelsea Green). It has info on varieties to grow, picking a site, harvesting, marketing, and arranging. Join the Association of Specialty Cut Flower Growers: 440-774-2887; fax 440-774-2435; P.O. Box 268, Oberlin, OH 44074; www.ascfg.org. Also, network with and learn from other herb sellers by joining the Herb Growing and Marketing Network www.herbworld.com. For local networking, just look in your Yellow Pages under “Herbs.”

Harvesting Herbs

NOTE: If you want to gather wild herbs, keep in mind that roadsides, fields, and even forests can get unannounced and unrecorded but heavy doses of herbicide or insecticide. Be cautious.

WHEN TO HARVEST: Gather herbs on a dry day, early in the morning but after the dew is off. The season to harvest varies with the species. Parsley and chervil are dried in May, June, and July; burnet and tarragon in June, July, and August; marjoram and mint in July; summer savory and lemon thyme at the end of July and August. The tender young leaves that appear before the flowering are usually best. Get
leaves before the plants show signs of going to seed. That happens after they blossom, when the blossoms turn into seed clusters and their energy goes into making seed. At best the plant is not at its prime; at worst it gets bitter.

**HOW TO HARVEST:** Cut the herbs with pruning shears or scissors and put them into clean pillowcases or some such. Don’t cut to the ground; leave at least a 4-inch stem if you’re topping an annual. If it’s a perennial, leave at least two-thirds of the plant unharmed. Then take the herbs home and carefully pick them over. Rinse in cool water and drain.

### Preserving Herbs

If you can’t pick from your herb plants all winter long or bring some into the house in pots, you can either freeze or dry your herbs for winter use. Whether freezing or drying, label all containers. Frozen and dried herbs tend to look alike, and you may not be able to smell the difference.

**FREEZING:** Wash if needed, shake off excess water, package in small amounts in baggies or boxes, and freeze right away. Herbs that freeze well are anise, basil, chives, coriander, dill, lovage, marigold, mint, oregano, sage, savory, sorrel, sweet marjoram, tarragon, and thyme. Take out of the freezer only the amount you intend to use.

**DRYING**

**Outside.** Spread individual leaves or leaves still on the stem (they’ll be easier to get off once dried) on sheets of clean cloth to dry in the shade in an airy place, or dry in a very slow oven or dehydrator. Or put them in an outdoor dryer covered with cheesecloth and place where there’s good air circulation all around. Direct hot sunlight ruins leaves by burning or browning; a little sun early or late in the day is OK. The aromatic herbs shouldn’t be exposed to too much heat, and don’t let them get rained or dewed on.

**In an Oven or Dehydrator.** Spread in shallow pans at 110°F, with the door ajar if you’re using an oven. Don’t mix different kinds of herbs. It takes an average of 8 hours.

**Big Leaf/Small Leaf.** Some herbs are huge plants (as tall as 6 feet high) with real big leaves. Drying big, moist-leaved plants is harder than doing small ones. With comfrey, borage, and costmary, you can tear the midrib away from the rest of the leaf and then tear the rest of the leaf into smaller pieces. That helps the leaves dry better and prevents mold. Or hang these big leaves individually to dry.

Mint, lemon balm, and most other small-leaved kitchen herbs easily dry in the shade within 3 days. Tearing the small leaves away from the stem (which can then be discarded) speeds up the process. The problem with tearing the leaves is that they don’t hold their flavor as well.

Turn all drying leaves once or twice a day. Keep good air circulation. Thick leaves tend to be better frozen than dried.

**Roots.** Herb roots are generally better fresh rather than dried. Dig in the fall after the leaves are dead and the roots are mature, or before they start growing again in the spring. Wash in cool water. Dry in a place that’s warm enough to dry them soon but that’s not exposed to the sun, such as an attic. Or slice and dry in a shady place where air circulation is good. Dry in the sun or oven only if you can’t dry them completely the first way. Store when thoroughly dry and brittle. If protected from extremes of heat and cold, the roots will keep fine for years. Store so as to protect them from the air as much as possible.

**Seeds.** To save herb seeds, pick the entire stalk when the seedpods are fully formed but have not yet burst. Spread the pods on a cloth in the sun to dry. If it takes more than one day, stir occasionally while they are outside and bring them in at night. When your seeds are dry, shell and store them in a tightly covered container in a cool, dry place.

**Flowers.** Don’t bruise or overheat. Collect just after they have bloomed. Don’t pile them up, dry on a screen if possible. Harvest orange flowers and elderberry flowers in May, June, and July.

**Storing Dried Herbs.** To store leaves, seeds, or roots, I use baby food jars, cleaned, dried, filled, and with the lid on tightly. Keeping herbs in airtight containers helps prevent flavor deterioration. The fewer times you open the lid, the better they keep their strength. And try to keep them in a cool, dark, dry place away from heat—not on a shelf over or beside your stove! The cool storage inhibits evaporation of the flavoring oil in the herb, and the darkness protects the color, which fades when exposed to light.

**Cooking with Dried Herbs.** They are at least 3 times as strong as fresh. So figure 1 t. dried herb equals 1 T. chopped fresh herb. Another way to figure it is about 1 t. dried herb in a dish for four.

My head just does not want to work this morning. I have so many things to do, and my brains are moving like molasses in January. Mike said an angry word as he went out the door to work, and I’m not going to be right all day. Dear God, make that be a lesson to me to really watch my tongue and speak only kind and loving things. God, if I deserve it, make me a better person. Guide me, Lord. Sometimes things get so confusing. Sometimes I’m not sure what it is You really do want me to do. Help me to get everything done that I’ve got to do. Thank You for the joy to come.
PRODUCTS AND PROCESSES

BUTTER: To make herb butters, start with either salted or unsalted butter, as you prefer. Soften the butter and cream into it finely chopped herbs to your taste. Chives, minced garlic, or watercress are fine additions. You may want to add a little lemon juice. Use 1–2 T. (well-packed) fresh herbs or 1–2 t. dried ones per 1/4 c. butter. Use the herb butter on bread or hot meats, or with eggs. Unsalted butter won't keep as well as salted, but it's best for people who are watching their blood pressure.

CANDYING LEAVES AND FLOWERS: Mint leaves, rose petals, and the blossoms of borago, orange, lemon, lilac, sweet pea, and violet can all be candied. Dip in an egg white that's been stiffly beaten, flavored, and colored to suit. Coat with sugar. Then dry in a 110°F oven (door ajar) or dehydrator.

CANDY, HERB-FLAVORED: For a basic recipe, see "Horehound" under "Alfalfa to Yucca—Garden to Table."

CRYSTALLIZING: To crystallize angelica stems, very thin slices of fresh ginger root, rose petals (damask and cabbage roses are especially good), etc.: Cover the item to be crystallized with water. Boil 5 minutes. Drain. Repeat that process 3 more times. Save the liquid used to boil the item the fourth time. After cooling, measure the liquid and its herb contents by volume and add sugar equal to its volume plus a half more. Boil the herb/water/sugar until the herb gets a translucent quality. Drain the herb, dry it, and roll in white sugar. This keeps well if stored in sealed jars. (For another recipe, see "Angelica" under "Alfalfa to Yucca—Garden to Table."

DYE: Homemade colorings from herbs and other food products are more soft and subtle than artificial ones. Here's what you can use to make different colors:

• Black: barberry leaves
• Blue: blueberries
• Brown: nut hulls (walnuts are best), tea, coffee, rose hips, tobacco, hickory chips
• Green: beet tops, sunflower seeds, birch leaves, Spanish onion skins (outer leaves only), elderberry leaves, spinach, cabbage, rhubarb leaves
• Orange: orange juice
• Pink: cherries; beet and sassafras roots
• Purple: blackberries, cherries, huckleberries, cranberries, raspberries, grapes, purple cabbage
• Red: red onion skins, bloodroot, fresh beet juice, madder root, and logwood
• Yellow: the stem, leaves, and flowers of apple bark; barberry stems and roots; cinnamon; curry; ginger; the stems, leaves, and flowers of goldenrod; hickory bark; mustard; paprika; pear leaves; saffron; tanglewood stems; turmeric

Natural Food Coloring. For a brown color, use a little browned flour, a little burnt sugar, or caramel. Pounded, uncooked spinach leaves make a rich green. Adding some spinach leaf puree makes a lovely deeper green. This green can also be used to tint icings, desserts, etc. Another way to make a cooked-spinach green coloring is by washing some spinach, boiling it until tender, and pouring off the juice for your coloring extract. For a stronger green, let the spinach cool, squeeze dry, mash by pounding, and then put through a sieve. Cooked green peas make a lighter shade of green; split pea soup makes a very pale green color. The coral of a lobster pounded and put through a sieve yields red, as does vinegar or water that has stood on sliced boiled beets. See "Easter Eggs" in Chapter 9 for more information.

Color Blending Chart. Commercial vegetable colorings can be varied like this:

• 2 drops yellow, 1 drop green, and 1 drop red = blue
• 1 drop red, 2 drops green, and 1 drop blue = gray
• 2 drops blue + 1 drop green = dark green
• 3 drops yellow + 1 drop blue = light green
• 12 drops yellow and 1 drop green = olive
• 2 drops red + 1 drop blue = orchid
• 3 drops red + 1 drop yellow = orange
• 3 drops red, 4 drops yellow, and 1 drop green = tangerine

Secrets of Dyeing Fabric with Herbs
NOTE: Dyes and mordants (substances used to set the dyes) are often poisonous. Keep them out of the reach of children. Don't use them in regular cookware.

1. Use an enamel kettle for dyeing. Don't dye in aluminum, iron, or tin pans; these metals can affect the mordant chemistry and color.
2. Herb dyeing is not an exact science. Plant colors can vary, even between one batch and the next. The soil the plants grew in, the amount of rainfall, the light intensity, and the time of year all can affect the color yield.
3. Flowers are the best bet for getting color from a plant, but stems, roots, leaves, fruits, and vegetables may make color too. In general, start with a weight of plant product equal to the weight of fabric you plan to dye.
4. Steep, heat, or even boil the plant until you have a heavily colored liquid; that is your dye. Experiment with a small amount to see if boiling improves extraction or if it makes the color dull.
5. A mordant sets the dye into the dyed substance, making it permanent and often brighter, even under the stress of machine-washing. Alum, acetic acid (from vinegar), and ammonia are mordants. Different mordants can give you completely different colors. Coreopsis plus alum results in a beautiful yellow. Coreopsis plus potassium dichromate (another common mordant) gives brick red. In a pinch you can use lemon juice, salt, or white vinegar as mordants.
6. Natural fabrics like linen, wool, and cotton, jute, silk, and rayon (which is cellulose-based) take herb dyes best.
7. Make your dye first and have it ready. Then wash the material to be dyed, soak it with the mordant, and finally dye it.
8. To dye fabric, heat it very gradually in the colored water up to almost the boiling point, and then cool it down equally gradually. Don't actually boil it. Or soak in the color for at least 1 hour. In the case of silk, keep below 160°F

EXTRACT: An herbal extract is an herb's essence or oil in a solution, usually with alcohol. Extracts and pure oils are used to make scented candles, soaps, and cosmetics like...
peppermint-flavored toothpaste, and to flavor candies and baked goods. Certain ones are also used in mixtures to repel insects from people and plants. Gather fresh herbs and pound to a pulp with a mortar and pestle. Let the plant parts concern stand in pure distilled vinegar, alcohol, or corn, sunflower, or olive oil. Getting 180-proof edible alcohol to make an alcohol-based extract isn’t as simple for us as it was for Great-Grandmother, but you can substitute vodka—it’s half water and half alcohol, equal volumes in 100 proof. Use 2 T. pounded herb to ¾ c. liquid. Or put your herbs, berries, etc. into a bottle and cover with liquid. The liquid then gradually absorbs the soluble parts of the plant. Shake daily for 3 weeks. Keep at a warmish temperature—in the sun, for instance.

> **CITRUS EXTRACT**  Peel away the fruit’s outermost skin, called the zest. (There’s a special tool for this at kitchen stores.) Don’t use any of the white pith. Fill a wide-mouthed bottle one-third of the way up with zest. Pour in vodka for the other two-thirds. Soak 2 weeks, shaking twice daily. Strain and bottle your extract.

> **CLOVER-ROSE “HONEY”**  For this old-time homemade honey substitute, in the summer gather and dry about 90 white and 90 purple clover blossoms, plus 25 sweetbrier rose leaves. Add 10 c. sugar, 5 c. water, and cook together. Sieve out solids. Cook to a syrup consistency.

**GROUND HERB OR SPICE:** Ginger root was once invariably sold intact, and people grated their own. The same cooks also crushed their cinnamon bark and ground their cloves. Now you can take your choice, but the more freshly ground, the better tasting. So when buying, figure the more whole the better, and grind it yourself at home as needed. Whole spices store well and keep their strength a long time. So equip yourself with an old-fashioned mortar and pestle, “spice mill,” or pepper or salt grinder; or grind herbs in your blender or juicer. With those you can also mash seeds, crush dried herbs, and so forth. You grind in your blender or juicer. With those you can also mash seeds, crush dried herbs, and so forth. You grind in your blender or juicer. With those you can also mash seeds, crush dried herbs, and so forth.

The old-time spice mill was a little hand-cranked grinder with a box to catch the ground spice.

**HAND LOTION:** Immerse ¼ oz. gum tragacanth (from Indiana Botanic Gardens) in water and soak for several days. Combine 2 oz. glycerine and 1 oz. alcohol. Strain the gum tragacanth solution and add the liquid to the glycerine/alcohol solution. Scent with herbal or floral extract (rose, lavender, rosemary, etc.). Add enough distilled water to make it the thickness you want; 2 cups is about right. See also “Quince” in Chapter 6 and “Sheep, Lanolin” in Chapter 11.

**COOKED-OUT OIL:** Start with as much as possible of your fresh herb or flower. Lavender or lilac flowers, mint leaves, rose petals, rosemary, thyme, and basil all work well. Press them into a crock, using enough pressure to slightly bruise them. Carefully pour rain or distilled water over them until they are covered. Set the crock outside in full sun, in a place where it will be undisturbed. (Bring inside only to avoid rain.) It takes around a week for oily scum to develop on the water’s surface. Using a small bit of cotton to absorb it, get that oil out of the crock. Squeeze it out into an appropriately small, dark-colored glass bottle. Don’t put the lid on yet. The next step is to cover that container with cheesecloth to keep dust from getting in but allow all the water to evaporate. After a few days, you can go ahead and seal the bottle tightly.

**JELLY:** Basically you combine a juice (grape, orange, cranberry, etc.) with an herb or spice (or both). Tarragon, mint, sage, rosemary, and thyme are good for this; allspice, ground and whole cloves, ginger root, and stick cinnamon are good spices.

**MODERN** Prepare 4 half-pint jars. Heat 1 cup of your juice to boiling. Then pour it over ¼ c. fresh herb (or 1½ T. dried herb) or 2 T. whole spice. Let soak for half hour. Strain into nonaluminum pan. Add 2 more cups of juice, 2 T. vinegar, and 3 c. sugar. Mix and boil, stirring constantly. Now mix in ½ bottle pectin; boil another minute, still stirring. Remove from heat. Stir in food coloring at this point if you want it. Pour immediately into ½ pint canning jars. Put on lids. Process 10 minutes in boiling-water bath.

**OLD-TIME** Prepare jars to hold 10 cups. Coarsely chop 6 lb. tart apples, put into non-aluminum pan, add just enough water to cover, and cook half hour or to softness. Then pour into jelly bag over bowl and let drain overnight. On the next day, measure the juice. Add 2 c. sugar for each 2½ c. of juice. Stir sugar into solution over low heat. Add herbs or spices, or a mix of them, tied into porous bag, and simmer until jelling point is reached. Remove bag and pour into jars. Process 10 minutes in boiling-water bath.

**OIL:** Herbs get their flavors from their natural oils. When herbs are dried the oil is still in there, but it’s concentrated, which is why it takes less in volume of dried herb to give the same amount of flavor. In general, one drop of an “essential oil” is comparable to one handful of fresh dried herbs. Rose, lavender, violet, and lemon balm make good oils. If you do it right, the oil will have a strong scent of the plant, and you can use it like perfume or add a drop to your potpourri or homemade cosmetics. To make an herbal “oil” or “essence,” there are several methods. For any particular plant, one works better than another, so experiment. Best of all, read Potpourri, Incense and Other Fragrant Concoctions by Ann Tucker Fettner, a thorough, accurate collection of everything you need to know about perfume ingredients and the extraction of scents, including recipes.

**SUN-EXTRACTED OIL:** Put your crushed (“bruised”) plant materials—flowers, leaves, bark, or roots—into a bag. Put the bag into a kettle of water and simmer about 24 hours over a slow fire. Then slowly cool. Skim the oil that rises to the top of the water. The bag is used because it almost invariably floats, and it’s easier to get the oil separated that way. Squeeze the bag to help get the oil out. You can even
Any size from a tiny bead up. Pound your ingredients in a mortar and pestle or some such. Place it in a small bottle—about 2 T. herb for a 1-cup bottle. Pour a quality cooking oil over the pounded herb until the bottle is nearly full. Add 1 t. distilled vinegar. Cover tightly. Place where it will stand in hot sunshine every day. Shake twice a day for 3 weeks. Then your pomander is done. It can be used in hot sunshine every day. Shake twice a day for 3 weeks. Strain and it is ready to use.

**EDIBLE OILS**

**Oil, Herb-Flavored for Cooking:** Make the above oils by the pint or quart for wonderful herb-flavored oils for salad dressings and cooking.

**Ointment:** See “Salve.”

**PASTILLES:** Also called scent balls. Same contents as sachets, herb pillows, and potpourri, except that they’re melted together with a gum resin that makes them hard. Any size from a tiny bead up. Pound your ingredients in a smooth-sided mortar together with gum tragacanth, and moisten with a little rose water until you have a mixture that is like a dough. Shape and dry. Can be polished on a lathe. Can be sculpted into jewelry and so on; to make beads, pierce pastilles with a needle while they are still soft.

**Physick:** An old-time word for any plant-based medicine.

**Pillows, Herb:** See “Sachets and Herb Pillows.”

**Pomander:** A mixture of aromatic or fragrant substances enclosed in a bag or box that has holes in the sides. The pomander ball is used to scent clothes or linens; in old-time usage it was worn on the body to guard against infection. The pomander ball was most often made of amber or a partially dried orange with cloves stuck into it. To make one, start with a thin-skinned, small orange and a handful of cloves. Press the point of each clove into the orange as you would a thumbtack into a wall. Continue until the orange is quite covered with cloves, with only their large “heads” sticking out. Now roll the orange in ground cinnamon, getting as much of it on as you can. Set on paper in an airy place and let dry for 3 weeks. Then your pomander is done. It can be placed in the traditional box or hung by a ribbon.

**Potpourri:** That’s pronounced “po-e-purree” (it’s French). The purpose of a potpourri is fragrance, but sometimes it can be very beautiful too. One formula is 1/6 any flower petals, 1/6 herbal leaves, and then just a few added spices and/or dried citrus zest. (For more potpourri recipes, see “Geranium” and “Rose” under “Alfalfa to Yucca—Garden to Table.”) The container should be china or pottery with a lid you can close tightly. Keep that lid on tight after the potpourri is made, except when you want to scent a room; then uncorking for half an hour should do it. I don’t recommend using a glass container because light deteriorates potpourri; on the other hand, I’ve seen beautiful potpourris in glass bowls that were wonderful to both see and smell. When they deteriorated, the potpourri was simply replaced.

**Using Herbs.** A tablespoon or two of fragrant leaves adds to your potpourri’s interest, but be cautious of adding more, because they may get overwhelming. Try rosemary, bay leaf, marjoram, cedar or balsam needle, basil, mint, sage, lemon verbena, scented geranium, sweet briar, lavender, southernwood, sweet cicely, lemon balm, bergamot, myrtle, costmary, eucalyptus, chamomile, thyme, or anything else that catches your nose’s attention. Also consider adding the flowers of rosemary and thyme.

**Using Flowers.** Although potpourris may contain many different ingredients (flowers, fragrant leaves, and spices), traditional potpourris were at least four-fifths rose petals—especially damask, moss, or gallica roses. You can make the other one-fifth any kind of sweet-smelling flower, or just use straight rose petals, or create your own flower mixes. Suitable additional flowers are acacia, bergamot, calendula, carnations, heliotrope, honeysuckle, hyacinth, jasmine, jonquil, lavender, lemon verbena, lilac, lily of the valley, mignonette, myrtle, narcissus, lemon or orange blossom, pansy, peony, philadelphus, pinks, stocks, thyme, violet, wallflower—or any combination of flowers you want to try. Use any fragrant petals so long as they’re thin enough to dry well. Patricia Wiley, Watsonville, CA, wrote me, “Don’t forget to include some small buds, as they add their personality to the dried mixture.”

**Drying Herbs/Flowers.** Choose a dry morning to collect the herbs and flowers—after the dew has dried. Pick blossoms that have just fully opened early in the day. Don’t pick roses that have already been fully open for several days. Don’t use roses that have been in a vase for a week; most of their fragrant oils will be gone. Collect about four times as much as you expect to need, because they shrink in drying. Use the petals and buds of flowers only. Pull them carefully from the rest of the flower, which you discard. Dry them away from light, spread them out in a shallow layer on clean paper or cloth, and stir a couple of times a day. Dry to a papery state.

**Using Spices.** Two or three teaspoons of crushed spices add fragrance, but be careful not to use too much. Good spices to use are cloves, cinnamon, nutmeg, mace, coriander, aniseed, or allspice. Or you could put in a slice of lemon or orange peel stuck full of cloves.

**Using Liquids.** Traditional potpourris were either dry or moistened with fragrant oil. You can add a few drops of a fragrant oil like eucalyptus, lemon verbena, peppermint, rose geranium, or rosemary oil, or another strong scent like brandy or attar of roses. Add 1 drop at a time, and stir with a wooden spoon.

**Fixatives.** The fixative both acts as a preservative and helps to hold the scent. Rose expert Patricia Wiley wrote me, “A
modern fixative is isopropyl alcohol, sprayed on. Do not use any fixative until potpourri fragrances have had time to sit and blend together, about 3 weeks." Combine the scented materials with the fixative by layering—a layer of potpourri, then a layer of fixative. Pack into jars, seal tightly, and let rest 2–4 weeks. Your fixative can be a few dashes of orrisroot, or much more. You can grow and process it yourself or buy from an herbal supplier. An orris/salt fixative is made by mixing one-third orrisroot powder with two-thirds uniodized salt for your fixative. An antique Elizabethan fixative was made by combining 1/4 oz. gum benzoin, 2 oz. orrisroot, and a spoonful of brandy. Gum benzoin can also be used alone for this purpose.

**Using Potpourri** Stir it. Moisten it with a little rose water, add a drop of fragrant oil, use as is as a source of room fragrance, or pack it into little cotton sachet bags. Every couple weeks or so, stir the potpourri bowl a little to release new fragrance.

**POULTICE:** A poultice is a bag of hot herbs held against an aching or infected portion of the body. Comfrey leaves make a healing poultice. Another traditional one is a bowl of hops mixed with a cup of hot vinegar. A poultice of boiled mullein leaves is good for cuts on animals. Chop green leaves finely and soak them a bit in almost boiling water. Let them cool before you put them on so they don't burn the patient. Then put them on the hurt place. You can make the poultice stay on by putting a cloth over it or wrapping the leaves in a clean cloth. Don't leave a cold poultice on; have a fresh one ready to go on when you take off the cooling one. Don't reuse the herbs. This may sound spendthrift of herb, but comfrey (the #1 healing herb) grows huge, so you'll have all you want once it gets a good start in your garden.

**LINSEED POULTICE** To help aching bodies, scatter 1/4 lb. linseed into 2 c. very hot water, stirring constantly. The mixture will gradually turn into a dough. Mix in 1/2 oz. olive oil. Spread that thickly over a piece of prewarmed cloth. Fold over the extra ends of the cloth to make a sort of bag, and place the poultice on the hurting part.

**POWDER:** An herb powder is simply bark or dried herbs pulverized to a powder in your mortar.

**SACHETS AND HERB PILLOWS:** These are cloth "pillows" made to hold dried, crushed herbs and flowers. Sachets are tiny bags meant to be placed in a drawer or closet to scent clothing, sheets and pillowcases, or stationery. Herb pillows are several times larger and are traditionally used to overcome a sickroom smell and soothe nerves.

You can experiment to get your favorite scent. Lavender is traditional, but don't be afraid to try other mixtures. Lilac, rose petals, sweet peas, mint, rosemary, and thyme are all suitable. Or use lavender, sage, peppermint, and lemon balm in some combination, or sage, peppermint, and lemon balm without lavender. (For more ideas, see "Potpourri.") If you are making sachets intended to keep moths away, try a mixture of the insect-repellent herbs: cotton lavender, mint, rosemary, rue, southernwood, tansy, and wormwood.

As in the case of potpourris, the scent, whatever its source, will not last. To renew scent, every couple weeks or so, crush the sachet bag a little between your fingers to break some herbs and expose a new supply of their fragrant oil for scent. The aromatics will eventually run out; potpourris need to be refilled at least every year.

**Preparing the Contents.** Follow potpourri instructions. Once your planned ingredients are harvested and dried, mix them and grind to a powder in your spice mill, mortar, or blender/food processor. Add a fixative like orrisroot. (See "Fixatives.") If you are making a quantity of powder at once—more than you need to fill your sachets or pillows—store in a small tightly-lidded bottle in a cool place and protect from the light.

**Making the Sachet** Pack the powder into "pillowcases" of cotton, and sew up the open side. You can make a large herb pillow by sewing together two men's handkerchiefs. You can cover the inner pillow with velvet, gingham, percale, ribbon-trimmed lace, or any other scrap material you have. To hang or pin in place, sew a loop of ribbon or bias tape into one corner as the fourth side is sewn. Just make sure the material and the seams are tight enough so that dust from the contents doesn't leak out.

**HEADACHE PILLOW** A midwestern pioneer recipe. Mix together 1/2 oz. cloves and 2 oz. each of lavender, marjoram, rose petals, and betony rose leaf. Proceed as above. You're supposed to sniff it to cure your headache.

**TO-EASE-MELANCHOLY-AND-PUT-YOU-TO-SLEEP PILLOW** Mix 2 oz. rose petals, 1 oz. mint, and 1/4 crushed clove for pillow.

**HERB SACHET** Mix 1 part each dried sweet basil, dried thyme, dried marjoram, and dried rosemary leaves. With this one you don't need any fixative.
SAVILE: This is a mixture of herb with a carrying agent that you rub onto the problem area. Gen MacManiman, who sells all sorts of food-drying information and supplies, is not only a food drying expert but also an herb lady! She wrote me, “For the base, salves and ointments use various wax/oil mixtures. An olive oil and beeswax combination is most commonly used. Freshly rendered lard is an excellent salve base. It has healing virtues and is just the right consistency. If stored in a cool place, it will keep a long time.”

CHICKWEED OINTMENT Gen MacManinan’s recipe: “Warm one cup lard in the dehydrator (Lard becomes fluid at low temperatures—80–100°F) Add ½ c. dried, powdered chickweed, and mix well. Return the mixture to the dehydrator and dry it for two days at 100–110°F. The fluid will then be quite green (the greener, the better) and ready to strain and place into containers. Store in the refrigerator or a cool cupboard. This is very healing for any abrasion or scratch, but best of all, it instantly takes the itch out of a mosquito bite! Try it on any itch.”

BALM OF GILEAD SALVE This is good for cuts, scrobes, and chapped hands. The main ingredient is the sticky, brownish buds of the black cottonwood (Populus trichocarpa), commonly called balm of Gilead. It grows wild, west of the coastal Rockies, from California to Alaska. Pick the buds in spring before the green leaves form. Make sure you get the buds at the sticky stage. Put them into a big tin can, because be easiest if you can just throw it out after you’re done. Add enough lard to just cover the buds when the lard has melted. Don’t use cooking oil—you’d get liquid instead of solid salve. Simmer the buds/lard mix on low heat 2–3 hours. Then strain into sterilized jars or cans. You’ll end up checking out the straining cloth, so make it something you can do without.

SHAMPOO: You can make your own herbal shampoos. Start by finding a jar with a lid. Pour into it 1 T. olive oil, 1 bottle Castile soap, and 2–3 t. of your favorite culinary herb. Lemon verbena, rosemary, and thyme are good choices. Mix your ingredients well with a wooden spoon. Put the lid on the jar and let the contents rest in a dark, cool place for about a week. Then strain to get the solids out. What remains is your herbal shampoo. Or you can use it as a hand or body soap.

SIMPLE: A plant medicine.

SPIRIT: A solution of an herb made with brandy is called an herb spirit. The basic recipe for herb spirit is to use fresh herbs, picking just before flowering or when otherwise appropriate. Strip the leaves from the stems and pack lightly in a jar. Fill the jar with brandy and cover tightly. Let rest for a month. Strain and bottle.

HERB SPIRIT FOR SEASONING SOUPS Equal parts sweet marjoram, basil, thyme, savory, and parsley. Measure and mix before filling the jar. Proceed as above.

SYRUP: You make an herbal syrup, used as a beverage or a medicine base, by adding simple syrup (sugar and water) to the herbal infusion when hot and somewhat evaporated. Bottle and seal when hot. Violet flowers make an excellent syrup.

TEAS: We gather wild mint for tea down along Brady Gulch Creek, which runs along the bottom of our canyon, and wild strawberry leaves from the tender little plants that grow in the timbered places. You can drink teas and coffees made from the dried leaves and stems of many plants, from barks and nuts, and from grains too. In colonial America, when tea drinking became unpatriotic during the Revolutionary War (remember the Boston Tea Party!), the conventional China tea leaves were replaced by raspberry leaves, loosestrife, hardtack, goldenrod, dittany, blackberry leaves, sage, and many others. Some other homemade drinks enjoyed on the frontier were teas made from wild rose hips, mint, oat straw, salsaparilla, and the marrow from beef bones. Rye and chestnuts, ground and roasted, or roasted crushed barley alone, were made into “coffees.” Those alternative teas and coffees contain no caffeine.

Of Infusions and Decoctions. Those two aren’t exactly the same thing. A decoction is made by boiling an herb in water (an average of 10 minutes) and straining while hot. Coffee is a familiar decoction. An infusion is made by pouring hot water over an herb and then letting it steep. In general, leaves and flowers are steeped; roots and seeds are boiled. That’s why flower/leaf drinks are “teas” and dandelion/chicory root drinks are “coffees.”

Leaf Teas. They’re easy to make. Just boil water and measure out your herbs: from 1 t. dried to 1 T. fresh herbs for a cup of water, or from 1 T. dried to 1 c. fresh for a quart, depending on the strength of the herb. Then use one of the following methods.

- Pour water directly over herbs in teapot. To serve, put a little strainer over your cup and pour through that.
- Put your leaves or flowers into a tea ball or into a strainer. Set that into the cup and pour the hot water over it. Pour over leaves and let set 2–10 minutes. You really must experiment to get it just right. Every herb is a little different, and so are tastes. On average, the leaves are steeped in the hot water for 5 minutes. Get to know your teas, and you’ll be able to judge by the color when you have the desired strength. Too little soaking and the tea will be too weak; too much and it will be bitter. Sweeten with brown sugar or honey to complement the taste of herb tea. You can freeze your leftover tea to use for quick servings, but strain out the herbs first, or it will get too strong.

- For health tea, add to just-boiling water 1 handful fresh chamomile, 1 bunch lemon balm (or ½–1 oz. dried, or ¼ c. lemon juice), and 1 bunch peppermint. Cover and steep 20 minutes. Add honey to taste. (If lemon juice is used instead of lemon balm, add it before honey.) Stir well. Put in jug in the refrigerator and dilute to taste as you drink it.

- For health tea, add to just-boiling water 1 handful fresh chamomile, 1 bunch lemon balm (or ½–1 oz. dried, or ¼ c. lemon juice), and 1 bunch peppermint. Cover and steep 20 minutes. Add honey to taste. (If lemon juice is used instead of lemon balm, add it before honey.) Stir well. Put in jug in the refrigerator and dilute to taste as you drink it.

- For health tea, add to just-boiling water 1 handful fresh chamomile, 1 bunch lemon balm (or ½–1 oz. dried, or ¼ c. lemon juice), and 1 bunch peppermint. Cover and steep 20 minutes. Add honey to taste. (If lemon juice is used instead of lemon balm, add it before honey.) Stir well. Put in jug in the refrigerator and dilute to taste as you drink it.

- For health tea, add to just-boiling water 1 handful fresh chamomile, 1 bunch lemon balm (or ½–1 oz. dried, or ¼ c. lemon juice), and 1 bunch peppermint. Cover and steep 20 minutes. Add honey to taste. (If lemon juice is used instead of lemon balm, add it before honey.) Stir well. Put in jug in the refrigerator and dilute to taste as you drink it.

- For health tea, add to just-boiling water 1 handful fresh chamomile, 1 bunch lemon balm (or ½–1 oz. dried, or ¼ c. lemon juice), and 1 bunch peppermint. Cover and steep 20 minutes. Add honey to taste. (If lemon juice is used instead of lemon balm, add it before honey.) Stir well. Put in jug in the refrigerator and dilute to taste as you drink it.

- For health tea, add to just-boiling water 1 handful fresh chamomile, 1 bunch lemon balm (or ½–1 oz. dried, or ¼ c. lemon juice), and 1 bunch peppermint. Cover and steep 20 minutes. Add honey to taste. (If lemon juice is used instead of lemon balm, add it before honey.) Stir well. Put in jug in the refrigerator and dilute to taste as you drink it.

- For health tea, add to just-boiling water 1 handful fresh chamomile, 1 bunch lemon balm (or ½–1 oz. dried, or ¼ c. lemon juice), and 1 bunch peppermint. Cover and steep 20 minutes. Add honey to taste. (If lemon juice is used instead of lemon balm, add it before honey.) Stir well. Put in jug in the refrigerator and dilute to taste as you drink it.

- For health tea, add to just-boiling water 1 handful fresh chamomile, 1 bunch lemon balm (or ½–1 oz. dried, or ¼ c. lemon juice), and 1 bunch peppermint. Cover and steep 20 minutes. Add honey to taste. (If lemon juice is used instead of lemon balm, add it before honey.) Stir well. Put in jug in the refrigerator and dilute to taste as you drink it.

- For health tea, add to just-boiling water 1 handful fresh chamomile, 1 bunch lemon balm (or ½–1 oz. dried, or ¼ c. lemon juice), and 1 bunch peppermint. Cover and steep 20 minutes. Add honey to taste. (If lemon juice is used instead of lemon balm, add it before honey.) Stir well. Put in jug in the refrigerator and dilute to taste as you drink it.

- For health tea, add to just-boiling water 1 handful fresh chamomile, 1 bunch lemon balm (or ½–1 oz. dried, or ¼ c. lemon juice), and 1 bunch peppermint. Cover and steep 20 minutes. Add honey to taste. (If lemon juice is used instead of lemon balm, add it before honey.) Stir well. Put in jug in the refrigerator and dilute to taste as you drink it.

- For health tea, add to just-boiling water 1 handful fresh chamomile, 1 bunch lemon balm (or ½–1 oz. dried, or ¼ c. lemon juice), and 1 bunch peppermint. Cover and steep 20 minutes. Add honey to taste. (If lemon juice is used instead of lemon balm, add it before honey.) Stir well. Put in jug in the refrigerator and dilute to taste as you drink it.

- For health tea, add to just-boiling water 1 handful fresh chamomile, 1 bunch lemon balm (or ½–1 oz. dried, or ¼ c. lemon juice), and 1 bunch peppermint. Cover and steep 20 minutes. Add honey to taste. (If lemon juice is used instead of lemon balm, add it before honey.) Stir well. Put in jug in the refrigerator and dilute to taste as you drink it.

- For health tea, add to just-boiling water 1 handful fresh chamomile, 1 bunch lemon balm (or ½–1 oz. dried, or ¼ c. lemon juice), and 1 bunch peppermint. Cover and steep 20 minutes. Add honey to taste. (If lemon juice is used instead of lemon balm, add it before honey.) Stir well. Put in jug in the refrigerator and dilute to taste as you drink it.

- For health tea, add to just-boiling water 1 handful fresh chamomile, 1 bunch lemon balm (or ½–1 oz. dried, or ¼ c. lemon juice), and 1 bunch peppermint. Cover and steep 20 minutes. Add honey to taste. (If lemon juice is used instead of lemon balm, add it before honey.) Stir well. Put in jug in the refrigerator and dilute to taste as you drink it.

Add honey to taste. (If lemon juice is used instead of lemon balm, add it before honey.) Stir well. Put in jug in the refrigerator and dilute to taste as you drink it.
Folks in Wichita also recommended mint leaves in lemonade, raspberry leaves for when you're in labor, and sarsaparilla for any fella who needs more manhood!

**Tincture:** Here's Gen MacManiman's expertise again: "Vinegar tinctures are inexpensive, easy to make, and will last for many years. I have many tinctures which are over ten years old. They are simple to make. Herbs can be used in combination or individually. I use either vinegar or vodka and always use the dried herbs, finely crumbled or powdered. Basic proportions are 1 pt. vinegar or vodka to 2 oz. powdered herbs. Sunlight energizes these tinctures. Set the jar in a window for two weeks and shake twice daily. At the end of two weeks, strain and bottle the mixture. Dropper bottles are great."

**Tisane:** An old-time herb tea, often used with medicinal intent. It's a strong brew given by the tablespoon several times a day.

**Vinegar, Herb-Flavored:** Vinegars can be flavored with leaf herbs, seeds, spices, or combinations thereof.

**Secrets of Making Herb Vinegar**

1. You can start with store-bought cider or wine vinegar or with your homemade. Match strong-flavored herbs to red wine vinegar, mild-flavored ones to white wine vinegar.
2. In general, use 3 T. seeds, 1 c. fresh herbs, or ¼ c. dried herbs per 1 qt. vinegar.
3. Gather your herbs fresh, if possible—the flavor will be more pungent. Crush just before steeping.
4. If you must use dried leaves, moisten them with a little hot water in a bowl before steeping.
5. Heat vinegar to boiling. If you are using seeds or spices, crush them with a mortar and pestle (or crush them in a wide-mouthed jar with a wooden spoon). Boil them in the vinegar for 10 minutes.
6. Pour the vinegar and seeds/spices over the herbs.
7. Cover and let stand several weeks in a warm dark place. Shake the bottle gently twice a day.
8. At or before the end of the recommended period, taste the vinegar. If it doesn't seem flavorful enough, strain and start over with more seeds or leaves.
9. When straining, first use a sieve and then a cloth.
10. When the vinegar suits you, bottle it: Place a fresh sprig of herb inside your long-term storage bottle. Strain your steeped mixture in on top of that. Herbal vinegars are best stored at room temperature.

Here are specific recipes for herb vinegars (in alphabetical order by herb). Burnet (leaves or seeds), marjoram, dill, lemon balm, and chives are other possibilities. Mix and match to suit yourself. For chervil and tarragon vinegar recipes, see "Chervil" and "Tarragon" under "Alfalfa to Yucca—Garden to Table."

- **Basil Vinegar** Combine ¼ c. leaves and 1 qt. wine vinegar.
- **Caraway, Cardamom, Celery Seed, or Mustard Vinegar** Combine 3 T. seeds and 1 qt. white wine vinegar.
- **Garlic Vinegar** Combine 4 cloves garlic, peeled and chopped, ½ t. salt, 2 t. ground cloves, 1 t. freshly ground peppercorns, 1 t. caraway seeds and 1 qt. wine vinegar. Give it 2–3 weeks before you strain and use.
- **Mint Vinegar** Combine 2 c. mint leaves, 1 c. sugar, and 1 qt. cider vinegar. Or pack the leaves into a pint jar and fill the jar with wine vinegar. Let stand 2 weeks or more, then strain. Bottle.
- **Plain Onion, Garlic, or Celery Leaf Vinegar** Use 24 green onions (shallots are best if you have them) or 4 cloves garlic or 2 c. celery leaves, peeled and chopped. 2-3 weeks in 1 qt. vinegar. Strain and use.
- **Multi-spiced Vinegar** Combine 1 qt. cider vinegar, ½ oz. celery seed, ½ oz. dried parsley, 1 clove garlic, 3 small onions, grated, 2 whole cloves, 1 t. peppercorns, 1 t. nutmeg, salt to taste, 1 T. sugar and 1 T. good brandy. Cover in jar. Let stand 3 weeks, strain, and bottle.
- **Hot, Hot Vinegar** Add horseradish, onion, paprika, pepper, chili peppers, cayenne pepper, curry powder—any or all as suits you. Strain and bottle when you like the taste. These aren’t for me, but some people love anything that scalds their gullet.

**Food Seasonings**

**Seasoning Mixtures**

Save your empty spice containers to hold your own mixes! Store seasoning mixes in an airtight container and in a dry, cool place—not over or beside your stove!
**Packaging Seasoning Mixes:** Combine your favorite spices, dried vegetables, and herbs. Lay out squares of foil or small plastic baggies. Spoon 1 serving size of your mix into the center of each foil square or baggie. Seal foil packets by folding over the ends and rolling them. To store in plastic, press the air out and tie tightly shut.

**Spice Bag.** When a recipe calls for a spice bag, put the whole spices listed in the recipe into a handkerchief-sized piece of cheesecloth or some such, tie firmly, and cook right with the dish to be flavored. Remove the bag before serving. Or use a tea ball for the same purpose. It will prevent your friend with an ulcer from biting down on a peppercorn.

**Salt Mixtures**

- **Salty Herbed Salt** In a bowl combine 1 c. salt and 1 t. each dried parsley, chives, onion flakes, and summer savory. Store in an airtight container and use for roll or bread dough and to season salads.
- **Low-Salt Herbed Salt** Combine ¼ c. salt, 2 t. dried basil, 1 t. dried tarragon, 1 t. dried chives, and ½ t. dried oregano. Get it all very fine and well mixed. Good on popcorn, etc.
- **Herb-Salt Mix for Hamburgers** Crumble until fine as possible 1 t. each of dried basil and dried oregano. Mix ¼ c. chopped parsley, the dried herbs, 1 t. paprika, and 1 c. salt. Keep in a salt shaker.
- **Low-Salt Seasoning Salt** Combine ½ t. garlic powder, ½ t. dried lemon rind, ½ t. onion powder, 2 t. paprika, 6 T. salt, ½ t. dried thyme, 2 t. dry mustard, ½ t. curry powder, and ½ t. powdered cumin. Blend well. This is good with anything: veggies, meats, fish, or salad.
- **Sesame Salt** Put into a frying pan and heat gently until the seeds begin to brown (do not overheat): 8 parts raw sesame seeds and 1 part sea salt (available at health food stores). Remove and allow to cool. Mix well and grind. Sprinkle this on foods at the table—soups, salads, entrees—but when you do, leave out any other salt.
- **Salt/Pepper Mix** Keep a shaker of 3 parts salt and 1 part pepper near the stove if you use salt and pepper in practically everything.

**Herb Mixtures**

- **Herb Bags to Season Soups and Stews** In each of several 4-inch squares of cheesecloth combine ½ t. each basil and marjoram, 1 crumbled bay leaf, and 5 peppercorns. Tie the squares into bags with string. Store in an airtight container.
- **Bouquet Garni** This classic French herb mix is packed into little 4-inch packets of cheesecloth. Spread the cloth out flat. Measure into the middle of it 1 bay leaf, 1 t. marjoram, 1 T. parsley, 1 t. savory, and 1 t. thyme. Bring together the corners of the bag and tie them with a string so it looks like a miniature peddler's bag. Good in soups and stews. You can vary it to taste, adding or subtracting herbs as you please.

**Curry Powders:** Curry powder is a mixture of spices—from just a few to as many as fifty. The curry powders sold in grocery stores are usually a combination of 15–20 herbs, seeds, and spices, but people who really know about curry have special combinations of spices to go with various dishes, some of which need mild, subtle seasonings and others hotter ones. The strength of a curry depends on how much chili powder is used. Coriander seed is considered to be the one traditional and most necessary ingredient; other possible ingredients include allspice, anise, bay leaves, caraway, cayenne pepper, celery seeds, cinnamon, cloves, cubeb berries, cumin seeds, curry leaves, dill, fennel, fenugreek (seeds and leaves), garlic, ginger, juniper berries, mace, mint, mustard, nutmeg, oregano, pepper (white and black), paprika, poppy seeds, saffron, salt, and turmeric. Have all ingredients well powdered,
using a mortar and pestle to grind. Sift together and keep in a tightly corked bottle.

- **CURRY MIX #1** Combine 3 oz. turmeric, 4 oz. coriander seed, 2 oz. black pepper, 1 oz. fenugreek, 1 oz. ginger, and ¼ oz. cayenne pepper.

- **CURRY MIX #2** Combine 6 t. coriander seed, ½ t. cayenne pepper, 1½ t. turmeric, ½ t. whole cloves, 1½ t. fenugreek seeds, ½ t. cardamom seed, and 1¼ t. cinnamon.

- **FAVORITE CURRY MIX** From Zubaidah Ismail, Penang, Malaysia: Combine 1 t. ground turmeric, 1 t. chili powder, 1 t. whole allspice, nutmeg, and ginger are other possibilities. Lemon juice and lemon slices are good too. Sweeten with your favorite sweetener. Be sure to strain unless all will be consumed immediately. The longer the whole spices are in it, the stronger the drink gets—and it soon becomes too bitter to enjoy!

- **MULLED CRANBERRY CIDER** Mix 4 c. cider (or grape juice), 4 c. cranberry juice, 6 cloves, 1 stick cinnamon, 4 whole allspice, and ½ c. brown sugar. Heat until the sugar dissolves, and serve hot.

- **MULLED RED WINE** Use the cheapest red wine you can find (it will still be good). Heat 1 qt. wine and add 1 stick cinnamon, juice of 1 lemon, ½ c. sugar, 8 cloves, and ½ lemon sliced into sections. Strain. Serve with a slice of the lemon in each glass.

- **MULLED GRAPE JUICE** Combine 4 c. grape juice (dilute if it is very strong), 4 sticks cinnamon, about ¼ c. sugar, and a dash each of nutmeg, cloves, ginger, and powdered cinnamon. Bring to a boil and serve hot.

- **HOT SPICED TEA FOR A CROWD** Combine 3 qt. boiling water, 3 T. tea leaves, 2 sticks cinnamon, and 1 t. whole cloves. When your tea is strong enough, strain and add ¼ c. sugar, ½ c. lemon juice, and 1 c. orange juice. Reheat. The “tea” leaves can be whatever kind you prefer—raspberry, strawberry, rose hip, etc.

### Sauces

- **WORCESTERSHIRE SAUCE** Pour 1 qt. wine vinegar into nonaluminum pan and heat. Add ½ t. curry powder, ¼ t. shredded and crushed pimento, 1 minced garlic clove, 4 t. cut and mashed green onions, ½ lb. brown sugar, and a pinch each of ginger, pepper, mustard, and salt. Stir into the vinegar, note how high in the pan the liquid is, put on a lid, and cook on very low heat for 1 hour, adding more vinegar occasionally to keep the liquid amount the same. When the time is up, add 2 c. sherry and let rest a week in a warm place. Then strain out the solids and bottle the sauce into sterilized, dark-colored glass. It tastes best if all your ingredients are fresh.

- **KETJAP MANIS (SWEET SOY KETCHUP)** From Ruth, Bonaire, Netherlands Antilles: “Ketjap manis is sweet sauce, and more common than ketjap benteng, or sour sauce. To make it, simmer together equal parts of water, strong Japanese soy sauce, and molasses, and jazz it up with fresh or ground ginger, coriander, and pepper. It’s basically a sweetened, thick, and rather spicy soy sauce, like North American ketchup!”

By the way, some years back I received a letter scolding me for using the word “catsup” to describe a thick sauce. The writer explained that the origin of the word “ketchup” was “ketjap,” a Malay term for any thick sauce and not a trademark of Hunt’s, etc. He wryly commented that the only meaning of “catsup” that he could figure out had to do with the position of a cat rather than a thick sauce!

After Ruth sent me that ketjap recipe, I knew he was right. The situation has gotten so far from the truth that even the dictionary calls “catsup” the real thing—and “ketchup” only a “variation.” And it defines “catsup” as a *tomato* sauce, which is so incorrect it boggles my mind: “Ketjap” means all kinds of thick sauces, and “catsup” was also used by antique English recipe books to mean a thick sauce made out of any fruit or vegetable.

I like the sound of “ketchup,” and I like knowing I’m using a word precisely—and that I’m now going to treat fairly all the great thickened, spicy sauces that may or may not have tomatoes in them! I always hated the sound of “catsup” anyway. It never felt right in my mouth or to my ear. “Cat’s up . . .” Yuk. “Ketchup!” Yeah!

### Which Herbs/Spices for Which Foods?

Lillian Reed, Kirkland, WA, typed the 685,000 words from the eighth edition of this book, plus addenda, onto computer disks for me so I’d have an easier time revising and expanding it for this ninth edition. As she neared the end of half a year of hard work, I invited her to add something she had created herself to the book—something that would help people. She brought me this!

APPLESAUCE: anise, cloves (ground)

ARTICHOKE: chervil, coriander seeds, fennel seeds, oregano

ASPIC: allspice
AVOCADO: ginger (fresh or ground)
BEAN SPROUTS: ginger (fresh or ground)
BEANS: mint, oregano, thyme; or 1 part each parsley, savory, and onion
BEANS, GREEN: chervil, dill seeds, dill weed
BEEF: allspice, marjoram, oregano, thyme, turmeric; or 1 part each basil, savory, and thyme
BEEF, BOILED: dill seeds
BEEF, CURRIED: saffron (threads or powder)
BEETS: allspice, anise, dill seeds, dill weed
BOUILLON, COURT: allspice, anise, bay leaf, chervil, coriander seeds, dill seeds, fennel seeds
BREAD: anise, cumin (ground or seeds), fennel seeds, saffron (powder)
BREAD, SPICE: cardamom (ground), ginger (ground)
BROCCOLI: nutmeg
BUTTER, HERB: marjoram
CABBAGE: dill seeds
CABBAGE, RED: allspice
CAKE: cinnamon (ground), mace, nutmeg, saffron (powder)
CAKE, SPICE: allspice, anise, cloves (ground)
CANDY: anise
CARROTS: allspice, anise, bay leaf, cumin (ground or seeds), ginger (fresh or ground), mace, marjoram, mint, nutmeg, tarragon
CAULIFLOWER: nutmeg
CHEESE: mint
CHEESE, COTTAGE: dill weed, thyme
CHEESE, CREAM: sage, thyme
CHEESE, GOAT: rosemary
CHICKEN: chervil, cilantro (fresh coriander), dill weed, ginger (fresh or ground), marjoram, nutmeg, oregano, rosemary, thyme; or 1 part each marjoram, parsley, savory, and tarragon
CHICKEN, CURRIED: cloves (ground), saffron (threads or powder)
CHICKEN, FRICASSEED: dill weed
CHICKEN SOUP: nutmeg, rosemary, tarragon
CHILI: cumin (ground or seeds)
CHOWDER: rosemary
CHOWDER, CLAM: marjoram, caraway seed, sage, thyme
CHOWDER, FISH: bay leaf, curry powder, dill, thyme
COLESLAW: chervil, dill seeds, dill weed, tarragon, thyme
FRIED POTATOES: anise, basil, coriander seeds, cumin (ground or seeds), garlic, ginger (fresh or ground), marjoram, oregano, pepper, sage
FRIED POTATOES, VEGETABLE: basil, chervil, coriander seeds, cumin (ground or seeds), garlic, ginger (fresh or ground), marjoram, oregano, pepper, sage
FRITTERS: cinnamon (ground)
FRITTERS, VEGETABLE: sage
FRUIT, COOKED: nutmeg
FRUIT, FRESH: ginger (fresh or ground)
FRUITCAKE: cloves (ground)
GAME: bay leaf
GINGERBREAD: cardamom (ground), cinnamon (ground), coriander, ginger (ground)
GUMBO: bay leaf, filé, thyme
HAM: cardamom (ground), cinnamon (ground), ginger (fresh or ground)
HORSEMEAT: allspice, basil, cinnamon (ground), cloves (ground), marjoram, nutmeg, oregano, rosemary, saffron (threads or powder), tarragon, thyme
LAMB: allspice, basil, cinnamon (ground), cloves (ground), marjoram, nutmeg, oregano, rosemary, saffron (threads or powder), tarragon, thyme. Or lamb seasoning 1: Combine ¼ c. dried onion flakes, 1 T. each ground cumin seed, garlic powder, pepper, and basil. Or lamb seasoning 2: Combine 1 t. each marjoram, parsley, rosemary, and thyme.
LAMB, CURRIED: turmeric
LAMB, ROAST: coriander seeds
LEEKS: chervil, sage, tarragon
LENTILS: cilantro (fresh coriander)
LIVER: basil, sage
MACKEREL: fennel seeds
MARINADE: allspice, bay leaf, ginger (fresh or ground), nutmeg, oregano, rosemary
MARINADE, GAME: coriander seeds
MARINADE, MEAT: cumin (ground or seeds)
MARINADE, PORK: fennel seeds
MEATBALLS: cardamom (ground), coriander seeds, fennel seeds
MEATLOAF: cardamom (ground), cinnamon (ground), cloves (ground), marjoram, nutmeg, oregano, thyme
MEATS, VARIETY: tarragon
MEXICAN DISHES: cilantro (fresh coriander) as topping
MINESTRONE: marjoram
MUSHROOMS: coriander seeds, oregano, rosemary, tarragon, thyme
MUSHROOMS, MARINATED: fennel seeds, marjoram
MUSHROOM SOUP: curry, oregano, marjoram
OMELET: marjoram, oregano
ONIONS: basil, sage
ORIENTAL DISHES: ginger (fresh or ground)
PAELLA: saffron (threads or powder)
PASTA: basil, cilantro (fresh coriander)
PATE: bay leaf, cinnamon (ground), tarragon, thyme
PEAS: chervil, mint, rosemary, sage
PEPPERS, HOT: cilantro (fresh coriander)
PEPPERS, SWEET: cilantro (fresh coriander)
PICKLES, DILL: dill seeds
PIE: cinnamon (ground)
PIE, APPLE: cardamom (ground), coriander
PIE, FRUIT: allspice
PIE, MCCREMEAT: ginger (ground)
PIE, PUMPKIN: cardamom (ground), cloves (ground), coriander, ginger (ground), nutmeg
PILAF: turmeric
PORK: allspice, basil, chervil, cinnamon (ground), cloves (ground), marjoram, oregano, rosemary, sage, tarragon, thyme, turmeric; or 1 part each basil, sage, and savory
PORK, CURRIED: saffron (threads or powder)
POTATOES: basil, bay leaf, chervil, nutmeg, oregano, rosemary, tarragon, thyme; or 1 t. each oregano, thyme, pepper, and rosemary
POTATOES, BOILED: dill weed
POTATOES, SWEET: cardamom (ground), mint
POULTRY: basil, sage, tarragon
POULTRY, CURRIED: cardamom (ground)
PUDDING, RICE: cinnamon (ground)
QUICHE: nutmeg
RABBIT: chervil, marjoram, rosemary, tarragon
RICE: cardamom (ground), cilantro (fresh coriander), ginger (fresh or ground)
RISOTTO: saffron (threads or powder)
ROLLS: cardamom (ground)
SALAD, AVOCADO: cilantro (fresh coriander), dill weed
SALAD, BEET: chervil
SALAD, CARROT: cinnamon (ground)
SALAD, CELERY ROOT: turmeric
SALAD, CHICKEN: basil, tarragon, thyme
SALAD, CUCUMBER: thyme
SALAD, EG: cilantro (fresh coriander)
SALAD, FRUIT: basil, cardamom (ground), cinnamon (ground), cloves (ground), mace, mint
SALAD, GREEN: chervil, marjoram, mint, tarragon
SALAD, GREEN PEPPER: cumin (ground or seeds)
SALAD, POTATO: dill weed, fennel seeds
SALAD, SEAFOOD: oregano, tarragon
SALAD, SHELLFISH: fennel seeds
SALAD, TOMATO: basil, cumin (ground or seeds), thyme
SALAD, WALDORF: mint
SALMON: fennel seeds
SALMON, SMOKED: dill weed
SAUCE, CREAM: chervil
SAUERKRAUT: dill seeds
SAUSAGE: allspice, coriander seeds, cumin (ground or seeds), fennel seeds, marjoram, nutmeg, thyme
SEAFOOD, BROILED: tarragon
SHELLFISH: basil, dill weed, mint (garnish), turmeric
SHRIMP: allspice, ginger (fresh or ground)
SOUFFLE: chervil, nutmeg
SOUP: cilantro (fresh coriander) as topping
SOUP, TOMATO: tarragon
SPINACH: nutmeg
SPREAD: basil, cloves (ground), cumin (ground or seeds), thyme
SPREAD, CHEESE: chervil, tarragon
SQUASH: cardamom (ground)
STEAK: rosemary
STEW: chervil, cilantro (fresh coriander)
STEW, BEEF: cumin (ground or seeds)
STEW, CHICKEN: cinnamon (ground), cumin (ground or seeds)
STEW, FISH: coriander seeds
STEW, LAMB: bay leaf, dill weed, fennel seeds, mint, turmeric
STEW, PORK: dill weed
STEW, RABBIT: fennel seeds
STEW, SEAFOOD: saffron (threads or powder)
STEW, VEAL: bay leaf
STUFFING: allspice, chervil, cloves (ground), dill seeds, dill weed, ginger (fresh or ground), marjoram, mint, nutmeg, oregano, sage, thyme
TOMATO JUICE: 1/4 t. dried basil per cup
TOMATO SAUCE: basil, oregano
TOMATOES: allspice, basil, bay leaf, chervil, cilantro (fresh coriander), dill weed, oregano, sage, tarragon, thyme
TOMATOES, STEWED: oregano
TURNIPS: dill seeds
VEAL: allspice, basil, chervil, nutmeg, oregano, rosemary, sage, tarragon, thyme
VEGETABLES, CURRIED: cumin (ground or seeds)
VEGETABLES, MARINATED: coriander seeds, oregano
VENISON: chervil, rosemary
ZUCCHINI: marjoram, mint, oregano, thyme

**ALFALFA to YUCCA—GARDEN to TABLE**

Mail-order sources for various herbs and spices are listed in specific entries. Look for the addresses of those firms in the source list at the beginning of this chapter. If they’re not listed, look in the source lists in Chapter 2 (for firms that also carry vegetables) or Chapter 6 (for those that specialize in trees and fruits).

**ALFALFA:** This plant makes wonderful high-protein hay for winter feed for herbivores. Also, a tea can be made from the leaves or seeds. Sometimes it is combined with peppermint. Harvest your leaves when the plant is in early bloom. Separate out the stems and discard them. Cure in the shade. Pour boiling water over the dried alfalfa to make tea. You can also eat the young tips as greens.

Violet Stewart wrote me, “I go out in a field of fresh alfalfa where there is new growth. Cut an armload and bring home. Put into a tub and wash thoroughly. Shake water out and lay on trays to sun-dry. When dampness is gone I strip tender leaves off and lay the leaves on trays and dry in
Aloe Vera: This one of the most highly regarded medicinal plants. Of the several Aloe species, the one you want is Aloe barbadensis, or Medicine Aloe. You can buy one from a florist or get a starter plant from a neighbor. Or order by mail from a source such as Merry Gardens. To use, snap off the tip of one of its fat, cactus-type leaves (they are smooth with no stickers at all). Squeeze out the natural salve from inside the leaf onto your burn, scrape, rash, or other skin problem. It's also good for sunburns. The plant will heal its broken tip and refill for the next time you need it.

**Ambrosia:** See “Epazote.”

**Angelica (Angelica Archangelica):** A hardy biennial with lush, 2–3-foot leaves when mature, angelica can get up to 8 feet tall—the largest herb that isn't a tree. Much like celery in its growing requirements, angelica does best in rich soil kept constantly moist and partially shaded.

**Planting.** Let the seeds mature on the plant; in August, gather and lay them in a flat or seedbed, uncovered by soil. (Seeds are viable for up to a year, but are best used right away.) Or just let the falling seeds self-sow and transplant. Young angelica plants grow slowly their first year, developing only a small leaf rosette. But in the second or third year, the plant begins growing rapidly. Consistently removing buds before the early spring flowers open—or at least before seed develops—turns your biennial into a perennial.

**Seeds available from Le Jardin du Gourmet, Nichols, DeGiorgi, and Thompson & Morgan.**

**Using.** Use angelica root and leaves to flavor stewed fruit. They are a natural licorice-flavored sweetener for tart fruits.

**Candied or “Crystallized” Angelica** To make this Victorian delight, which can be used in fruitcake or as a decoration or confection: Cut young, tender stems (harvest only the topmost section for this purpose) into 2–5-inch sections. Using only a little water and a covered non-aluminum pan, boil to tenderness. Pour off the water, but save it. Peel off the tough outside layer of the stems. Return to the pan with the same water and cook over very low heat until stems are green. Drain once more. When the stems are dry, put them on a kitchen scale and weigh them. Then scatter them over a baking or drying tray or a sizable plate, and scatter over them an amount of sugar equal to the weight of the herb. Let them sit in a loosely covered container in the refrigerator or a cool room for 2 days. You want them to dry, but not harden.

**After 2 days, the mass will have toughened considerably and you'll have to scrape with a knife to get it off the plate and back into the pan. Add just a few teaspoons of water so it won't burn, and heat that just to a boil. Remove the stems and drain the liquid. When the stems have cooled, return them to the pan and pour over them a newly made syrup (1 c. water to 1 c. sugar), enough to completely cover. Simmer 10 minutes. Drain off most, but not all, of the liquid. Spread the stems on waxed paper on a drying tray, and let dry until they are no longer damp to the touch.

**Anise Seed:** There are 2 different, easily confused anise spices—anise seed (see below) and star anise. Anise seed grows on Pimpinella anisum (Umbelliferae), a native of the Mediterranean area and a favorite herb of Italian cooks. An annual, it is a relative of parsley that looks like dill, grows 18–24 inches tall, and bears decorative yellow flowers. The plant parts have a mild, sweet licorice flavor. Anise doesn't require fertilizing, weeding, or full sun. Available from William Dam, DeGiorgi, etc.

**Growing.** Anise is naturally a warm-climate plant; it needs at least a 120-day season to grow and produce seed. If you live in a cold, northern region, start seeds indoors in the fall.
in very moist soil in a fiber pot. Next spring, after the last frost, plant the whole pot in full sun, because anise doesn't transplant well. Or plant directly to garden, or just keep it in a container. Space plants 18 inches apart. You can save your own seed; it remains viable for 3–4 years.

**Harvesting.** Gather leaves while still young and tender. For your seed harvest, cut the plants off at ground level in August, when the seeds are fully formed and are drying on the plant. Dry the plants and store them inside a big paper bag (seed heads down) in a warm, dry place for further drying—or dry in oven or dehydrator at 110°F. Then loosen seeds, separate from chaff, and store in tightly closed jar.

**Using.** Anise leaves can be chopped and added to a salad or to fish dishes. Use seeds in cakes, cookies, and other sweet dishes, in curry mixtures, and in Italian anise toast. Anise root is also edible; it can be chewed on or candied in very thin slices, like ginger. Oil of anise is used in commercial cough medicines. Anise tea is a valid home remedy for asthma, bronchitis, cough, and congestion.

**ARUGULA:** See “Rocket” in Chapter 4.

**Balm, Bee (Monarda didyma):** This North American hardy perennial herb (a New York native) is called bee balm because its splendiferous scarlet or pink flowers are strongly attractive to bees. (Hummingbirds like them too.) It's also called bergamot, Oswego tea, and Monarda. It is bush-shaped and grows up to 4 feet tall.

**Planting.** Bee balm is best started by root division in the spring or fall. Plant in fertile, moist soil. It tends to spread, but not invasively. Keep it under control and divide it at least every 3 years.

Growing bee balm from seeds is difficult. Try planting seeds in the spring or fall; growth will be very slow. Seeds remain viable 2–3 years and are available from Harris and Hudson.

**Using.** The heavily aromatic, lemony leaf is edible and makes a good tea (so used by the Oswego Indians). It's also good in fruit punches, fruit soups, and potpourri. Leaves picked right before flowering are the most scented, but they can be picked and dried anytime during summer. Good in poultry stuffing.

**Bee Balm Fancy Tea** Combine 1 part each dried bee balm leaves, dried basil (or sage), and dried citrus peel.

**Balm, Lemon (Melissa officinalis):** Also called sweet balm, lemon balm is another hardy perennial herb bush; it grows 2–3 feet tall and has little white flowers and lemony-mint–flavored leaves. There are several varieties. Seeds available from Hudson, Nichols, Redwood City, DeGiorgi, etc.

**Planting.** Lemon balm starts nicely from seed and will spread by seed drop in your garden as well as by runners. You can also propagate it by planting cuttings and root divisions. It will grow well in northern as well as southern zones, but plant in damp, fertile soil. It actually prefers partial shade, so plant near a tree or fence.

**Harvesting.** For preserving, pick whole stems just before the plant flowers. Dry quickly and package in an airtight container. For fresh use, just go out and pick leaves. Always use or preserve balm without delay; the flavor and scent quickly disappear into the air.

**Using.** Its leaves are so strongly flavored that they will give a lemony touch to any dish, and you can substitute fresh or dried balm for lemon in any recipe. Use fresh leaves in salads. Leaves are used commercially in perfumes and toilet waters and to flavor Benedictine. Balm makes great herb tea and is famous as a headache relief. Serve as an iced tea in summer and hot tea in winter. Balm is also good for scenting your soap. Fresh balm is best for cooking; dried leaves are good in potpourri or sachets for linen storage, being somewhat insect-repellent.

**Chinese 5-spice Blend** In a blender or mortar combine 2 T. black peppercorns, about 40 whole cloves, 10 inches cinnamon stick, 2 T. fennel seed, and a dozen star anise. Blend or grind together. Store in an airtight container. Good in Chinese recipes and any chicken dish.

**Artemisia:** In my childhood I knew it as plain old sagebrush. It was my favorite plant. I loved the silver-gray leaves and their pungent sage scent. Sagebrush is not a true sage, but is actually in the sunflower family. Native Americans used to dry and burn the sagebrush leaves as a sacred incense. You can order big sage, Artemisia tridentata, and prairie sage, Artemisia ludoviciana, from Redwood City. (See also “Southernwood” and “Wormwood”; these are related sage species.)

**Arugula:** See “Rocket” in Chapter 4.

**Balm, Bee (Monarda didyma):** This North American hardy perennial herb (a New York native) is called bee balm because its splendiferous scarlet or pink flowers are strongly attractive to bees. (Hummingbirds like them too.) It's also called bergamot, Oswego tea, and Monarda. It is bush-shaped and grows up to 4 feet tall.

**Planting.** Bee balm is best started by root division in the spring or fall. Plant in fertile, moist soil. It tends to spread, but not invasively. Keep it under control and divide it at least every 3 years.

Growing bee balm from seeds is difficult. Try planting seeds in the spring or fall; growth will be very slow. Seeds remain viable 2–3 years and are available from Harris and Hudson.

**Using.** The heavily aromatic, lemony leaf is edible and makes a good tea (so used by the Oswego Indians). It's also good in fruit punches, fruit soups, and potpourri. Leaves picked right before flowering are the most scented, but they can be picked and dried anytime during summer. Good in poultry stuffing.

**Bee Balm Fancy Tea** Combine 1 part each dried bee balm leaves, dried basil (or sage), and dried citrus peel.

**Balm, Lemon (Melissa officinalis):** Also called sweet balm, lemon balm is another hardy perennial herb bush; it grows 2–3 feet tall and has little white flowers and
Using. Dried basil is weaker and different than fresh or frozen, but is still useful. Make a medicinal tea; flavor vinegar, tomato dishes, eggs, fish, cheese, soups, stews, meat pies, lamb chops, squash, peas, green beans, or salad dressing. Or use in potpourri—or pesto...

PESTO: In your blender, mix 4 cloves garlic, 2 c. freshly picked basil, 1/4 c. nuts (pine nuts or walnuts are good), 1 t. salt, 1/4 t. pepper, and 1/4 c. olive oil. As you blend, gradually add another 1/4 c. olive oil. Pour into a bowl. Stir in 3 oz.just-grated Parmesan or other firm cheese. Use pesto right away. If you must keep it, store in an airtight container (air exposure makes pesto turn brown). Pesto is great as a sauce for noodles or green beans, or as a flavoring for pasta, soups, or cooked fish. To freeze pesto, omit cheese, adding only when thawed and ready to serve.

BAY: There are 2 varieties, sweet bay and California bay. Both are warm-climate plants, although sweet bay is harder than California bay, which is subtropical (zones 8-10). Both are evergreen trees. Both can be grown either in sun or semi-shade. If you live in the desert, you'll need to water them once in a while. Keep the soil well drained, and let it dry out between waterings.

Sweet Bay. Sweet bay is the seasoning leaf you find in the stores. Also known as bay laurel (Laurus nobilis) and Grecian laurel, it grows 25-40 feet high. It can be clipped into almost any shape you want and thus severely limited in size, and it does well in containers. It's your best choice if you're in a northern climate (bring it inside for the winter). In a container, bay needs a coolish room; repot it once a year or when leaves are 2 inches long. Plants available from Comstock, DeGiorgi, William Dam, Hudson, and Park. But I don't recommend burnet because it's not that important as an herb, and is so likely to become a weedy nuisance in your garden.

California Bay (Umbellularia californica). Also known as California laurel, Oregon myrtle, and pepperwood, this bay grows wild on the California coast and in southwestern Oregon. It can get much taller than sweet bay—up to 75 feet high and 100 feet wide—but it's planted only from seeds and grows slowly, so you're not likely to see that size outside of the forest. It is naturally multi-stemmed and drought-resistant. Fruits are inedible. Plants available from Pacific Tree Farms and Raintree Nursery.

Using. The flavor of the California bay leaf is similar to that of the sweet bay but is significantly stronger. Both are used to perk up soups, stews, and meats. Both can be gathered any time of year, but late summer is preferable. Choose small but mature leaves. The leaves should not be crumpled; handle them carefully. Discard any broken ones. Dry outside away from direct sunlight, turning once, until brittle. Or dry in oven or dehydrator at 110°F Store in airtight jar. Add 1, 2, or 3 whole leaves at the beginning of the cooking process to any dish you want to flavor: stews, soups, spaghetti sauce, any meat or fish dish. Do not eat the leaf itself; remove it before serving, or warn the unknowing to discard it if found in their portion. A wreath for the head made of sweet bay leaves was a Roman award of honor.

BEE BALM: See “Balm, Bee.”

BERGAMOT: See “Balm, Bee.” The bergamot oil used by the perfume industry is extracted from the Italian bergamot orange.

BORAGO (BORAGO OFFICINALIS): This is an easy-to-grow, ornamental and edible annual herb with hairy cucumber-flavored leaves and numerous lovely bee-attracting, intensely blue flowers. Grows up to 2 feet tall—more in heavily manured soil. Does well in a container, and can handle partial shade.

Planting. Plant seeds in spring, early summer, or fall. Plant several seeds per spot, and then thin to 1 plant. Plant in succession to keep prime plants available. Doesn't like wet feet. Once established, it will self-sow and create a dense clump, so allow room for that when planting. It grows quickly whether in a bed, row, or pot; it's nice to have indoors in winter. Available from Thompson & Morgan, William Dam, Redwood City, DeGiorgi, etc.

Harvesting and Using. Both flowers and leaves can be eaten. In general, preserve and use like basil. Leaves will be ready in about 6 weeks. They're best harvested before flowers appear—while the leaves are still young, tender, not too hairy, and about 2 1/2-5 inches long. Mince them fine and add to an early spring salad or to cool drinks. Or cook like spinach (the hairs will cook away) or add to soup. Flowers are best harvested when they are just opening. Add them to salads and lemonade.

BORAGE TEA: Soak a handful of borage leaves in water that has been boiling. Then chill, sweeten to taste, and add ice. Serve with a borage flower floating atop!

CANDIED BORAGE FLOWERS: You can actually do this to any tiny flower. Dip the flower in egg white and then into sugar. Dry and use plain or as cake decorations.

BURNET (POTERIUM SANGUISORBA OR SANGUISORBA MINOR): This herb perennial with cucumber-flavored leaves and lovely flowers is also known as salad burnet. A wild variety called great burnet (Sanguisorba officinalis) can be used in the same way as salad burnet.

Planting. This very hardy plant is a creeper, easily grown from seed or by root division in early spring. Seeds or plants are available from Comstock, DeGiorgi, William Dam, Hudson, and Park. But I don't recommend burnet because it's not that important as an herb, and is so likely to become a weedy nuisance in your garden.

Harvesting. Burnet doesn't dry well, but it can be picked off the plant even in winter, so that doesn't matter. Pick center leaves; older, outer ones are tough and taste unpleasant. Leaves (only!) are used in salads, as garnish, as flavoring for vinegar, in any cream soup, as a sandwich topping (minced and mixed with butter), or as a tea.

CALENDULA: See “Marigold, Pot.”

CAMOMILE: See “Chamomile.”

CAPERS: Capparis spinosa originates in the Mediterranean area of Europe. The plant is grown for the unopened flower buds, or capers, which can only be eaten pickled but are considered a delicacy. They grow 3-5 feet tall. (Nasturtium is used similarly but is not the real thing.)

Planting. Plant seeds or cuttings in full sun. The plant is easy to grow if you have a dry, mild climate. It thrives in sandy or rocky ground, relatively poor soil, and on hillsides—in a sunny, warm, well-drained site. It will be an evergreen perennial in the warmest zones (9-10), but will winterkill in zones 6-8. Grow it there as an annual, starting indoors if your summer is on the short side. Seeds available from Park and Pacific Tree Farms.
Harvesting. In summer, harvest the flower buds just before they open. They will look small and green. Keep them in the dark 3 hours; then pickle them. The fruit of the caraper is also edible and can be pickled.

**PICKLING CAPERS** Have ready clean, hot pint (3) or cup (6) canning jars. Divide 1 qt. washed capers between the jars. In a stainless steel or enamel pan, mix together ½ c. brown sugar, ½ c. water, 1½ c. wine vinegar, 1 crushed clove of garlic, and 1 t. each mustard seed, salt, dill, and celery seed; if you wish, add mace, green onions, garlic, nutmeg, or peppercorns. Boil the pickling solution hard for 10 minutes. Pour it through a strainer to get out the solids and then boil once more. Pour the almost-boiling liquid over the capers. Pack in ½-pint jars. Process in boiling-water bath 15 minutes. Keep in a cool, dark place and wait at least 10 days before using to allow capers to pickle. Use pickled capers in soups, stews, vegetable dishes, salads, sauces, fancy sandwiches, and poultry stuffing. (See “Nasturtium” for more recipes.)

**CARAWAY** (CARUM CARVI): This plant comes in 2 varieties. The old-timer is a biennial: You plant it one year, and it grows that first year and makes seed the next. Now there's an annual kind too.

**Planting.** Plant 8 inches apart in the spring (or fall) in a well drained, sunny place where you can leave it for 2 years, such as the border of your garden. Mulch roots in the fall to avoid freezing. It grows about 2½ feet tall. Once you've got it, it tends to self-sow. Caraway seed is viable for 2 years and is available from DeGiorgi.

**Harvesting.** When seed clusters ripen the second year (turning brown), cut off flower heads. Dry away from direct sun in a warm, dry place, laying flat on screen, paper, cloth—a surface from which you can easily gather spilled seeds. Once the seeds are dry, finish threshing by rubbing the heads with your hands. Blow off chaff and store seeds for planting or eating.

**Using.** The seeds make good additions to rye bread, biscuits, sauerkraut, and cottage cheese. Or cook them with cabbage and cauliflower. The flavor of caraway stems and foliage is similar to the seeds but milder. Use them in cheese and fish recipes and salads.

**CARAWAY-STUFFED CELERY** Mix cream cheese with caraway seed and stuff into hollow side of celery. Cut into 2-inch sections. Sprinkle with paprika.

**CARDAMOM** (ALSO CARDAMON): *Elettaria cardamomum*, whose seed is an aromatic spice, is a relative of ginger and a native of India. It grows on a shrubby little tree, 8–10 feet high, also known as the cinnamon palm. You can grow it in a temperate-zone garden if you move it to a pot and bring it into the house before winter. The leaves are deep green with a spicy ginger-like scent. It bears fruit only when 3 years old.

**Planting.** Cardamom is propagated 2 ways, by seed and by transplanting the plant just after harvest. That causes the top part to die, but the roots send up a new one—which fruits after 2 years. Available from Merry Gardens.

**Harvesting.** Pick it whole (seeds inside their pods) and grind before using, pods and all. The pods will disintegrate as a result of the cooking but will enrich the flavor. Also use pod and all in pickling mixes. Use ground to flavor puddings, pies, ice cream, and Danish pastries.
Roman/Garden/True Chamomile (Chamaemelum nobile, a.k.a. Anthemis nobilis). This small evergreen perennial is grown either from seed or by root division. It makes a good ground cover and can survive in partial shade and without fertilizer. Available from Redwood City and Thompson & Morgan.

Sweet False Chamomile (Matricaria recutita). This 2–2½-foot-tall annual is propagated only by seed. Plant 1 foot apart in full sun and well-drained, light soil. It germinates easily, self-sows, and has pineapple-flavored flowers. Available from DeGiorgi.

Harvesting, Preserving, and Using. The little daisylke flower heads are the usable parts of both types of chamomile. Gather when in full bloom and dry at 110°F. True chamomile is the best for medicinal and tea use.

CHAMOMILE TEA Pour 1 pint boiling water over 3 t. dry flowers and steep to make tea. It’s bitter medicine; Peter Rabbit had some when he got back home. It’s supposed to be good for indigestion, chills, and nervousness, and he had all three. It’s also used as a rinse for blonde hair and as a treatment for plant diseases.

CHERVIL (Anthriscus cerefolium): This hardy annual grows 1½–2 feet tall. Delicate and ferny in appearance, it is easy to grow and does well in poor soil as long there is water. The 2 basic varieties are “curled” and “flat.”

Planting. Chervil does best shaded from hot afternoon sun. Plant in spring or late fall in the garden; it doesn’t transplant well. Don’t cover the seed; it requires light to germinate. Plant every few weeks thereafter until midsummer to keep it coming prime. Available from William Dam, Thompson & Morgan, Redwood City, DeGiorgi, etc.

Harvesting. For freezing, use tender young leaves cut from seedlings at least 6 weeks old. You can use older leaves for drying (at 110°F until brittle). Cutting off seedheads promotes leaf growth. If you allow the plants to flower, they will self-sow but basically stay in the same area.

Using. Chervil is the gourmet’s parsley. Use it fresh as you would parsley, as a garnish and in salads, especially when you want a milder flavor than parsley. Use frozen or dried in soups, salads, poultry, fish, and egg dishes. Its flavor is mild; use 1 T. dried herb for salad, 2–3 T. for cooked dishes.

CHERVIL VINEGAR It’s good in salad dressings. Half-fill a bottle with fresh or dry leaves. Fill the bottle with good vinegar, and heat it gently by placing in warm water. Bring water to boiling point. Remove from heat; when cool, cap. Let steep 2 weeks. Then it’s ready.

HERB SOUP Seasoned with chervil, this can be varied indefinitely as to the green vegetables. For a start, pick sorrel, spinach, and lettuce fresh from your garden, and get rid of any tough midribs. Wash and shred. Use 1 c. finely shredded spinach, ½ c. shredded sorrel, and ½ c. of the white heart leaves of head lettuce. Use about ¼ c. butter and saute (don’t brown). Add 4 peeled potatoes, 1 T. salt, and 2 qt. boiling water. Let the soup simmer gently for 1 hour. Crush the potatoes, add 1 T. chervil, and simmer 5 minutes more. Add a cup of croutons before serving.

SOUR CREAM AND HERB DRESSING Mix this in a jar and serve on green salads as you need it. Mix 2 c. sour cream and 1 t. each chopped parsley, chives, tarragon, and chervil. Add 2 T. brown sugar, ¼ c. vinegar, ½ c. oil, a grind of pepper, a dash of salt, and 1 t. dry mustard. Mix well.

CHICORY: See “Coffees that Aren’t Coffee” under “Cocoa, Coffee(s), and Tea” in this chapter, and “Leaf Vegetables” in Chapter 4.

CHILIES: See “Peppers, Hot” in Chapter 4.

CHINESE PARSLEY: See “Coriander.”

CHIVES: See “Allium” in Chapter 4.

CILANTRO: See “Coriander.”

CINNAMON: This is the bark of a tropical evergreen bush (Cinnamomum zeylanicum) that only grows in India and Sri Lanka. There are several other varieties of cinnamon tree. Cassia cinnamon (see “Cassia”) and Ceylon cinnamon are most common. The tree is hardy down to only 30°F. The bark can be burned as incense, turned into scented bath oil, and used to season food. Available from Pacific Tree Farms. For detailed instructions on harvesting cinnamon, see the herbal section of Rodale’s Encyclopedia of Organic Gardening.

MAKING COARSELY CRUSHED CINNAMON Break sticks into pieces, put them into a bag, and pound with a hammer.

CINNAMON SUGAR Combine ¼ c. sugar with ½ t. ground cinnamon. Mix well and store in a covered jar. Use on toast, etc.

CLARY SAGE: See “Sage, Clary.”

CLOVER: This is wonderful stuff. All the varieties of clover are legumes, can be planted for a green manure crop, and should be inoculated. There are other fun things you can do with the clover blossoms! Redwood City offers Trifolium pratense, a red clover variety whose dried blossoms make a sedative tea and whose seeds make good salad sprouts.

ALASKA HONEY Larry Malcom wrote me from Eagle River, AK, to supply this recipe “for people who for reasons cannot have bees but still want to make honey! Boil together 10 c. sugar and 2 c. water for 10 minutes. Remove from heat and add 1 t. alum and 25 fireweed flowers, 45 pink clover flowers, 45 white clover flowers (or 90 clover of any color). Let stand 5 minutes. Strain and pour into jars. Simple, isn’t it? And it comes out nice and thick and wonderfully good! We’re having a taffy pull this weekend. Hooray! Went dog-sledding yesterday for the first time. Beats sno-machines hands-down! So quiet, with a full moon!”
CLOVER BLOOM VINEGAR: Combine 6 lb. brown sugar, 1/2 bushel clover bloom, 4 qt. molasses, and 9 gal. boiling water. Let cool. Add 3 T. dry yeast dissolved in 1/4 c. water. Let stand 14 days, strain, and store until it tastes like vinegar.

CLOVES: These are actually the unopened flower buds of an evergreen tree. The tree grows wild in the Molucca islands, the West Indies, Sumatra, and Brazil. To harvest, gather the purplish buds (growing on those familiar little clove stalks) before they open. Dry. The drying will turn them from reddish to dark brown. Use whole or ground. Powdered cloves can be used as a louse or flea powder on small animals.

COMFREY: Comfrey is controversial. It used to be considered totally harmless, a traditional cure for anything, food for anything. Well, it’s not deadly poison, but modern chemistry has identified a poisonous substance in it, pyrolizidine, so the up-to-date recommendation has to be that it should not be eaten in any form.

Too bad, because this is a deep-rooting, hardy perennial with lush green leaves that can grow 3 feet high and come back quickly after being cut back. (The same hardiness has been known to result in a comfrey-turned-weed problem.) Symphytum officinale is widely available. Russian comfrey (Symphytum peregrinum) is slow-growing, is a source of compost material for organic gardeners, and is used to feed animals. Comfrey cannot be raised from seed. It has to be propagated by root cuttings. Plant a 2-inch root cutting 4 inches deep any time of the year—3 feet apart, in full sun or partial shade. (Don’t transplant.) Keep seedbed moist until germination. It grows 2-4 feet tall. Let the seed pods dry. Do this when some seed pods have ripened (around 2 months after you planted). Don’t wait for all the pods to ripen, or you’ll go out there one day and find the pods shattered and seed scattered on the ground. Proceed as you would for caraway. Mash seeds with a rolling pin. Put in apple pie and apple butter, also see “Curry Powders” under “Food Seasonings” for recipes.

Using. Some people hate cilantro’s smell. Strange but true: When cooked, the flavor of the plant will be milder and more pleasant than its odor in your garden. Use the pungent leaves to flavor salsa verde, guacamole, soups, stews, salads, stir-fries, egg, fish, pork, hot dogs, etc. It’s great with anything tomatoey and is used in Mexican and Indian cooking and in pickling mixes. Just don’t use too much!

CILANTRO CHICKEN TOMATO SOUP: Shelley Dalen, Pasco, WA, sent me this. “My husband’s grandmother gave it to him. It’s quick, easy, one-pot, cheap, delicious, and can be changed around. It also can use lots of tomatoes when your garden is going nuts. Turn your burner on medium. Put a cut-up fryer, or just chicken pieces, in a Dutch oven (on the burner). Cover the chicken about 3 inches deep with tomatoes (canned or sauce is OK but fresh is best). Use more if you want more broth. Stir once to get a few tomatoes under the chicken and to prevent the chicken from sticking to the bottom of the pan. Put 1 large peeled and chopped onion on top of the tomatoes. Put 1/2 c. snipped fresh cilantro (or any other fresh or dried herb you like, in the amount you like) on top of the onion. Cover tightly, and let cook for 30 minutes. I serve with corn tortillas.”

CRESS: Pepper grass is the most peppery of the cresses and the easiest to grow, given its ability to tolerate more dryness and heat than the others. It grows fast to 4-5 inches high. Another variety of seasoning cress is Upland, also with peppery-tasting leaves. Add chopped cress to a green salad or potato salad, or sprinkle over sliced tomatoes with a dash of vinegar/oil dressing. Cress is a good winter pot plant too. Available from DeGiorgi.

CUMIN (Cuminum cyminum): This annual plant, an ancient Mediterranean herb, resembles fennel. It blooms with pink and white flowers and is raised for its seeds.

Planting. Plan for the 16 weeks of growth necessary to mature seed. So if you live in the northern United States, start indoors and transplant only after the soil is warm. Plant in light soil. The seeds will grow on the flower head and by late summer, they will be too heavy for the plant to hold; instead it will sprawl over the ground. Let the seed pods dry on the plant until they are just about to burst and be scattered. Then harvest, shell, and dry. Cumin seeds are good mixed with any cheese, in bread, beans, rice, sausage, pork, or wild meat sauces. Ground cumin is used in curry, pickling, and chili powder mixes. Available from Redwood City and DeGiorgi.

DAYLILY: Originally from East Asia, the many species of Hemerocallis, the daylily, have long since become local...
Dill. They are perennials with bright flowers, sold in a multitude of named varieties; they also live in the wild. The entire plant is edible: spring shoots, summer buds, flowers, leaves, and the small tubers. Like weeds, they do well in any soil and in either sun or shade. Some varieties need occasional dividing; some need almost nothing at all. Daylilies (or seed) available from Burpee, Park, Thompson & Morgan (seed only). The best selection of all is from Gilbert H. Wild and Son, who is a daylily specialist and offers a huge number of kinds: P.O. Box 338, Sarcoxie, MO 64862, (417) 548-3514.

**Using.** Harvest young outer leaves in early spring when 3–6 inches long. Steam, saute, or stir-fry. The flower buds and blossoms are all edible. They have a sweet taste and an okra-like, mucilaginous quality. Closed buds can be pickled like capers, prepared as tempura, or cooked into omelets. To gather the little tubers, wait until fall or even winter, when they have had a chance to store food all summer. While you’re dividing too-dense clumps, you can harvest the daylily tubers. Wash, peel, and prepare like potatoes; eat raw or in a salad like Jerusalem artichokes; or prepare like salsify fritters.

**Dandelion:** See “Leaves We Eat” in Chapter 4.

**Dill (Anethum graveolens):** This common garden herb is an annual with little yellow flowers and feathery leaves.

**Planting.** Available from almost any catalog, dill doesn’t transplant, but will grow from seed (viable for 2–3 years). Plant ½-inch deep, spaced 3 inches apart, in garden in spring or fall, or in 6–8-inch pot indoors. Needs moist soil, especially before germinating. Germinates slowly. You need only a row about 1½ feet long to meet your needs. It can be interplanted with any member of the cabbage family, or cucumbers. Dill can get up to 4 feet tall but doesn’t shade its neighbors because of its fine, ferny leaves. When harvesting, leave 1 plant to self-seed; it won’t become a problem weed. For winter use, dig up little 2–3-inch plants grown from self-seeding in the fall and pot them.

**Harvesting.** If dill is allowed to dry out completely, it may flower prematurely. The leaves (dill weed) and seeds and flower heads (dill heads) are all used to flavor foods.

To harvest dill weed, cut off what you want any time after it gets 1 foot high. It’s strongest in flavor just before flowering, so you can plant some early for seed at pickling time and some late for milder “weed,” because once the plant flowers the weed isn’t as good.

To harvest dill heads, pick before the seeds have formed, and pick only the heads. Plants are likely to make a second or third crop of heads. These are nice added to each jar of dill pickles.

To harvest dill seed, cut the plants before the seed heads turn dark brown, because after that seeds begin falling. Harvest on a dry summer day. Tie in bunches and hang in an airy but shady place. Have something underneath to catch seeds that drop, or just lay them on a clean paper. When the heads are dry, shell off the seeds and store in covered glass jars, or fold up stalks and all in your paper (they’ll keep fine). One school of thought says the seed is better dried off the heads; I can’t tell the difference. You can also freeze dill or grow it in a kitchen pot through the winter. It’s amazing stuff. A friend of mine poured the brine from a jar of dill pickles on the ground by her garbage cans, and—“lo!”—a crop of dill grew there.

**Using.** Use fresh or dried. Dill weed is milder than the seed. Add it to vegetable dishes, salads (especially macaroni and potato), and soups. Heads, seeds, and stems can be used to make dill pickles or any recipes involving raw cucumbers. You can put a whole dill head in a jar of homemade pickles or dill vinegar. Dill also goes well in bread, yogurt, cheese, sour-cream vegetable dips, mashed potatoes, eggs, and mustard mixes; with fish; and with sauerkraut or cabbage in any form. Dill seed tea is a traditional treatment for adults with indigestion. A tea made from the branchlets is a traditional solace for babies with colic or gas.
**EUCALYPTUS:** This family of trees and shrubs has over 500 species in its native Australia, about 150 of which are now thriving in Arizona and California, since it is a natural for deserts. Some have leaves with odd colors, such as blue; many have beautiful flowers. Some species have lemon, peppermint, or medicinal scents. The leaves of some species are always fragrant; others must be crushed to release the scent (use their leaves in potpourris and sachets).

Eucalyptus plants are extraordinarily fast-growing, as much as 10–15 feet/year while young, and they can live a century. All species are tender, so if you have one in a planter, keep it in the house in cold weather and move it outside only for warm weather. Doesn’t transplant well; don’t change it from container to ground or back again. For more information, see the Sunset Western Garden Book.

**EUCALYPTUS COLD REMEDY** From Clara Magers, Modesto, CA: “We had eucalyptus trees out in front. My mother took some leaves and boiled them in a saucepan with some water and then let it simmer. We who had a cold would stand over the stove with a towel over our heads and breathe the steam. It clears your head.”

**FENNEL:** This herb comes in a confusing number of varieties. Chapter 4 discusses sweet fennel (stalks eaten) and finochio or Florence fennel (bulb eaten). The herbal fennel for flavoring, *Foeniculum vulgare,* is a hardy biennial. It can become a weed in your garden, hard to control. The answer to that is Bronze fennel, a less aggressive variety. Available from Redwood City.

**Fennel vs. Dill.** Fennel is different from dill in that it prefers slightly alkaline soil, but it resembles dill in growing 3–5 feet tall, with feathery branches and yellow flowers. The resemblance is familial, for the two are relatives and shouldn’t be planted close together due to the risk of cross-pollination. Plant and harvest as you would dill, but don’t interplant as you can with dill; instead, put fennel at the back of your herb garden, since it has a reputation for inhibiting vegetable growth.

**Using.** Fennel weed or seed can be substituted in any dill recipe, but it’s on the strong side, so just use a pinch or two. Fennel is also used in apple recipes and to flavor candies.

**Fennel Seed Tea.** Straight fennel tea is an old-time remedy for baby colic. For an interesting combo, try fennel-mint tea: half peppermint leaves and half fennel seed or weed.

**FILE:** See “Sassafras.”

**GERANIUM:** There are many kinds of genus *Pelargonium,* family Geraniaceae. The “scented” or “sweet-leaved” geraniums are tender perennials originating in South Africa. They have very minor flowers compared to their beautifully blooming unscented relatives. What they do offer is fragrance of every sort—you choose the variety: almond, anise, apple/nutmeg, apricot, balsam, cinnamon, clover, eucalyptus, filbert, ginger, lavender, lemon, musk, orange, peppermint, pine, rose, strawberry, southernwood, or violet. The plants vary extremely in the intensity of scent. Usually the leaves must be in the presence of the hot sun or else lightly rubbed in order to release their fragrance, but some are extremely fragrant without that help. The rose geranium (*Pelargonium graveolens*), which has a spicy rose scent, is one of the oldest and still one of the most popular kinds.

**Using.** Geranium bushes grow 1–4 feet tall: only up to a foot if grown in a pot in the north, up to 4 feet if grown outdoors in a subtropical zone. They can be grown in the garden in summer in a moderate temperate zone, but must be moved inside in a container before frost. They’re most often kept permanently in a container; they actually do better when pot-bound and will keep thus for years. Don’t move the pot outside until the sunny days of early summer. Propagate by making stem or root cuttings from new young shoots. They can be planted from seed, but since you cannot depend on the seeds to grow true to type, you’re better off starting with a plant. Plant in dry, sandy, fertile soil. Place in full sun. Keep on the dry side.

**PLANTING.** Seeds need to be chilled before planting for 3–6 weeks. Seeds available from Redwood City.

**Harvesting.** Harvest the plant when the blossoms are just starting to open. It’s a close relative of chamomile and is a traditional folk medicine for colds, fever, and flu. Combine with sage for a sore throat. Old-time feverfew was single-rather than double-flowered. A strong feverfew tea on your skin is reputed to have insect-repellent value. Feverfew has been closely studied by pharmacologic researchers, who have established that its use has no risks and that it helps prevent migraine headaches! It wouldn’t hurt to try it on a fever.

**Using.** Fennel is different from dill in that it prefers slightly alkaline soil, but it resembles dill in growing 3–5 feet tall, with feathery branches and yellow flowers. The resemblance is familial, for the two are relatives and shouldn’t be planted close together due to the risk of cross-pollination. Plant and harvest as you would dill, but don’t interplant as you can with dill; instead, put fennel at the back of your herb garden, since it has a reputation for inhibiting vegetable growth.

**Using.** Fennel weed or seed can be substituted in any dill recipe, but it’s on the strong side, so just use a pinch or two. Fennel is also used in apple recipes and to flavor candies.

**Fennel Seed Tea.** Straight fennel tea is an old-time remedy for baby colic. For an interesting combo, try fennel-mint tea: half peppermint leaves and half fennel seed or weed.

**FILE:** See “Sassafras.”

**GERANIUM:** There are many kinds of genus *Pelargonium,* family Geraniaceae. The “scented” or “sweet-leaved” geraniums are tender perennials originating in South Africa. They have very minor flowers compared to their beautifully blooming unscented relatives. What they do offer is fragrance of every sort—you choose the variety: almond, anise, apple/nutmeg, apricot, balsam, cinnamon, clover, eucalyptus, filbert, ginger, lavender, lemon, musk, orange, peppermint, pine, rose, strawberry, southernwood, or violet. The plants vary extremely in the intensity of scent. Usually the leaves must be in the presence of the hot sun or else lightly rubbed in order to release their fragrance, but some are extremely fragrant without that help. The rose geranium (*Pelargonium graveolens*), which has a spicy rose scent, is one of the oldest and still one of the most popular kinds.

**Using.** Geranium bushes grow 1–4 feet tall: only up to a foot if grown in a pot in the north, up to 4 feet if grown outdoors in a subtropical zone. They can be grown in the garden in summer in a moderate temperate zone, but must be moved inside in a container before frost. Propagate by making stem or root cuttings from new young shoots. They can be planted from seed, but since you cannot depend on the seeds to grow true to type, you’re better off starting with a plant. Plant in dry, sandy, fertile soil. Place in full sun. Keep on the dry side.
flavoring drinks. Make a tea out of the leaves, or flavor a compote or pound cake. To flavor any cake, put a leaf in the bottom of your cake pan and pour the cake batter over it. To flavor jelly, put a leaf of rose geranium in the bottom of the glass. Oil of geranium has some insecticidal value.

**GERANIUM POTPOURRI** Combine 8 c. geranium leaves, 2 c. geranium flower petals, 1 c. leaves from your choice of a fragrant mint (all pre-dried), and 1 T. each of powdered coriander seeds and powdered cardamom seeds. Use gum benzoin (1/2 oz.) or orrisroot as your fixative. From Janice Lamp, Port Orchard, WA.

**GERANIUM-ROSE POTPOURRI** Combine 3 c. rose petals, 3 c. geranium petals, 1 c. peppermint leaves, 1 c. lavender petals, 1 T. powdered nutmeg, 1 T. powdered cloves, and powdered orris or 2 oz. gum benzoin for fixative. (See “Potpourri” under “Products and Processes” for additional recipes and instructions about fixatives.)

**ROSE GERANIUM CAKE** Sift together 2 c. flour, 1/2 t. salt, and 1 t. baking powder. Cream 1/2 c. butter and 1 c. sugar. Add alternately the flour and 1/2 c. water. Finally, add the unbeaten whites of 4 eggs. Whip hard for 5 minutes. Line a loaf pan with buttered paper and rose geranium leaves. Pour in batter. Bake in a 350°F oven for 30-45 minutes. Pull the leaves off with the paper when the cake is done.

**ROSE GERANIUM JELLY** Make by flavoring apple jelly. Wash the apples, but do not peel or core. Quarter the apples and barely cover with water. Simmer until tender. Get the unbeaten whites of 4 eggs. Whip hard for 5 minutes. Line a loaf pan with buttered paper and rose geranium leaves. Pour in batter. Bake in a 350°F oven for 30-45 minutes. Pull the leaves off with the paper when the cake is done.

**GINGER (ZINGIBER OFFICINALE):** This is a tropical Asian native; it can grow outside in Puerto Rico or Florida, but north of that needs a greenhouse or comparable hot, humid room in your home to thrive. Cold wet dirt kills ginger. Ginger is grown for the root, which is not really a root but a “rhizome,” an enlarged underground stem. Ginger root is spicy. An old-time horse trading trick was to poke some ginger up the tail end of a tired old horse right before sale and return it to the stove. When almost done, put a few rose geranium leaves into the boiling jelly. They quickly give off their flavor. Dip them up and down until you have the desired taste and fragrant smell. Use 2 or 3 leaves for each pint. Tint a rose color with food coloring. Remove the leaves. Pour the jelly into your jars and seal.

**Ginger (Zingiber officinale):** This is a tropical Asian native; it can grow outside in Puerto Rico or Florida, but north of that needs a greenhouse or comparable hot, humid room in your home to thrive. Cold wet dirt kills ginger. Ginger is grown for the root, which is not really a root but a “rhizome,” an enlarged underground stem. Ginger root is spicy. An old-time horse trading trick was to poke some ginger up the tail end of a tired old horse right before sale time; it would prance around and act very young!

**Planting.** Ginger does well in a medium-sized container. Plant in well- and regularly fertilized dirt—but not sandy, pebbly, or gravelly soil. Water well and frequently. If outdoors, it needs partial shade. The stems grow 3-4 feet tall, leaves almost a foot long. Outdoor tropical plants are harvested in December and planted in February; you can actually harvest anytime after 5 months, but the longer you wait, the bigger the root gets. When purchasing, make sure you get Zingiber officinale and not an ornamental ginger variety. You might be able to get one from the store to grow, but best would be to order root from Exotica or Gurney. To propagate, save a rhizome out from the harvest. Like a potato, it has “eyes.” Wait 2 months; then divide the root and plant the eyes 3 inches deep and 14 inches apart. Multiple plants can grow from the knobby root, one from each place where it bulges and gets closer to ground level.

**Fresh Ginger Root.** If in good condition, the root will be firm, with a light-brown outside skin that is papery. Wash, dry, and bag. It will keep in your fridge for 2 weeks. If you substitute grated or minced fresh ginger (or sliced ginger, or ginger put through a garlic press) in a recipe that calls for ground ginger (as in gingerbread), be prepared for the fact that fresh ginger is stronger and also has quite a different taste.

**Preserving.** Fresh ginger can be candied, crystallized, or preserved in syrup. If peeled and immersed in sherry, it will keep a long time, and you can use the sherry for flavoring too. For one of these sweet methods of preservation, ginger should be harvested at 8 rather than 10 months. To freeze ginger root, just wash a whole piece, dry, wrap in freezer paper, and freeze. Don’t blanch it. To cook with your frozen ginger root, just take it out, grate or slice off as much as you need, and put the leftover part back in the freezer.

**Using.** To make fresh ground ginger, trim off the leaves, cut the root into pieces, wash in very hot water, spread the pieces outside, and dry in the sun. When totally dry, grind. Ginger root has been discovered by researchers to counter motion sickness, so give your children gingerbread or pumpkin pie to take on a long drive! Or serve ginger-flavored preserves, fruit pickles, Chinese dishes (anything with soy sauce in it!), Indian food, or applesauce. Ginger is also a time-honored home remedy for worms and nausea.

**GINGER SUGAR** Into a bowl, sift together 2 c. sugar and 1/4 c. ground ginger; combine well. Transfer the mixture to an airtight container, and let stand for at least 3 days. Use to flavor cakes, puddings, squash, and applesauce and to glaze hams.

**GINGER ALE** Ginger ale is a good base for lots of other drinks when mixed with various fruit juices. If you like it stronger, just add more ginger. If your weather is cold, add more yeast. If it’s hot outside, be prepared to refrigerate it as soon as you have the desired amount of fizz. It takes only a couple of days for it to work enough to be a real “pop” beverage.

Dissolve 2 1/2–3 c. honey or 5 1/4 c. sugar in 2 gal. water. Add the beaten whites of 3 eggs and 1 T. ginger moistened with water. Put into a large pan and bring to the boiling point. Skim and set aside to cool. You’ll think you’re losing all the ginger, but don’t worry. Even though a lot of it gets caught in this skimming, the flavor is there.) When lukewarm, add the juice of 4 lemons and 1/4 t. dry yeast. Stir well. Let stand a few moments. Strain through a cloth. In 48 hours it will be ready to drink.

NOTE: Don’t seal ginger ale into anything unless you then heat it enough to kill the yeast, or you’ll have an explosion from the gas pressure, and somebody could lose an eye or something awful!

**ANOTHER GINGER ALE RECIPE** Pour 3 T. ginger root. Pour 4 qt. boiling water over it. Add the juice of 1 lime, 3 c. sugar or the equivalent in another sweetening, and 3 T. cream of tartar. Cover with a cloth so flies don’t drop in. Cool to lukewarm. Add 1 T. yeast. Let rest 6 hours; then chill and serve.

**UNFERMENTED GINGER ALE** Cut 4 oz. ginger root into small pieces and mix with 4 lemons. Cut into strips as thin as you can manage. Pour 2 qt. boiling water over the mixture and let set 5 minutes. Strain out the solids and chill your liquid. Add 2 c. lemon juice and sweeten to taste. Dilute
with cold water if it tastes strong or if intended for small children. Serve with ice and mint leaves in the glass for a hot weather special.

**MINT GINGERADE** Pour 2 c. sweetened boiling water (with a dash of salt in it—helps draw out the mint flavor) over 2 c. finely chopped mint leaves. Let stand until cool. Strain out the leaves. Add 2 qt. ginger ale or gingerade and serve very cold, garnished with a pretty mint sprig.

Now here are some recipes for nice beverage mixes you can make once your ginger ale is done. (Or start with store-bought ginger ale or fizzy water.)

**GINGER SPICED APPLE** Combine 1 qt. apple juice, 6 cinnamon sticks, 16 whole cloves, and ½ t. nutmeg, and bring to a slow boil for 10 minutes. Strain. Chill. Add 1 qt. chilled ginger ale.

**GINGER GRAPE** Combine 4 c. ginger ale, 2 c. grape juice (or grapefruit or orange juice), 3 T. lemon juice, and a sprig of mint (optional). Add the ginger ale just before serving over ice.

**GINGER, GRAPE, GRAPEFRUIT** Combine 3 c. ginger ale, 2 c. grapefruit juice, and 2 c. grape juice.

**GINGER MINT LEMON** Gather a bunch of mint, discarding the stems. Bruise the leaves and cover with ½ c. water and 1 c. lemon juice. Let soak an hour. Add 6 c. ginger ale, sweeten to taste, and serve over ice.

**GINGER PUNCH** Cook ¼ c. sugar (or ½ c. honey) in 4 c. water for 3 minutes. Add ½ c. lemon juice, 1 c. orange juice, grated rind of ½ orange, and 1 T. grated lemon rind. Cool. Add 1 qt. ginger ale (or 1 qt. tea).

**GINKGO BILoba**: You’ll find much about the amazing ginkgo biloba tree at [www.xs4all.nl/~kwanten/](http://www.xs4all.nl/~kwanten/).

**GINSENG (PANAX QUINQUEFOLIUS)**: This herb can be grown outdoors in many parts of the United States. More than 90 percent of the crop is exported. This is a great commercial crop if you can grow it, the most expensive herb in the marketplace, prized by Asians for its effects on both women and men.

A great info resource for ginseng growers is back issues of the bimonthly newsletter **Northwest Ginseng News**, which was published from 1992 through 1999. All back issues are available, with subject index, in a 3-ring binder. This is the complete reference guide to the markets, history, establishment, maintenance, disease management, weed control, harvesting, and drying of ginseng. The cost is $115, plus $5 shipping: 360-887-3128; fax 360-887-0320; [Pacific Rim Ginseng](http://www.pacificrimginseng.com), 1600 NE 236th St., Ridgefield, WA 98642; [ginseng@e-z.net](mailto:ginseng@e-z.net).

Ginseng roots are expensive, however, and they need a northern habitat to grow. In its fourth season, each plant will produce 20 seeds—unless you’ve already lost them to rodents of all sorts, who devour both root and tops. Even having seeds isn’t an easy answer. Ginseng seed, even if viable when grown or purchased, takes as long as 18 months to germinate. If it dries out before that, it is likely to die. Don’t plant ginseng in an ordinary greenhouse; it will probably die or do poorly. What it needs is well-drained, highly organic forest soil in a shady area. Plant your roots or seeds spaced 12-18 inches apart, weed conscientiously, and mulch with fallen leaves.

**Harvesting**. If you can avoid climate and rodent problems, you can indeed do well financially from a few acres of ginseng—if you can afford to wait long enough: The roots are not harvested until mid-October of the sixth or seventh year after planting! Dig the roots out with their forks intact; don’t scrape or scrub! To cure, dry them at 60°-80°F for 3 days and then at 90°F. Roots over 2 inches in diameter will need 6 weeks at 90°F to cure, smaller ones less. Have them well-ventilated and spread thinly; turn frequently to prevent mildew.

**Using**. Ginseng is a stimulant. Much of the commercial stuff is only mildly effective, but fresh ginseng can be very powerful, so use discretion.

**NOTE**: Prolonged use of ginseng can result in nervousness, insomnia, and high blood pressure.

**Goldenseal**: You can get 200+ varieties of herbs, including goldenseal, from Herbal Comfort; 573-857-2727; Hwy. 160, 7 miles E. of Doniphan, MO; HC1 Box 717, Fairdealing, MO 63939 (they also sponsor a May herb festival). Steven Foster, of Frontier Natural Products Co-op, sells goldenseal root (bulbs) and buys its product: [www.frontiercoop.com](http://www.frontiercoop.com). Meeks Farm & Nursery, 37305 160th Ave. SE, Auburn, WA 98002; 253-735-0245; [bmeeks92@ix.netcom.com](mailto:bmeeks92@ix.netcom.com); provides goldenseal roots and growing instructions to interested persons. Steve Edwards sells starts of ginseng, goldenseal, and other medicinal plants at Aspen Hill Farms: 231-582-6790; Box 750 Anderson Rd., Boyne City, MI 49712. Or buy whole plants, large or small, and a goldenseal growing video (30 minutes, $30) from NC Ginseng & Goldenseal Co.: 828-649-3536; 300 Indigo Bunting Lane, Marshall, NC 28753; [robert@ncgoldsenseal.com](mailto:robert@ncgoldsenseal.com) or [www.ncgoldsenseal.com](http://www.ncgoldsenseal.com).

Goldenseal is listed by the Convention on International Trade of Endangered Species, so be cautious when exporting. A general permit can be obtained from the USDA, Animal and Plant Health Inspection Service, Division of Plant Protection and Quarantine, 4700 River Rd., Riverdale, MD 20737-1236.

**Hemp**: For more info, read *Comeback of the World's Most Promising Plant* (Chelsea Green); and *Hemp Culture*, by Chas. Richards Dodge (1895), available from Caber Press (call/fax 503-735-3942; [tcl@teleport.com](mailto:tcl@teleport.com); [www.teleport.com/~tcl](http://www.teleport.com/~tcl)).

**Henna (Lawsonia inermis)**: You can grow the henna bush, a well-known source of cosmetic and hair products,
even in the temperate zone—if you dig it up, pot it, and bring it inside for the winter. It’s an Old World tropical shrub or small tree of the loosestrife family. It bears aromatic white flowers and small leaves. The famous dye is made from those leaves and is used to make paint for skin designs in India or as a rinse that gives hair a reddish tint. In quantity, you can give yourself a serious dye job. Available from Hudson.

**Hops (Humulus lupulus):** Once every farm had a few of these hardy perennial vines. The light green flowers of the female plant, which look and smell like pine cones, bloom in the summer and are harvested in the fall. Speaking precisely, those flowers are your “hops.” They are used commercially to flavor ales and beer and can also be used to season food. Because of its alkaline qualities, hops were also used by some pioneer bread bakers to help leaven the sour-dough. Publications on hops are available from ATTRA (800-346-9140) and WSU (pubs.wsu.edu).

**Planting.** Hops are usually started from root division of female plants, although you could start with seed. Plant in full sun. They need well-drained, fertile found, and regular and generous watering. They must be helped to grow where you want them. Their natural inclination is to grow straight up and very high. They can be trained over an arbor, up a trellis or support post, or out of a pot. And they grow fast—15–25 feet in a summer. Chop them back annually to keep them from taking over the place. They shed their leaves for winter, like grapes, but come back in the spring.

**Harvesting.** Gather the hops before they get to the shattering point and before they get frosted. Dry in an airy but shady place.

**Z Hedahooblo** This spring specialty of the American pioneers is still an epicurean treat in Europe. Cut off the top 6 inches of the earliest spring shoots of hops, and cook just like asparagus. Because of their thinness, you’ll need a lot for a meal. Adding lemon juice to the cooking water helps them hold color. Serve with a white sauce. Eating the shoots helps thin the crop, for once established, the hop vines will send up twice as many shoots as they should.

**Horehound (Marrubium vulgare):** This is also called white horehound because the leaves and stems are covered with thick silky hairs that make it look frosted. (There is a Spanish horehound, Marrubium supinum, which is not the one you want.) It’s a small, hardy perennial bush that gets around 15 inches tall. It’s a medicinal herb that has been used for centuries to treat coughing and bronchial congestion. Because of its extreme bitterness, it has usually been administered in association with sugar, as in the famous horehound candy (cough drop) of Victorian times. Either in tea or cough drops, it’s still considered a good treatment for a cough or asthma.

**Planting.** To propagate, plant a clump division in the spring, or plant seeds 1 inch deep early in the spring in a sunny, well-drained place with light soil. Thin later to 8 inches. Although horehound is hardy, it tends to die if a harsh winter is also a soggy one. Place it in a well-drained site, and mulch the roots. Available from DeGiorgi.

**Harvesting.** Just before flowers open in late summer, cut off smaller stems near the ground, and cut off just the tops of larger stems. Break into 3–4-inch sections. Dry in a warm, shaded, airy place or in an oven or dehydrator at 115°F until brittle. Store in covered glass.

**Horehound Tea** Bring 3 pieces horehound just to a boil in 4 c. water; then steep 15 minutes. Serve hot and sweetened. If unbearably bitter, dilute some more.

**Horehound Candy** These are basic instructions for making saltwater toffy.

1. Prepare the herb: Combine 2 heaping t. dried horehound and 1 c. water in a non-aluminum pan. Gradually bring to a boil. Take off heat and let steep 30 minutes. Strain. Put the horehound in a cloth, and press or twist to get every last drop of flavor. Boil juice down to concentrate. (If you want, you can also boil to make tea. The medicinal component in horehound is not hurt by boiling.)

2. Make the candy: Mix 1 c. sugar and 2 T. cornstarch in a 1 1/2 qt. non-aluminum pan. Now make the candy: Stir in 1/4 c. light corn syrup, 1/2 c. water, 2 T. margarine, and 1/2 t. salt. Cook over medium heat, stirring constantly, until sugar completely dissolves. Continue cooking, without stirring, until temperature reaches 260°F; or until a hard but shapeable ball is formed in cold water. Remove from stove.

3. Combine and finish: Stir in horehound flavoring concentrate. At this point you could substitute 1 t. of any herbal or commercial flavoring extract, plus coloring, instead of horehound. Pour onto lightly greased cookie sheet. Let stand until cool enough to handle. Grease hands and pull until it has a satin-like finish and a light color. Cut into 1-inch pieces. To store, wrap in waxed paper.

**Hors eradish (Armoracia rusticana):** Because this is strong stuff, a comparatively few plants will suffice for your family use. It is a perennial relative of mustard, not of the proper radishes. Tender, young, early-spring horseradish leaves will add a mustard-like taste to a ham or cheese sandwich with their hot taste, but most commonly it is grown for the roots. It’s a good plant for a cold climate.

**Controlling.** You can grow horseradish in a container. In fact, that might be the best way, since it can be hard to control once started in your garden; any bit of separated root will grow into a new plant. Or plant outside with edging, such as a bottomless bucket or a trench lined with plastic or slate. Give manure occasionally and water once in a while.

**Planting.** Horseradish is propagated from a root cutting. Any root has several side roots growing from the upper part of the main one. Cut those off straight-sided where they join the big root. Trim off the tip of the root at a slant. The time to do this is in the fall, when you are harvesting your horseradish crop. Store your root cuttings in damp sand in your root cellar until late winter or very early spring, when you can get into the garden. Dig 6-inch-deep trenches in fertile, heavy, well-tilled soil. You can make horseradish rows just a foot apart and space the plants also a foot apart. (These instructions are for commercial scale.) Lay the root cutting in at something approaching a 45° angle, straight-cut (thicker) end to the topside. Cover with dirt so that the top of the root is about 3 inches underground. Pack soil firmly around the roots.

**Making “Straight” Roots.** Commercial growers clean off the lateral roots by digging away the dirt from the top 4 inches of the horseradish root when it’s 9–12 inches long and stripping off the lateral roots from that area. Then they replace that dirt.
Harvesting. Some people insist that horseradish roots are tastiest when little and that harvesting should commence as soon as the roots are well started. Some are positive that horseradish is at its best only in the fall after experiencing several frosts. You can dig up the thick, white roots the fall after you planted them, any time from September until the ground freezes. You can also dig up the roots in the early spring before the leaves start. But keep in mind that horseradish makes its greatest growth in late summer and early fall, so you'd get the biggest harvest in the fall. (You could dig all winter if the ground isn't frozen and you want to.) Harvesting horseradish also keeps the plants from spreading beyond where you want them. (Any root, or piece of root, left in the ground will grow again.) About 4 days before harvesting, remove the tops of those you plan to harvest as near to the ground as possible; that makes them die back. Dig up; after digging, use them very soon, or store them.

Storing. Folks usually just dig as they need roots, because they keep best right in the ground. If you must dig and then wait, store them layered in damp sawdust or sand in a root cellar or outdoor pit. If roots are stored at 32-40°F and 90-95 percent humidity, they'll keep 4-6 months.

Preparing. It's a good idea to wear gloves when you are preparing horseradish. Keep juice away from your eyes! The hot flavor comes from the "mustard oil" they contain. Scrub roots clean. Don't be disturbed about how they look; home-grown horseradish roots are more crooked than those raised for market, which are uprooted, trimmed, and then replanted. Peel off the brown outer skin with a vegetable peeler. Drop them into cold water right after peeling to prevent discoloration. Then put in a blender, through a food grinder, or grate. (Makes you cry worse than onions.) Put the ground horseradish in a half-pint, pint, or baby-food jar.

Preserving. Add vinegar to moisten your grated horseradish and prevent it from turning color: white wine vinegar (unless you want pink horseradish) or distilled vinegar. (Cider vinegar causes the grated horseradish to turn dark within a comparatively short time.) Add ¼ c. vinegar per 1 c. grated horseradish. Optionally, add ⅛ t. salt (or sugar), or a little beet ground in to make it red. Mix, pack in jars, and tightly cap. It is important to get the grated root finished and bottled as quickly as possible. Refrigerate the prepared horseradish to keep it "hot." It's preferable to just make it as you need it, since over long usage, the vinegar will gradually evaporate and need replacement. After a month or so, your horseradish may be turning brownish and have less flavor even though kept in the fridge.

NO-TEARS HORSERADISH From Lois Rumrill, Forks of Salmon, CA: Scrub and cut roots into pieces. Pour 1-2 c. vinegar into blender pitcher. Put in several pieces of horseradish and turn blender on. Keep adding pieces of the roots until the vinegar just covers them. Pour all into clean, small jars, cap, and refrigerate. For additional batches, just repeat the process.

Lois wrote me, "I like the horseradish in the vinegar a lot better than in water, and making it this way I don't shed any tears when 'grinding' it. But if you prefer water, use water in place of the vinegar in this process. The thing you can't do with horseradish is heat or can it, because that weakens it."

Drying. Dry the root, grind to a powder, and put up in bottles in dry form. Prepared this way, it will keep much longer, but it does not make as good a relish as when grated fresh.

Serving. Serve horseradish with hot roast beef or any cold meats; or hot; or in salad dressing, with fish, or just on homemade dark buttered bread.

SIMPLEST HORSERADISH SPREAD Mix grated root with a little bit of vinegar and a big bit of thick cream.

SOUR CREAM HORSERADISH Chill ½ c. sour cream thoroughly, and then whip it until stiff. Add ⅛ t. sugar (or pinch salt) and whip some more. Fold in 2 T. of your prepared horseradish. Serve with meatloaf or ham.

FANCY SOUR CREAM HORSERADISH To the above recipe, add 1 T. chopped chives, or parsley and 1 T. vinegar, or a pinch cayenne pepper, or ⅛ t. prepared mustard, or a dash Tabasco, or ¼ t. pepper, or a combination thereof.

HORSERADISH SANDWICH FILLING Mix equal quantities of finely grated horseradish and mayonnaise. The horseradish can be topped with thinly sliced tomato, cucumber, radish, or chopped watercress. Spread between thin slices of buttered brown bread.

HORSERADISH SAUCE Melt 1 T. butter. Blend in 1 T. flour. Add 1 c. soup stock or water. Cover and heat to boiling. Stir in ¼ c. freshly grated horseradish, 1 T. lemon juice, and salt and pepper to taste. Simmer 2 minutes and serve. This is especially good with tongue.

HORSERADISH MILK SAUCE In the top of your double boiler, combine 3 T. butter and 3 T. flour. Make a paste. Gradually add 1½ c. milk and then ½ c. grated horseradish. Cook over simmering water 20 minutes. Add ½ t. salt and a pinch pepper, and you have your sauce.

HYSSOP (Hyssopus officinalis): This unusually attractive, hardy perennial herb grows 1½-2 feet high and provides an old-time medicine for sinus/chest problems. Great for bees, since it blooms profusely all summer (July-Nov.) with lovely, intense blue flowers. (There are also white and pink varieties. Grows like a low shrub (cut it back to keep it blooming), and leaves stay on most of the year, so it makes good edging for your herb garden. Birds like the seeds.

Planting. Plant seeds (viable 3-4 years) indoors and cover. Germinates easily in 10 days, if warm. (In garden, hyssop tends to self sow.) You can also propagate by division or tip cuttings of young shoots. Set out 10 inches apart in slightly alkaline soil, full sun or partly shaded spot. Can handle some drought. Available from William Dam and DeGiorgi.

Harvesting. Cutting back the plant regularly makes it keep producing the tender young leaves you'll want for harvesting. Dry as you would basil.

Using. You don't need many leaves. Hyssop is bitter, strong stuff. Use it to flavor sausages or any stuffed meat or pork, or use it in any strongly flavored meat dish, soup, stew, or vegetable juice. The tea, especially sweetened with honey, is a traditional treatment for colds, coughs, asthma, and sinus problems. Gourmet restaurants put anise hyssop leaves in salads.

IRIS: There are a multitude of varieties of iris, but old-time orrisroot powder is made from the "white flag" kind (Iris florentina). It's a perennial that grows 2 feet
high, blooms early in summer, and is cultivated for the
dried root, which is fragrant (violet-scented) and
is powdered to make a fixative for potpourris and sachets.
**NOTE: All parts of the iris plant and the orrisroot powder made
from it are poisonous!**

---

**Planting.** Rhizomes (underground stems that look like roots) are planted lying horizontally with the upper side showing just over the ground level. They prefer light soil and partial sun. The plants propagate rapidly at the root and need to be dug up in late summer (August) and divided every few years. To divide, cut them apart, leaving each piece some roots, a stem, and a fan of leaves above that. After they bloom, cut off the flower stems. That will improve the quality of the root.

**Preparing.** Use your surplus roots to make orrisroot powder. Wash the dirt off the roots with running water. Dry them like other roots. When absolutely dry and brittle, cut them into very fine chips. Dry those chips about 3 more days, stored in a paper bag in a dark, dry place. You'd better label them "Poisonous!" The orrisroot chips (or a powder made from them chipped or powdered orris to 4 c. fragrant materials (see “Potpourri}).

**JOJOBA: This plant does well in a dryish situation. The oil extracted from the seeds is used in shampoos, etc. Available from DeGiorgi.

**JUNIPER (JUNIPERUS COMMUNIS):** This shrubby perennial conifer grows to only 6 feet at most—even less in the windswept areas to which it’s naturally adapted. It’s hardy and will grow just about anywhere it can get sun. The plants are male or female. The females bear berries, which ripen extraordinarily slowly—2 to 3 years. As they ripen, they change color, from green to black with a bluish cast. Wait until fully ripe to pick. Dry and then store. Before use, crush lightly. Juniper is used commercially to flavor gin.

You can use it to flavor sauerkraut, stews, wild meat sauces, or casseroles. But go easy on it—it’s strong stuff.

**KENAF:** This is an annual non-wood fiber plant from central Africa. Related to okra and cotton, it can grow to 12–18 ft. in a 6-month growing season. It’s the great new hope for a pulp plant to replace trees in papermaking: “Kenaf Production” is at [www.attra.org/attra-pub/kenaf.html](http://www.attra.org/attra-pub/kenaf.html). The American Kenaf Society promotes products and uses of this plant: 520-741-0840; 250 E. Valencia Rd., Tucson, AZ 85706; [www.kenafsoociety.org](http://www.kenafsoociety.org). For seed and growing info contact The International Kenaf Ass’n at 903-367-7216; 101 Depot, PO Box 7, Ladonia, TX 75449; [bledso@koyote.com](mailto:bledso@koyote.com); [www.kenafseed.com](http://www.kenafseed.com).

**LAVENDER:** This semi-hardy perennial blooms from June to August with fragrant blue and purple bee-attracting flowers—possibly the most wonderfully scented plant, fresh or dried. It grows 1–3 feet high (trim back after harvest of flowers if you want it shorter). Catherine Shirley wrote me, “The true lavender is a small shrubby plant native to southern Europe. The plant thrives best in hot sun and light and rather dry soil well supplied with lime. On low and wet land it is certain to winterkill. It also should be loosely covered to prevent the snow from getting inside the branches which freeze and thus winterkill.”

There are many different varieties: English lavender (Lavandula vera), spike lavender (Lavandula spica), and French lavender (Lavandula stoechas). Lavandula angustifolia is another name for all three. English lavender is the hardiest, and mulching can get it through a winter. Dwarf kinds grow 12 inches tall and are suited to a pot life, 1 or 2 plants in a 6–8-inch pot. More tender varieties are best brought in for the winter.

**Planting.** Be choosy about the plants you buy. Some lavers are not of commercial quality and do not produce quality oil. Lavender seeds can live 2–3 years. The plant can be started from seed, but it grows very slowly. It is more readily propagated from stem cuttings (6 inches long), by layering, or by division. Plant deep. Cuttings should be set in well-prepared soil in early spring, 12–15 inches apart, in rows spaced to suit the cultivation intended.

Lavender can be grown as a hedge to give plenty of flowers for harvesting. Frequent and thorough cultivation is desirable. Growth is slow, and plants do not produce any considerable quantity of flowers for several years, but full crops may be expected for some time thereafter if the plants are given proper care. They should not be watered very much. Lavender grown in poor soil that is limy and gravelly produces the most strongly scented flowers. Available from William Dam and DeGiorgi (3 varieties).

The Sequim area of Washington state has many lavender specialists who offer plants, products (aromatherapy, sachets, dried lavender, lotions, fragrance, etc.), and/or volume plugs. Here are some specifics:

**Cedarbrook Herb Farm: 50+ varieties; 360-663-7733; cedbrook@olypen.com; www.lavenderfarms.com/cedarbrook; 1345 S. Sequim Ave., Sequim, WA 98382.

**Lavender & Herb Growers of Franklin County, MA:** 413-772-0858; fax 413-772-8858; 56 Glenbrook Rd., Greenfield, MA 01301; [www.laverland.com](http://www.laverland.com).

**Olympic Lavender Farm:** 360-683-4475; 1432 Marine Dr., Sequim, WA 98382; [www.lavenderfarms.com/olympic/main.htm](http://www.lavenderfarms.com/olympic/main.htm).
Purple Haze Lavender Farm: Mike Reichner; 888-852-6560 (orders); office 360-582-3088; fax 360-681-5427; 180 Bell Bottom Rd., Sequim, WA 98382; purphaze@olypen.com; www.purplehazelavender.com. Great website and links!

Rancho Allegre has 5,000 lavender plants and produces essential oil, dried flowers, 20 lavender varieties, and plugs: 650-879-1876; PO Box 538, Pescadero, CA 94064; ditz@earthlink.net.

Harvesting. Gather the flowering tops or “spikes” as soon as the first buds on a spike begin to open. That’s when the flowers have their strongest scent. Catherine wrote, “A lot of fragrance can be lost if they’re left standing too long, especially if rain falls on them. If the plant got wet already, cut without waiting for all buds to bloom. For production of oil, the leaves are generally used rather than the flowers, and they are distilled at once without drying. (To prevent plants turning woody, prune them back sharply every year after harvest.) If dry flowers are wanted for sachets, shake the spikes over spread-out paper, as some buds will fall off. Carefully hang the spikes up to dry in an airy room (in the shade). Takes about 3 weeks. Once dried the flowers are stripped from the stems by hand.”

CAUTION: Inhaled lavender can cause sneezing, tearing, and even vomiting, so wear a dust mask or respirator while working.

Using. Old-timers kept it simple; they just hung some bunches of dried lavender from the ceiling or placed them between folded clothes in a drawer. But the dried flowers and buds can be used in bath water, potpourris, fragrances, and sachets for scenting linens; as a tea herb; as a scent for potpourri; as a tea herb; as a scent for sachets.

Lavender Bookmarks. Catherine wrote, “Real short lavender spikes with flowers and buds can be artistically arranged between 2 small squares of nylon tulle, nylon organandy, or any stiff transparent material in a sandwichlike fashion. Secure the spikes with glue that dries clear or a few small staples so the spikes do not move around. Then sew patches of pretty braid or tapes around the edge on all sides to suit your fancy. Good gift for people who read a lot.”

Lavender Sachet Powder. Mix ½ oz. dried powdered lavender flowers with ½ t. powdered cloves. Sew them up tightly in a little cloth pillow and leave the pillow in a bureau drawer to perfume the clothes. That’s old-time elegance.

Lavender Water. Dissolve 3 drops oil of lavender in 2 c. distilled water. Age at least a week. It’s better with a lump of sugar in it, but then it has a tendency to ferment and go bad. A perfume.

Lemon Balm: See “Balm, Lemon.”

Lemongrass (Cymbopogon citratus): This tender Asian native looks like a green onion, but the leaves are greyish green and spearlike. It’s not pretty. It can be grown in the temperate zone but must come indoors in a container for the winter because frost kills it.

Planting. One way to get started is to find it at an Oriental grocery. Look for some with the root still on it. Put it in water in a glass jar. Set the jar by a window that gets lots of sun. The roots will grow. Once the roots have expanded a good bit, plant it where it can get 4–6 hours of sunshine each day. Water only once in a while, but water thoroughly when you do.

Using. Lemongrass needs to be harvested. Cut the long blades, wash, and drain. To use fresh, cut into short sections. Or dry those sections at 110°F until crisp and crumbly (6–8 hours). You can powder and store it, but it will lose its flavor quickly. Its peculiar citrus flavor is great in Mexican and Asian cuisine. Some people like a tea made from its steeped dry leaves. Soak dried lemongrass in hot water for an hour to get the flavor out.

Lemon Verbena (Lippia citriodora, Formerly Aloysia citriodora): This is an attractive perennial shrub (up to 6 feet tall) with pink flowers.

Planting. Plant after last frost, and bring back in before the last warm summer evenings are over. To propagate, make cuttings of shoots early in the summer and plant in light, well-drained soil.

Harvesting. The lemon verbena leaves are at their best during early apple harvest season. You can dry leaves for winter use or use fresh (finely chopped) to make a soothing tea, good at bedtime. For lemon flavoring, add fresh lemon verbena leaves to drinks, fruit desserts, fruit salad, and jellies. The leaves are also good in potpourri or sachets.

Licorice: Glycyrrhiza glabra is the plant from whose root licorice flavoring comes. It’s a perennial. Plant seed in spring, or do root division in spring or fall. To harvest, wait until the roots are 3 years old. Licorice has a mild laxative effect, a very sweet taste, and a tradition of flavoring cough syrups and candies.

Lovage (Levisticum officinale): This Mediterranean-originating hardy perennial resembles angelica, grows 6–7 feet high, and is considered by some to be one of the loveliest herbs.

Planting. Plant seeds (they won’t keep) in fall or spring, or do root division. Plant in moist, fertile soil, in sun or light shade, 12 inches apart. You need only a few plants. Dies in winter, but comes back from roots in spring. Available from William Dam and DeGiorgi.

Using. You can harvest and use in your kitchen lovage leaves, seeds, stalks, and roots, fresh or dried. They all taste somewhat like celery and can be used to flavor salad, soups,
or meats. (Go easy; they're strong.) You can save the seeds and use them anywhere you would celery seed. To harvest roots, give them 3 years to get well-grown.

**MACE:** This spice comes from the seed (nutmeg) of the tropical nutmeg tree (see “Nutmeg”). It has an outer shell that is covered by a lacy red network called aril. The peach-like fruit of the tree is edible. Save the kernel. Remove the aril and sun-dry. The dried pieces of aril are called blade mace. When ground, the powder is called mace and is used to flavor meats, fruit, sweet baked goods, and jams—but nutmeg is considered the better choice for sweet dishes, with mace the better choice for meat.

**MARIGOLD, POT (Calendula officinalis):** This hardy annual flower has a bold and pleasant golden color. Of all the varieties of marigolds, the pot marigold (also known as calendula) is the most important. The flowers and leaves of all marigolds can be used in salads or soups, but the pot marigold also yields an ointment used by traditional healers to treat ulcers and wounds. Plant in fall or early spring in full sun. Because pot marigold repels many garden insect pests, organic gardeners like to grow lots of it around or in the garden. Petals are good in salads; you can also add petals (or a strong petal tea) to casseroles, soups, cakes, and puddings.

**MARJORAM:** This is one of the main branches of the Orig-anum family (the other is oregano). Some marjorams are merely ornamental. The culinary varieties are pot marjoram (Origanum onites) and sweet marjoram (Origanum majorana). Sweet marjoram, the generally preferred type, comes from the Mediterranean area and is “semi-hardy,” unable to withstand frost and snow, so in zones 1–7 it must be grown as an annual or taken indoors. It grows 1–2 feet high, and has small gray-green leaves and small lavender or white summer blooms. If your climate allows it to grow as a perennial, it will enlarge each year to a 2–3-foot-wide bush shape. That one plant will probably be enough to meet your kitchen needs for marjoram.

**Planting.** Start marjoram from seeds (viable for 2–3 years), cuttings, division, or layering. Seeds germinate easily but slowly (2 weeks). It helps to soak seeds in water overnight before planting and keep planted areas moist until they're up. Plant after frost or, for most northern gardens, start in early spring in full sun. Before pot marigold repels many garden insect pests, organic gardeners like to grow lots of it around or in the garden. Petals are good in salads; you can also add petals (or a strong petal tea) to casseroles, soups, cakes, and puddings.

**Harvesting.** For fresh leaves, cut marjoram year-round, anytime after the plant is at least 5 inches tall. When the plant begins to bloom, take the top 4 inches and dry. You can harvest again in the fall by cutting the whole plant off and drying. Don't wash; just sort the leaves and dry like basil. Marjoram is unusual in that its flavor is improved by drying!

**Using.** Marjoram is a basic herb in Italian cooking (spaghetti sauce! poultry stuffing!) and sausages. It makes one of the best herb butters. In the kitchen, use on hot vegetables, especially zucchini, potatoes, lime or green beans, and peas. Use fresh or dried in egg dishes, stews, soups, and gravies and with fish or meats. Orange juice flavored with marjoram makes a nice herb jelly. And you can make a good herb vinegar with it. Also good in sachets.

**MARTYNIA:** This unusual annual from the botanical family Martyniaceae is a native of the southwestern United States and is also called Proboscidea. There are more than a half-dozen types that come from various regions, from the United States south to Baja Mexico and plains native, the plant has bristly leaves.

**Varieties.** Proboscidea fragrans, a common Mexican type, has bright red flowers whose pods pickle especially well. *P. lutea* has yellow blooms and is from Brazil. *P. annua. P. par-viflora,* and *P. louisianica* (a.k.a. *P. jussieus*) all also have edible pods. *P. louisianica* is considered the best risk for northern gardeners.

**Planting.** You need 120 warm days to get martynia from seed to a harvest of pods. This is easy if you’re gardening in the south. Northern gardeners should start martynia in a protected place. In the garden, plant 1 inch deep, rows 3 feet apart. In either case, plant near the end of February or early in March. Indoor plants in individual pot should go to the garden about the same time as your nightshade fruits (tomato, pepper, eggplant). Plant them in the garden 4 feet apart, rows 3 feet or further apart in full sun and fertile soil. They need to be that far apart because they spread out widely, although they get only a few feet tall. Seed available from DeGiorgi, Hudson, and Park.

**Harvesting.** Martynia will start flowering about 6 weeks after germination. Its large (2 inches across), lovely flowers grow in clusters of up to a dozen at the end of each stem. Each is followed by an edible seedpod that somewhat resembles an okra pod (fuzzy and green) but has a curved shape. Harvest while still tender and green. They are good cooked (either whole or sliced) in soups and stews, pickled using a dill recipe, or cooked, chilled, and served with a vinegar/oil dressing. Flower arrangements like to let them dry on the plant because of their unusual double-forked tip, which they use in dried flower arrangements, etc.

**MEXICAN PARSLEY:** See “Coriander.”

**MEXICAN TEA:** See “Epaezote.”

**MIGNONETTE (Reseda odorata):** Its name means “little darling.” This plant is not for culinary use, but it dries well and is useful for potpourri because of its intense musky scent. Available from Thompson & Morgan, William Dam, etc., it’s easily grown from seed and is not particular about soil. Mignonette is best suited to a dryish place with a warm summer.

**MINT (Mentha):** The most important thing to understand about mint is that it is a large family of plants with various characteristics and uses. There are purely ornamental mints that are not good in the kitchen. There is an insecticidal mint, pennyroyal, that can be deadly poisonous and should never be consumed in any form. (See “Pennyroyal.”) Mints are just about the easiest herb to grow—very hardy perennials that can be overly aggressive in the garden. Other than lemon balm and horehound (which have their own entries elsewhere in this section), the main culinary mints are listed below.

**Apple Mints.** These are a whole family in themselves. *M. rotundifolia*, called “apple mint,” “wooly mint,” or “Bowles
variety," is popular in English and Italian kitchens but is not considered the best culinary mint in the United States, where it grows wild. The American apple mint (Mentha × verticillata) is preferred in the United States.

Ginger Mint (Mentha × verticillata). Also called "Golden Apple," this has a spicy mint scent and mixed gold and green leaves. It grows on the tall side for a mint, to 2 feet.

Peppermint (Mentha piperita). This grows 3 feet high and has small purple blooms and dark leaves with toothed rims. Peppermint has been scientifically proven effective in treating digestive problems. It's also reputed to have soothing effect, so chew on a peppermint leaf! For a good tea, mix half peppermint and half rose hips. Peppermint and spearmint are sizable commercial crops. Peppermint oil is used to make candy and medicines. It isn't an important culinary mint, but it is the important medicinal mint.

Orange mint (Mentha × piperita, var. citrata) is a variety of peppermint. It's also called bergamot or eau de Cologne mint. It has light blue flowers and nice minty fragrance. It's good for scenting bath water. Available from William Dam, Thompson & Morgan, DeGiorgi, etc.

Pineapple Mint (Mentha suaveolens "Variegata"). This kind has variegated foliage, soft leaves, and a pineapple scent and flavor.

Spearmint. There are several varieties, including Mentha spicata and Mentha viridis. This is the most commonly grown mint; it has pointed deep green leaves and grows 1½-2 feet high. Spearmint is good with new potatoes and green peas and is used to make mint jelly and mint sauce. Mentha spicata is available from DeGiorgi.

Planting. Planting from seed is one option. Or to get new plants from old, just dig up and replant runners, plantlets, or root divisions. The little plantlets grow just below the soil surface. Be careful to cut between rather than through any baby or adult plants. Or plant a 6-inch piece of root 2 inches deep in fertile soil in spring. Mints can handle semishade (as little as 4-6 hours of sun per day), but they are more aromatic in drier, brighter situations. Supply lots of water to get them going. Once established, they'll thrive on its assigned growth area, or plant in a sunken, bottomless wide, shallow pot for mint grows out rather than deep down. But mints can be left out through the coldest winter, and even harvested in winter! Not everybody has boisterously growing mint, though. You can use regular dirt, but the more clay in your soil, the less likely the mint is to be able to handle waterlogging. Put enough stones or broken crockery in the bottom of the pot for good drainage.

Choose a shallow pot rather than a narrow, deep one, since mint is a surface spreader rather than a deep grower.

Harvesting. Cut off plant tips; wash, dry, and cut off the leaves with your scissors. Mint can be harvested anytime, even after blooming. The more you cut, the faster it will grow. Use fresh, frozen, or dried.

Preserving. Frozen mint keeps its strength better than dried. To freeze mint, just wash, dry, and wrap a few tips of mint at a time in freezer paper or a baggie. To dry it work quickly, or the mint leaves' color will turn black. Gather only as much as you can dry in 1 batch. Spread leaves thinly over surface and dry in shade or in oven/dehydrator at 110°F. Two tablespoons fresh chopped mint are equivalent to 1/4 t. dry mint or 1 t. mint extract.

Using. Good in Greek cooking and potpourri and sachets. Mint goes especially well with lamb or mutton, peas, baby potatoes, little carrots, and parsnips, and in salads, cucumber sandwiches, or a cup of tea. Crush fresh leaves just before using to release flavor. Chopped mint is good in a drink made with fresh tomatoes plus salt and pepper to taste.

**BASIC PEPPERMINT TEA** Pour boiling water over a handful (4 T.) of peppermint leaves. Steep 5 minutes (less if desired less strong). Strain, pour into serving cups, sweeten to taste. Serve with affection.

**MINT SYRUP** Boil 1/4 c. water and 1/4 c. sugar for 5 minutes. Add 6 T. chopped mint leaves and 1/2 c. lemon juice. Let stand overnight. Strain. If you want it greener, color with food coloring. Put into jar and store in refrigerator. Add to iced tea, lemonade, punch, and the like for mint flavor. Garnish drink with a fresh sprig.

**MINT JELLY** You'll need 1 c. fresh mint leaves, 1/4 c. boiling water, 2/4 c. sugar, and 1 qt. apple juice. Wash mint leaves; strip from stems. Add boiling water and 1/4 c. sugar. Let stand a few hours. Bring to boiling point and strain through several layers of cheesecloth. Add the remaining 1/4 c. sugar to apple juice and stir until it reacts to jelly test. Skim and pour into hot, sterilized jelly glasses. Seal with paraffin. If the color is too pale, add a little green food coloring.

**ICED MINT TEA** Peel and quarter a lemon. Combine 4 sprigs mint, juice of the lemon, 2 T. sugar, and 2 c. hot water and let steep a half hour. Strain. Add strips of the lemon peel. Chill and serve.

**MINTED GREEN PEAS OR NEW POTATOES** Add some sprigs of mint while boiling. Figure about 6 leaves per 4 c. vegetables plus 1 t. of butter.

**PINEAPPLE-MINT DRINK** In a blender, combine 1 c. mint leaves with 1 c. pineapple juice. Add more (about 3 c.) pineapple juice to dilute to taste. Serve over ice cubes.
**MINT VINEGAR SAUCE** For roast lamb or chops. Wash and then chop very fine 1 c. mint leaves. Dissolve 1 T. sugar in 1 c. vinegar. Add the mint and let stand in the liquid 1 hour. Optionally, add 1 T. lemon juice and a dash each of salt and pepper.

**MINT JELLY SAUCE** Combine 1 T. chopped mint with 1 c. currant jelly in a saucepan over low heat. Serve hot with lamb or mutton.

**BAKED PEARS WITH MINT** Place 3 large, thinly sliced pears in a rows in a greased baking dish. Sprinkle with ¼ t. salt and 2 T. sugar. Dot with butter. Cover and bake at 300°F for 30 minutes, or until tender. Garnish with mint sprigs and serve hot.

**FRUIT SALAD DRESSING** Combine 2 T. mint vinegar, 2 T. cream, and 1 c. mayo.

**RUTH'S MINTY TABOULI** Pour 4 c. boiling water over 1¼ c. cracked wheat and let stand until fluffy (about 2 hours). Drain well; then mix with 1 c. cooked garbanzos, ½ c. minced fresh parsley, ¼ c. minced fresh mint, ¼ c. minced scallion or onion, and 3 chopped tomatoes. Dressing: 1 c. lemon juice, ½ c. water, dash tamari. Chill dressed salad well before serving (at least 2 hours), and serve on lettuce leaves.

**MUGWORT (ARTEMISIA VULGARIS)**: Also called Lactiflora. Do not eat. Plant this perennial by seed outdoors. When dried, makes a good homemade moth repellent in your cedar chest and closet. Available from Redwood City.

**MUSTARD:** There are 2 basic mustard varieties (black and yellow) whose seeds are used for seasoning. They are ancient and important culinary plants, their usage dating back at least to the Greeks. In addition to that spreadable yellow product, their unground seeds can be used to add a spicy hotness to recipes. Indian mustard, spinach mustard, and “mustard greens” are close relatives. Mustard seed can be very tasty and to add spicy hotness to recipes. Available from DeGiorgi.

“White” or “Yellow” Mustard *(Brassica sinapéolis alba).* This variety gets about 1½ feet tall. Plant it away from your garden patch because it freely self-sows and can become a problem weed. It’s not the wild mustard we know in the Oregon and Idaho valleys. Yellow prepared mustard is made from it, and the whole mustard seed is used in pickling mixtures and to add spicy hotness to recipes. Available from DeGiorgi.

**Black Mustard *(Brassica sinapéolis nigra).*** This hardy annual herb can get 4 feet tall. Plant in fertile, moist ground for best seed production. Has smaller blackish-red seeds. The seeds are a good flavoring and preservative for mayo, curries, and salad dressings. In France this is the prime ingredient for mustard paste. In the US it’s used as a pickling spice. Available from DeGiorgi.

**Harvesting and Processing.** Harvest when pods have turned yellow but before they have finished ripening; once dead-ripe, they shatter and the fine seed is lost onto the ground. The harvested pods should then be spread out to dry—outdoors in the sun is fine. Once pods are thoroughly dry, smash them to free their seeds and sift to separate seeds from pods. Now work with the seeds in a mortar to loosen the hulls from the seeds. Sift and discard the papery hulls. The seeds can be used as condiments as is. Or grind your mustard seed to make wet mustard recipes. The finer you grind it, the smoother your mustard will be. But there is an important element in the processing of commercial dry mustard that I haven’t been able to find out for you, so your homegrown mustard won’t be quite the same as the commercial kind.

**Using Leaves and Buds.** Add mustard leaves that are very young and tender to soup, and cook. Or add them, in small amounts, to a salad and eat raw. Mustard buds are edible too. Gather unopened mustard buds in the early spring and serve them like broccoli with a cheese sauce.

**Mustard Plaster.** These were used in traditional medicine. I well remember my mother’s mustard plaster remedy for a chest cold. Mix 1 part mustard with 8–10 parts flour. Add lukewarm water until you have a smooth paste. Then spread between 2 pieces of cloth, such as muslin or old sheets of flannel. Rub the chest well with Vaseline before applying to prevent blistering, and don’t leave it on after the skin is well-reddened. Keep away from mouth and eyes.

**Wet Mustard Recipes.** Wet mustard is ground dry mustard moistened with vinegar or water, and sometimes with other seasonings added. For a thickening agent, cook your mustard mix together with beaten eggs, or evaporate to a spreadable state. Note: Commercial mustard powders vary in their ingredients and therefore also in their hotness and ability to absorb liquid. If any mustard is too spicy-hot, steaming it in a heatproof container for 15 minutes may make it milder. For more gourmet homemade mustard recipes, see Better Than Store-Bought by Helen Witty and Elizabeth Schneider Colchie (Harper, 1979).

**HOMEGROWN MUSTARD** In a blender combine ground mustard seeds with enough wine vinegar to moisten, a bit of allspice, some peppercorns, and a pinch salt. Here’s a more precise recipe: Combine ¼ c. mustard seeds, ¼ c. red wine, and ½ c. wine vinegar, and let soak overnight. Then put in blender. Add ¼ c. water, ¼ t. allspice powder, pinch pepper, 1 minced garlic clove, ½ t. salt, 1 broken-up bay leaf, and 1 t. honey. Blend on slow. Then move mixture to the top of a double boiler and simmer over boiling water until the mix has thickened. Store in fridge.

**BASIC WET MUSTARD** Mix 1 part dry mustard powder and 1 part wine vinegar. Add to taste: salt, mustard seed (cracked or whole), turmeric, garlic, other herbs, sugar or honey, etc. Then use your choice of thickening agent or process.

**SWEET-HOT MUSTARD** Combine 2–4 oz. dry mustard (how much depends on how hot you like it) and 1 c. vinegar. Cover the bowl and let rest in cool place overnight. In the morning, beat together 3 eggs and ½ c. sugar. Add to mustard/vinegar mix. Cook over medium heat, stirring constantly, until thickened (about 8 minutes). Refrigerate 2 days for flavor to ripen before using. Optionally, combine the mustard you just made with 2½ c. mayonnaise for a milder, delicious mix.

**SPICED MUSTARD** Make by first spicing the vinegar and then adding other ingredients. Put 2 T. finely chopped onion, 3 bay leaves, and 1 chopped clove garlic into ½ c. vinegar. Cover and heat in a moderate oven (325°F) for about 20 minutes. Strain out the solids. In another container, mix the amount of dry mustard you want to make up with a pinch each of powdered cinnamon and cloves and a bit of sugar. Gradually stir in the hot vinegar until the mustard is the consistency you want. Save the rest of the spiced vinegar for
making salad dressing or more spiced mustard when you want it. Pack your mustard mix into small jars and cover when cooled.

**Dijon Mustard** Combine 1 large chopped onion, 3 minced cloves garlic, and 2 c. dry white wine in non-aluminum pan. Cook on low heat 10 minutes. Then let steep 15 minutes. Strain and discard solids. To your flavored liquid, now add 4 oz. dry mustard, 1/4 c. honey, 1 T. plain-flavored cooking oil, and salt to taste. Simmer again, stirring constantly, while you evaporate it until it’s thick enough to spread.

**Myrrh** See “Sweet Cicely.”

**Myrtle (Myrtus communis)**: This tender perennial fragrance herb gets 3 feet high when grown outside in a warm enough climate. Its leaves and flowers are useful in potpourri and sachets.

**Nasturtium**: This annual, one of the easiest plants to grow, originated in Peru, traveled back to Europe with the conquistadores, and is now known on most continents. Its pretty, brightly colored summer flowers (cream, yellow, orange, red), leaves, seeds, and stems are all edible and have a peppery taste. There are 2 basic species, the tendril-climbing (*Tropaeolum majus*) and the dwarf (*Tropaeolum minus*), which is nice in a flower border.

**Planting**: Start these tender annuals from seed in late spring and warm soil. They need full sun and well-drained soil. For your plants to be loaded with blossoms, their soil must be poor; fertile soil results in more leaves but fewer flowers. Plant ½ inch deep, rows well spaced apart. Nasturtiums do well in pots (2-3 seeds in a 6-inch pot). The climbers are dow casing or up a fence or trellis. It tends to reseed itself. Nasturtium plant parts, however, are not dried. The seeds are the only part used to dry. The blossoms are minimal and the flowers are ephemeral. The flowers are used in salads and sandwiches or added to chutneys or pickles. Cut in fancy shapes and add to soups, stews, veggie dishes, sauces, or as a garnish. You can use nasturtiums in pizza or add to soups, stews, veggie dishes, sauces, or as a garnish.

**Harvesting**: Any and every part of the nasturtium plant is edible. Pick leaves and flowers fresh anytime you want them. Nasturtium plant parts, however, are not dried. The small green seed pods are picked green and pickled like capers. Pick just after the flower has dried off and before the seed dries. If your nasturtium seeds are appearing during an inconvenient period of time, pick them as they are ready. Nasturtium seeds are appearing during an inconvenient period of time, pick them as they are ready and keep in a brine of ½ c. salt to 4 c. water. Change it every 3 days. When you have all the seeds you are going to get or that you want, you can go ahead and pickle them.

**Using Flowers**: Add the fresh flowers to salads and sandwiches, plain and fancy. Add leaves to sandwiches and salads. To make nasturtium blossom sandwiches, wash and dry the blossoms. Lay on buttered white or brown bread; if you wish, add mayo. Fresh seeds are also good in sandwiches, and add a blossom to the top of each sandwich.

**Pickling Nasturtium Seeds**: Below are some recipes for pickled seeds. To preserve, pack in ½-pint jars and process in a boiling-water bath 15 minutes. To use, sprinkle on pizza or add to soups, stews, veggie dishes, salads, sauces, sandwiches, and poultry stuffing.

**Pickled Nasturtium Seeds (Plain)** Brine seeds in salt water for 2 days, then in cold water for 1 day; drain and pack with a hot vinegar solution.

**Spiced**: Put 1 c. white vinegar in a pan. Add ½ t. salt, 1 bay leaf, and a few peppercorns, and boil. Remove from heat and let steep 2 hours. Strain. Pour over nasturtium seeds.

**Sweet**: Combine ¼ c. cider vinegar and ¼ c. sugar and pour over seeds.

**Fancy**: In a pan bring to a boil 1 c. vinegar, 2 sliced cloves of garlic, ½ t. each dill seed and mustard seed, and 1 t. each peppercorns and salt. Strain and pour liquid over 2 c. nasturtium seeds.

**Capered**: Pickle using the recipe for capers. (Or you can pickle capers using these recipes!)

**Nettle (Urtica dioica)**: A common perennial weed, this is also called the common stinging nettle because of its leaves, which have fierce little stingers that poke through your skin at the slightest touch. Then you get red welts that burn and itch like crazy, on and on. (An old-time remedy for nettle stings is crushed mullein leaves pressed on the welts.) I used to have to navigate around a dense patch when I was a little girl hauling buckets of water up from the “crick” to fill the porch water tank. Miserable stuff. I’d just as soon never have anything to do with nettles again. But they are edible once cooked—worth considering if you’re starving for food or looking for a dish that’s also a conversation piece (“How I captured the nasty nettle”).

**Planting**: I wouldn’t plant it on purpose. It self-sows and thrives under most conditions. However, seeds are available from William Dam.

**Harvesting**: Don’t touch nettles with bare skin until cooked! The points are tiny silica needles that inject formic acid. Use gloves to pick, clean, and work with them in the kitchen! Use the tops of young plants in spring, when they are about 6 inches tall. Otherwise, take only the top rosette of just-growing leaves and the topmost bud plus the few leaves just under that. You can go on harvesting to mid-June.

**Using**: Don’t let them sit around. Pick and then boil them. The cooking disarms them. Serve sprinkled with caraway or dill seed. Nettle leaf tea, sweetened with honey, is an old-time remedy for a stuffy nose or a sore throat. Nettle root makes a yellow dye. A nettle poultice is an old-time remedy to stop the bleeding from a wound.

**Nettle Fabric**: The fully mature nettle plant (a hemp relative) can be used to make a fiber that can be woven into a fine white linen-type fiber nearly as strong as flax and comparable to cotton in its uses. Nettles were commonly used to make a linen-type fabric in Europe years ago. American Indians used the nettle variety *Urtica gracilis* for that purpose.

**Nettle Rennet**: Combine 6 c. very strong nettle tea with 4 c. uniodized salt. Use just enough to get the curdling action for your cheese-making.

**Cream of Nettle Soup**: Steam 4 c. young nettle leaves until soft. Puree. If they need more liquid, add a little meat or vegetable soup stock. Melt 2 T. butter. Cook 2 T. grated onion in the butter. Add 2 T. flour to that and cook, stirring, until mixture is turning brown. Now gradually add 2 c. more stock, salt and pepper to taste, and the nettle puree. Simmer on low heat 10 minutes. Add 2 c. milk and heat just warm enough to serve. Good with grated cheese sprinkled on top.

**Nutmeg**: Nutmeg and mace both originate from the same tall East Indies evergreen tree, *Myristica fragrans*. The edible, peach-like fruit of that tree has a shell and inside that a brown seed, which is the nutmeg. The nutmeg trees
are male or female. They take about a decade to bear but then continue for a half century more. Eat the peachy fruit. Strip away the "aril" (mace) from the outside of its seed and dry. Sun-dry the pit a few weeks. This will cause the nutmegs inside to shrink enough so you can hear them rattle in there. Take off shell, finish drying the nutmegs, and store for use.

Using. Grind as needed. It's always better when fresh. Burn as incense or use to flavor desserts, sausage, or pickles.

OREGANO: Be choosy about which oregano you buy. There are several varieties, but only one is of culinary quality. Wild marjoram (Origanum vulgare) is weak in flavor. If a plant is called Origanum spp., that means no one is sure just what it is. Hold out for Greek oregano (Origanum heracleoticum), which is the real stuff.

Planting. Buy and then, after last frost, transplant to a sunny place in your garden that's well drained. Plant about 10 inches apart. It gets 1–2 feet high. Greek oregano is a winter-hardy perennial. It's also drought resistant once mature.

Container-Grown. The flavor of leaves grown outside is much better than that of those grown inside, but oregano can also thrive potted. You could use 4–5 plants. Start in 8–10-inch pots. If you don't repot to larger pots by at least the end of the third year, the plants will stop thriving. Eventually the stems get woody; then you need to replace the plant. Propagate from cuttings or root divisions.

Using. Harvest and dry like marjoram. Dried oregano is as good as, or maybe better than, fresh. Rub it to a fine powder before storing. Keep it cut back by adding it to any Italian, Mexican, or Greek dish. Use fresh or dried in chili, tomato sauce, salad dressings, pasta, hamburgers, wild game, broccoli, and eggplant. The leaves can also be used to dye.

ORRISROOT: See "Iris."

PAPRIKA: See "Peppers" under "Nightshade Fruits" in Chapter 4.

PARSLEY: There are several varieties of this easy-to-grow, popular herb, a dark green, semi-hardy biennial that does well just about anywhere. Curly parsley (Petroselinum crispum), the one restaurants use because it keeps its freshness longest, gets 8–10 inches tall. Its cousin, the stronger-flavored flat-leaf or plain-leaved parsley (Petroselinum hortense), is a little harderier to both cold and wet weather than curly, and gets much bigger—3 feet tall. Celery-leaved (or Neapolitan) parsley grows stalks that can be eaten like celery. Forian parsley) Mitsuba is a perennial Japanese parsley. For Oriental parsley, a dark green, semi-hardy biennial that does well just about anywhere. Curly parsley is a little hardier to both cold and wet weather than flat-leaf parsley, but hardier varieties can stand some freezing weather, so consider starting it outside. Germination takes 3–8 weeks (a 1–14-day pre-soak in cold water helps). Parsley seed is viable for only 1–2 years and has a high failure rate in germination, so overplant it. Keep the soil moist during its early period. Parsley takes about 90 days to mature. Time your plantings if possible, so you have it fresh year-round. Most seed houses carry some parsley; good variety available from William Dam, etc.

Container-Grown. Parsley does well as a potted plant and can even be dug up in the fall, potted, and brought in for fresh winter parsley—if you make sure to get all the roots, don't let them get exposed to air, and set plants in a big, deep pot because of the roots. Let soil dry between waterings. Two or three parsley plants will be enough for a family.

Harvesting. You can expect a yield of 50 lb. per 50-foot row by commercial standard. Harvest all you want anytime after the plants have had a good start. Take leaves from the outside of the plant just as they mature. Let the center leaves finish maturing. If you are in a warmer climate zone where you can leave parsley out all winter, you can harvest it right on through its first year and first winter, until it starts to flower in its second year. In harsher zones (even quite northern ones), your plants may survive outside year-round, but they won't grow leaves in frigid weather. Survival depends on the parsley variety, your climate, and how well they're mulched (cover with thick hay or leaves after first few frosts). The second year you must either let it make seed (cuttings from a parsley plant going to seed are bitter and worthless for cooking), or else cut off the flowering stalk as soon as you recognize it. If you do that, you can keep on cutting it for culinary use. Once parsley goes to seed, just yank the plants out and put them on the compost heap unless you're saving the seed.

Saving Parsley Seed. Parsley is a biennial. In its second year, uncover mulched plants in the spring. Parsley flowers have both female and male parts and are pollinated by insects. They do need isolation from other varieties. Once some seeds have turned brown, which means they are mature, go out periodically and rattle the parsley flower head around inside a paper bag. The ripe seeds will fall off, while unripe ones will stay on. When most of the seed head is brown (around September) you can cut the head off and spread it on cloth or paper to finish drying. Seeds are viable only about 2 years.

Chopping Fresh Parsley. Pinch the tufts of parsley tightly between the thumb and forefinger of your left hand; then cut finely with your kitchen scissors. Try adding parsley to fresh corn in place of salt.

Drying. Cut off parsley tops with new leaves. Dry either whole or chopped. Spread thinly over your drying surface. Dry in oven or dehydrator at 110°F. Drying parsley bunches outdoors is risky; they don't dry easily. They're done when the tops of the leaves start to crumble. Store for use.

Using. Parsley is grown for its low-calorie, attractive, edible leaves, which contain lots of vitamins and minerals, including lots of vitamins A and C. Add to meat, stew, soup, salads, vegetables, carrots—anything but fruit—just before you serve it, for parsley shouldn't be cooked.
Or use a pretty sprig as an edible garnish beside food on a plate, or as a bouquet in the center of the table. Eating boiled parsley is said to be helpful for a urinary stone and for eye inflammation. It's also said to be a breath sweetener, a natural antidote to garlic and onion breath.

**PARSLEY BUTTER** Add the juice of 2 lemons, drop by drop, to 1 c. softened butter. Keep stirring as you add it— it takes quite a while. Then add 2 T. crumbled dried parsley. Good as a clam dip.

**QUICK PARSLEY FLAVOR** When you have lots of extra parsley, grind it and make ice cubes out of the juice. Wrap each cube separately in foil or in a baggie and store in freezer for flavoring soups, sauces, and gravies.

**PARSLEY SALAD DRESSING** Mix thoroughly together ½ c. buttermilk, 6 T. mayonnaise, 1 T. vinegar, ½ c. fresh chopped parsley, 3 T. grated Parmesan, and 3 minced cloves garlic. If it's too thick, add a little water until it's the consistency you want. Use for pasta and cooked vegetable salads, asparagus, and artichokes. It's also good spread on bread and broiled until the top bubbles and starts to get brown.

**PARSLEY TABOULI** Combine ½ c. soaked raw bulgur wheat, 3 chopped tomatoes, 1-1½ c. chopped fresh parsley, ½ c. chopped green onions, ½ c. lemon juice, ½ c. cooking oil (sesame or olive is best), 2 T. chopped fresh mint, ½ t. salt, and a pinch paprika. Mix well and let rest in fridge several hours. Taste. Add more seasoning if wanted. Optionally, add chopped black olives or other chopped greens.

**PATCHOULI (Pogostemon patchouli):** This is a shrublike mint from India. Its aromatic oil is a powerful perfume. Even in a temperate zone, you can grow patchouli if you dig it up, pot it, and bring it into the house for the winter. Available from Merry Gardens.

**PENNROYAL (Mentha pulegium):** A potentially deadly variety of mint, this semi-hardy plant prefers moist soil and has a low, creeping growing style, reproducing by runners. **NOTE:** Do not give pennyroyal to humans in any form or for any purpose. It contains a powerful abortifacient, which means it causes miscarriages, but don't take it for that purpose, because it also causes permanent liver and kidney damage and can cause death! In book after book on herbs I see pennyroyal tea recommended for something or other. That horrifies me. Please don't believe these books.

Pennyroyal is a fly repellent when planted around doors and windows because mosquitoes, ants, and fleas all avoid it. Powdered pennyroyal will take care of your cat's fleas. Available from Redwood City, William Dam, DeGiorgi, etc.

**PEPPER:** The familiar partner of salt is made from ground peppercorns, which grow on a vine (Piper nigrum) that thrives on the Malabar coast of India (and nowhere else!). Use whole, coarsely ground, or powdered.

For green peppercorns, harvest fruit while still unripe, soft, and green. Preserve them in salt water or vinegar, or dry in the sun. For black pepper, pick somewhat more mature berries and sun-dry until they turn black. For white pepper, let the peppercorns stay on the plant until they have a pink-red cast, which means they're fully mature. Then pick, pack in quantity, and let set until they ferment some. Then wash them well and dry. White pepper is milder than black. To most Americans, “pepper” means black pepper, but many European cooks prefer white pepper. It's good with gravies, vegetables, and soups.

**PEPPERMINT:** See “Mint.”

**PINEAPPLE SAGE:** See “Sage.”

**POKE SALET (ALSO CALLED POKE SALAD):** My friend Hazel, in Georgia, wrote me, “Poke salad is a wild plant with large dark berries which are poison. Gather in early spring around wet swampy places. Use the first tender green leaves. It's the first thing 'fresh' we can get around here so when we see it in the early part of the year, we know spring has arrived. The stems are good fried like okra.”

I've got another friend who loves poke salad greens. She's Violet Stewart, a woman of Native American descent from Okal, Oklahoma, who says ripe poke salet berries make a deep red dye. They are ripe in the fall. And the Native Americans in Oklahoma still use them to dye clay, wood, cloth, wool, and feathers.

Dee of Hopewell, VA, also of Native American descent, wrote to warn that poke salet leaves are also “somewhat poisonous—unless cooked a long time through several changes of water, more trouble than they're worth.”

**POKE SALET DUMPLINGS** Make dumplings with cornmeal. Shape into balls and drop into the pot of boiling poke salet. Be sure to use hot water for the dumplings. I've heard another way to fix poke salet greens is to mix them with mustard leaves, cress, or other greens. Add a dash of salt and some ham or bacon. Keep covered while cooking. Gardening in the South, a great book, has a section on poke salet.

**POPPIES:** There are numerous varieties. The California poppy (Eschscholzia californica) attracts birds who love its seeds, but it is entirely different botanically from the “poppy” whose seeds are used as a bread topping. That's a species of Papaver used since the Stone Age for the food value in its seeds. The seeds have a mildly spicy taste and are good used whole, pressed into the dough, to top breads, rolls, cakes, or cookies. Because one variety of poppy is also the source of heroin, a disgusted friend told me that one day Drug Enforcement Agency agents came stomping through all the front and back yards in her north Idaho neighborhood, yanking out every poppy they saw. (The seeds have no narcotic qualities; only the milky exudate from the opium poppy's green seed pod does.) Redwood City offers several varieties, including “Breadseed,” a good one for growing those baking seeds.

**Growing:** This plant is best adapted to a Mediterranean or southeast Asian climate. In northern zones the seeds won’t have time to mature in your garden unless started indoors. Plant in peat pots to avoid overt transplanting, which usually fails. Plant 6 inches apart in fertile, damp soil and full sun.

**Harvesting:** Let the seed pods ripen on the plant until that golden moment when they are fully ripe but have not yet turned their salt-shaker top openings toward the ground and dumped out the seed. Take the pods indoors to finish drying. When dry, thresh by rubbing between your palms.
Purslane (Portulaca oleracea): This Brassica relative is also known as puvpier, pursule, verdolaga, carti-choy, and portulaca. Purslane is a common weed in the United States and many other places. It can endure drought and thrive in any soil. It will reseed itself.

**NOTE:** Purslane is a risky plant to start in your garden. It has a powerful natural insecticide that grows up to 2 feet tall.

**Varieties.** Wild purslane has jointed, purplish-green stems and fleshy reddish-green foliage; it’s a creeper. The cultivated variety that Europeans have grown for hundreds of years grows taller; it has larger leaves that are golden yellow instead of reddish green. The cultivated French purslane has a milder flavor than the weedy wild one. Plant after frost danger has passed. Seeds for French purslane are available from William Dam and Le Jardin du Gourmet.

**Using.** Best to harvest before flowering, for after that stems get tougher. Use young shoots and leaves raw in salads, stems in pickle mixes, and leaves and stems in any cooked form. Purslane stems are thick and fleshy and, when cut, ooze a mildly acid fluid that will thicken a recipe much as okra does.

Pyrethrum (Chrysanthemum roseum): This perennial is a related species of insecticidal chrysanthemums. It is a powerful natural insecticide that grows up to 2 feet tall.

**NOTE:** Pyrethrum is poisonous to people. Do not eat it.

Pyrethrum blossoms are daisy-like and pink, white, or red. Propagate by root division or seeds. Plant in welldrained, slightly alkaline soil, in full sun. The plant gets about 18 inches tall. Plant them 1½–2 feet apart. To harvest, gather the flower heads and dry them. Make a spray of dried blossoms. The spray will repel soft-bodied insects such as aphids. The powder is a good flea control for your animals. Two varieties available from Redwood City.

Rose: These fragrant, hardy perennials grow 2–8 feet high. Most have thorns. Modern roses are more varied in color than wild or old-fashioned roses, but as hybridizers have moved the species toward more photogenic blooms, their fragrances have weakened and even disappeared in the process. The scentless rose is a modern reality. That’s why, to grow roses for use in potpourris, rose jars, beads, and food, you can’t start with just any of the vast variety of roses; you need an “old-fashioned” rose. (Lovers of old or new roses might enjoy American Rose Magazine, published by the American Rose Society. Annual dues are $37, Canadian $42, international $47, and include a subscription. Contact: PO Box 30,000, Shreveport, LA 71130-0030, 800-637-6534; ars@ars-hq.org; www.ars.org. They also offer a Handbook for Selecting Roses, in which members rate more than 3,000 commercially available roses.

**Old-Fashioned Roses.** The heritage roses are usually more winter hardy, more able to handle hot summers, and more strongly scented than the moderns. Patricia Wiley, owner of Roses of Yesterday and Today, reviewed this rose section, and made valuable corrections on my facts.

She added: “There are roses dating back to the time of Christ and before. An ‘old’ rose was discovered/introduced before the date of the first Hybrid Tea, which was La France. Most old roses are overpoweringly fragrant. The fragrance intensifies with drying the petals and buds. The old-fashioned roses vary in their bloom time. Some bloom only once in the spring, but there are many that bloom again and again throughout summer and fall. Much more interesting and lovely than the modern roses, each of the old roses has its own personality. Beyond the ease of care, there are many reasons for planting them: mass of bloom, fragrance, foliage color that varies from pale green to grey, and even leaves that change color in the fall of the year.

“Most old-fashioned roses shed their old bloom cleanly and do not have to be constantly clipped back. Just shape up the plant after it blooms in the spring and then leave it alone. Its beauty is in the large plant with masses of flowers. It should never be pruned severely.

“The most fragrant types of old roses are the Damasks, Bourbons, Centifolias, Moss roses, Albas, and Gallicas. Many hybridizers are bringing fragrance into the modern roses by combining them with the old roses for new varieties, so you must use your nose in discerning fragrance. Choose rose varieties with petals varying from deep pink to deep wine if you want to make the most colorful potpourri. The Hybrid Perpetuals are old roses of Grandma’s time and she called them ‘cabbage roses.’ There are many varieties of these roses, and most are very fragrant: ‘Paul Neyron’, ‘Heinrich Munch’, ‘Prince Camille de Rohan’, ‘American Beauty’, and ‘Henry Nevard’, all excellent for making potpourri, and all good garden roses.”

**Planting.** Buy young plants. Set out in a sunny, absolutely weed-free bed of somewhat heavy soil, with plenty of compost or manure worked in. Its best to plant early in spring, when the soil is no longer frozen. Water and add more manure or compost regularly, as the rose grows. Lay a thick mulch over the roots to suppress weeds, hold in moisture, and protect the roots through severe winters. Old-fashioned roses don’t need much pruning, just cutting away of dead wood.
Rose Sources
High Country Roses specializes in one-year-old old-fashioned and hardy roses (tested in Colorado at 8,000 ft.) grown on their own roots. They offer 200+ varieties, shipped in 1-qt. pots; free catalog: 800-552-2082; 435-789-5517; PO Box 148, Jensen, UT 84035; www.highcountryroses.com.

Jackson & Perkins calls itself "one of the foremost producers of new roses in the world," especially floribunda: 800-292-4769; www.jacksonandperkins.com; PO Box 1028, Medford, OR 97501.

Roses of Yesterday and Today does mail-order retail sales of old, rare, and unusual roses—more than 240 varieties; catalog $3; 831-728-1901; 803 Brown's Valley Rd., Watsonville, CA 95076; www.rosesofyesterday.com.

Susannah Garden & Nursery is an antique rose (and herb) specialist: 281-288-5835; 20120 Kuykendahl, Spring, TX 77379.

Using. The petals are the part of the rose where the fragrant oil for scent or flavor is concentrated, so that's the part you work with to make sachets or to flavor jelly, cake, etc. You can do more with roses than perhaps you ever guessed! But first let's consider the fruit of the rose, used not for its fragrance but for its huge vitamin C content.

Rose Hips. A rose hip (or "hep") is the round orange-to-reddish "fruit" (also called "haw") formed after the flower of a rose has bloomed. The hip is the seedpod of the plant. Some hips are better-tasting and bigger than others. Rosa rugosa, the Japanese rose varieties, flower with large and lovely blooms in almost every color. They also grow the largest rose hips, about 1 inch across, which are much easier to work with. Sweetbriar eglantine (Rosa eglanteria) also has good hips. The sweetbriars have the extra gift of aromatic leaves that smell like ripe apples and can be added to your potpourri. Wild rose hips are also good. There are wild roses in every state except Hawaii. The rugosas have escaped and gone native in some areas.

Rugosa Rose Varieties. These sucker profusely, so it's wise to plant in a big container or some other kind of root-limiting structure. Or buy grafted plants, so you don't get a forest of roses that takes over the yard. It isn't a good idea to plant them near wide open spaces either, because birds are likely to disperse their seeds and create thorny rugosa thickets out in your pasture. They do make a great 6-foot-tall, impenetrable hedge, the kind Sleeping Beauty had. They are easy to grow, exceptionally hardy, and can endure wind, seaside exposure and drought conditions (once established). They can be planted from seed in either full sun or partial shade and almost any well-drained soil. They have almost no problem pests or pestilences, and actually produce hips better with little to no pruning. Rugosa does need winter chilling and won't grow in subtropical climates. Rubro or eglanteria available from Gurney’s, Raintree Nursery, Farmer, Roses of Yesterday and Today, or High Country Rosarium.

NOTE: When picking rose petals or hips to eat, be sure they have not been sprayed by you or anyone else. Those growing along railroad tracks and major highways probably have been sprayed and should be avoided.

Harvesting Hips. Some people gather hips any time after they have turned from yellow to orange and on to scarlet. Some wait for the first frost, convinced they taste better after that. If allowed to get soft, they're definitely not nice anymore.

Processing. We're talking vitamins here. That means keep them cool until you can use or preserve them, and the sooner you do that the better—same day, if possible. Stew, dry, or freeze. Wash and cut off both ends of hips with scissors. Cover if you cook them. Use wooden spoons and earthenware or china bowls. Cook in glass or enamel pans or stainless steel. Hips are so high in vitamin C that they are valuable for winter use to supply that vitamin in tea, etc.

Cooking. Process into jelly; combine with honey to make a syrup; make granita, jam, extract, cold rose-hip soup, or hot tea.

Freezing. Just toss them into plastic bags and freeze until needed. Or make sugarless rose hip syrup by pouring boiling water to cover the hips and cooking on low heat 15 minutes. Let that cool and steep 24 hours. Strain and freeze. When needed, use your sugarless syrup to enrich soups, toppings, teas, etc.

Drying. For large hips, wash, cut open, take out seeds, spread, and dry in oven or dehydrator at 110°F until they are hard and brittle. For small hips, you can dry whole without cutting or removing seeds, or you can cut into slices and dry, also without removing seeds. When thoroughly dry, store in airtight jars. (If not very dry, they will mold.) When ready to use, cover with water and simmer until soft. Use the pulp to make jam or jelly. Hips mix well with other fruits like apple or cranberry.

★ ROSE HIP TEA. Boil dried coarse-ground rose hips with water, about 1 T. for each cup of tea. The longer you boil, the stronger your tea. Mash the hips with a spoon to get out all the juice, and strain. Sweeten with brown sugar or honey.

★ DORIS'S HIP MIX TEA. Rose hips are not strongly flavored, although they are nourishing, so a hip mix makes for a tastier tea. Stem the hips, dry them, and grind. Mix dried ground hips with mint and well-dried strawberry leaves: ¼ rose hips, ¼ mint, and the rest wild strawberry leaves. Or leave out the mint, or combine hips with lemon balm, etc.
ROSE PEAR GRANITA This recipe is from Lane Morgan’s Winter Harvest Cookbook (Sasquatch Books, 1990), an excellent little collection of gourmet recipes for homely vegetables that you might have in your field, garden, or root cellar in the winter. “No special equipment is required for this simple ice from Le Gourmand. The rose hips give the crystals a bit of tartness and a gorgeous red-gold tint. This makes a good digestive as well as a deceptively simple dessert. 1 quart pear juice. 1/2 cup rose hips, cut in half and seeded. Pour juice into a saucepan, add rose hips, and simmer, covered, until liquid is reduced by half. Put through a food mill and pour into a shallow pan. Freeze. Stir when mixture starts to get slushy and return to freezer until time to serve. Makes 1 pint.”

ROSE HIP SYRUP Wash 2 lb. fresh hips and remove stems. Put through food chopper using medium blade. Cover with 6 c. boiling water and boil 2 minutes. Strain through sieve and put solids in a jelly bag to drain. There should be 1 1/2 pints of liquid. If more, boil it down. Add 3/4 c. sugar and boil for 5 minutes. Bottle.

ROSE HIP JAM Try to preserve the hips the same day you pick them. Boil 4 c. hips with 2 1/2 c. water until the hips are tender. Put through sieve to remove seeds. Add 1 c. sugar for every 2 c. pulp. Add 1 t. lemon juice. Mix thoroughly and bring slowly to a simmer. Cook about 20 minutes. Seal.

ROSE HIP EXTRACT From Lila Morris, Beavercreek, OR: “Add it to breakfast juice, gelatin, desserts, meat sauces, soups or sherbet for lots of vitamin C. Gather rose hips, chill, and remove blossom ends, stems, and leaves. Rinse off. For each 1 c. hips bring to a rolling boil 1/2 c. of water. Add the rose hips. Cover and simmer 15 minutes. Mash with fork or potato masher and let set 24 hours. Strain off liquid part. That’s your extract. Bring extract to a good boil. Add 2 T. vinegar or lemon juice for each pint. Pour hot into jars and seal.

ANN MARIE’S EXTRACT For each 1 c. hips, pour over 1 c. boiling water. Let soak 48 hours. Strain off the juice. Add 1/4 c. honey per quart of juice. Heat to boiling point. Pour into deep hot jars and seal. Take 2 t. per day in winter for your vitamin C.

ROSE HIP JELLY Wash, stem, and chop your hips. For every 4 c. hips, boil 2 c. water for 5 minutes and then let hang overnight in a jelly bag to get the juice. For every 1 c. rose hip juice, add 3 c. apple juice. Boil 10 minutes. Gradually add 1 c. sugar for every cup of juice you are working with, and boil until it jells.

Harvesting Rose Petals. Gather just when the rose has fully expanded. If you wait a day longer, until they start to fade, they will have lost some of that precious fragrance. Gather in the morning after the dew has dried, but before they have gotten really warmed by the sun. Dry before proceeding by pressing them gently between layers of cloth. Dry them in a dehydrator or on a muslin cloth laid over a screen in an airy, shady place.

ALL-ROSE Potpourri This potpourri has a prettier color, but it doesn’t stay near as fragrant as long as the moist one. Gather your fragrant roses in the early morning just after the dew is off. Use roses between three-quarters and full bloom. Simply hold petals together with the tips of your fingers and twist. They will usually all come off in your hand. Gather small buds too. Dry your petals and buds on a screen or cloth or in a dehydrator, out of direct sunlight. When dry, combine with powdered orris root and set out in an open-topped jar. Or use in a sachet.

A DAMP POTION Save dry the rose petals just until they feel leathery—8 hours or overnight. Use ice cream-type salt that is coarse and not iodized. Layer salt and rose petals in the bottom of a glass jar, 1/4 c. salt to 2 c. petals. Add some orris root, too. Keep a lid on the jar and open only when you want to let out some fragrance.

ATTAR OF ROSES “Attar” is rose petal oil. The damask rose varieties (Rosa damascena) are good for making attar. I’d heard that Rosa damascena trigintipetala is the most highly regarded variety for making potpourri and attar. But Patricia Wile says the best is Rosa damascena bifera, the rose of Castile. Pure attar of roses is extracted from fresh petals. The finest potpourris are made by spraying attar on dried, mixed petals and buds.

Fill a large glass jar with rose petals, carefully separated from the rest of the plant. Add just enough water to cover them and let the jar set in the sun 2–3 days, bringing it indoors overnight. At the end of the second or third day, small particles of yellow oil will be floating on the surface of the water. In the course of a week, they will have increased to a thin scum. The greenish-yellow scum is attar of roses. Take it up with a little cotton tied to the end of a stick, and squeeze it into a small container. Or use a feather. On the commercial market, attar of roses is very pricey stuff, a valuable ingredient of perfumes. It takes a whole lot of roses to make even a tiny bit of attar: approximately 5 lb. of petals for 1 oz. of oil.

ROSE EXTRACT Put petals into a wide-mouthed bottle and pour over them some pure alcohol. Let stand a month, and then strain. The liquid is rose extract, or essence of roses.

ROSE WATER Combine 1 part attar with 1 part alcohol and 10 parts distilled water. Or 1 t. extract mixed into 1/4 c. distilled water. Or combine 1 oz. attar with 1 gal. distilled water. Age 2 weeks. You have to shake a long time, slowly at first, to get a solution.

ROSE BRANDY To flavor sauces for cakes and puddings, gather rose petals while the dew is on them. Fill a bottle with them. Then pour into the bottle a good brandy. Steep 3 to 4 weeks. Strain and re-bottle.

ROSE VINEGAR Boil 2 c. white vinegar in non-aluminum pan and pour over 1 c. rose petals. Add 1/2 t. lavender or rosemary. Cover and steep 10 days. Strain and bottle. Patricia Wile wrote me, “You can use 2 cups vin rosé wine for a light wine vinegar—pretty, too!”

ROSE PETAL HONEY This recipe was a favorite of Martha Washington’s. Bring 2 pints of honey to a boil. Add 1 pint rose petals. Let stand 4 hours. Heat again. Strain into jars.

ROSE PETAL JAM Chop the petals into pieces and pack firmly into a measuring cup. You’ll need 2 cups for this recipe. Cover the 2 c. petals with 2 c. boiling water in a pan and simmer for 10 minutes. Strain, keeping the liquid. Add 2 1/2 c. sugar and 3 T. honey to the water in which the petals were
cooked. Simmer, uncovered, for 30 minutes. Add 1 t. lemon juice and the chopped petals, and simmer 30 minutes more. The rose petals will have dissolved. Have ready your clean, hot jelly jars. Pour hot liquid into the hot jars and seal.

**SARA’S ROSE PETAL JELLY** Corean Morgan, Sweet Home, OR, wrote me about her friend Sara, “Dear Carla, The recipe book I bought has been given to a friend—who lives on top of Green Peter Mountain, and who shot a bear (a real, live bear) that was getting honey from the hives. Not only did she shoot it, she skinned it and put both hide and meat into the deep freeze. Perhaps you would like to have this recipe of hers:

> “Combine 2 qt. pink rose petals, 3 c. boiling water, 3 c. sugar, ¼ c. lemon juice, and 1 package MCP pectin. Gather rose petals in early morning just after the dew has left. Yellow petals may be added if you are short of your quarts. Red rose petals may also be used, but be careful, since they have a much stronger flavor. Pour the boiling water over the petals and steep until all color is absorbed. Measure sugar into a dish to add later. Measure rose water and lemon juice into a 6- or 8-qt. kettle. Add pectin and stir well. Place on hottest fire and bring to a boil. Add measured sugar and mix well. Continue stirring and bring to a full rolling boil. Boil exactly 2 minutes. Skim and pour into prepared glasses and seal.”

**ROSE PETAL BREAD** Add to a regular 2-loaf white bread recipe 1 c. lightly packed rose petals, 1 t. rose extract, 3 t. lemon extract, and extra sweetening.

**PETAL-SCENTED TEA** The Chinese use cabbage rose petals and/or jasmine flowers to float on and scent a cup of steaming tea.

**ROSE AND RHUBARB SYRUP** Simmer 1 ½ lb. chopped rhubarb about 20 minutes. Strain. It’s the liquid you want to save. To that rhubarb juice add 1 lb. sugar and petals from about 8 red roses. Simmer 20 minutes more. Strain again, this time discarding the rose petals. Bring the syrup back to boiling. Simmer until it thickens. Pour into small (for it will ferment soon after opening) hot bottles and seal them. To use, add to a milk shake for flavor or to hot water to make a tea.

**CRYSTALLIZED ROSE PETALS** From Catherine Shirley: “I pick a few first roses. They are dark pink fragrant ones of the old-fashioned kind. They have thorns. This project is rather tedious and time-consuming, but makes nice gifts when put in nice containers at Christmas time. They are also pleasant to eat. I picked a few roses with short stems. This makes the roots get stronger. I cut off the white part, which is the base of the rose, because it is bitter. I take the petals apart and wash each carefully under running water; if water is not plentiful, I swish each petal in a pan of water and change the water quite often. Put on paper towel to dry. Then take an egg white, add a little cold water, and beat slightly. I dip each petal in the egg white, lift it out with a fork, and lay on granulated sugar, press gently, and carefully turn it over and treat same way and lift and lay on piece of waxed paper. Let dry thoroughly, turn over, let other side dry thoroughly. Then pack in a dark jar so they will keep their color. P.S. I make crystallized pinks or carnations called ‘pinks,’ and they taste nice, like clove-flavored candy.”

**ROSEBUD ICE CUBES** Freeze a tiny rosebud in each cube to float in special summer drinks.
pot for the winter, or keep potted all the time (start in 6-inch pot), for it does fine on a windowsill. Or keep in a 12-inch container outside in the summer and inside in the winter. Do note that dry indoor heat will cause leaves to drop.

**Planting.** You can propagate by seeds, but they germinate so slowly and unreliably that stem cuttings are preferable. Spring cuttings can be started in water and then planted. Or take cuttings of non-flowering shoots in early fall and plant in a cold frame to get through the winter. Or layer. Plant in well-drained, alkaline (add lime regularly), light soil in full sun, but sheltered from cold winds. Rosemary can handle dry conditions, but it needs at least several deep waterings each summer. Plant the upright species 12 inches apart. You can dig up and divide an older plant. Two or three will be enough to meet a family’s needs. It handles pruning well.

**Harvesting.** Pick rosemary needles anytime to use fresh.

**Drying.** Pick needles that are mature enough to have developed aroma but still relatively young and tender. You can cut foliage several times a summer. Remove poor-quality needles. Don’t wash. Spread thinly and dry in shade or slow oven/dehydrator at 110°F to crispness. Crumble before using.

**Using.** Called “the herb of remembrance,” rosemary has been used both at weddings to symbolize fidelity and at funerals, placed on graves, to signify remembrance. More mundane uses: in perfumes, as a hair rinse (leaves hair scented and shining), in potpourri, as an insect repellent where food and clothing are stored, and, of course, as a fresh or dried seasoning for food (a little goes a long way). Pluck some needles to add to boiling potatoes, summer or winter squash, turnips, sautéed potatoes, and add to soup. The leaves make a good herb tea. Rosemary leaves and cranberry juice combine for a good herb jelly.

**HERBAL HAMBURGER** Melt 1 T. butter with ½ t. dried rosemary in a frying pan. Stir a bit to let rosemary flavor butter. (Don’t brown butter.) Add about 1 lb. hamburger shaped into patties, and cook. Remove hamburgers when done. Add another 1 T. butter to pan drippings together with ½ t. dry mustard and a dash Worcestershire sauce. Stir a minute. Pour over hamburgers.

**ROAST POTATOES WITH ROSEMARY** Use 2 lb. really fresh new potatoes, scrubbed and cut into 1-inch cubes. Preheat oven to 425°F. Place potatoes, leaves from 4 large sprigs of fresh rosemary, and 4 large cloves of peeled and crushed garlic in a roasting pan. Pour ½ c. olive oil over that. Sprinkle in salt and pepper. Now bake, stirring occasionally, until potatoes are browned and crisp on the outside, tender and sweet on the inside, 30–40 min. Sprinkle with parsley and serve. From Winter Harvest Cookbook by Lane Morgan.

**ROSEMARY TEA/HAIR RINSE** Pour boiling water over the needles, and steep until to your liking.

**RUE:** Do not drink or eat this plant; it is toxic. Propagate by stem cuttings or seeds. Plant in well-drained, light soil in full sun. The plants are only a foot high. Both the stem and leaves can be used. Rue is ignored by the Japanese beetle. Its smell is unpleasant. In hot weather, handling rue can cause poison-ivy type blisters on sensitive skins. Use only as an insect-repellent or decorative plant. Available from William Dam, DeGiorgi, etc.

**SAFFRON (CROCUS SATIVUS):** This strongly aromatic crocus gets only 4–6 inches high. It has thin, grasslike leaves. It’s easy to grow, but takes 3 years to produce flowers from seed, so it’s much quicker to start with plants, propagating by planting divisions of “corms” (enlarged underground stems) called “offsets” in late summer.

**NOTE:** The autumn crocus (Colchicum autumnale) resembles saffron crocus but is not a true crocus and is poisonous.

**Planting.** Plant 3 inches deep in rich, well-drained soil, full or partial sun, 3 inches apart, outdoors (zones 6–9) or in a container. Saffron corms available from Nichols Garden Nursery.

**Harvesting.** The saffron crocus develops purple flowers in the fall. Saffron is the most expensive spice because of the effort, tedium, and small return of harvesting the red-orange, edible stigmas—the “threads” at the center of the flower. Gather the stigmas using tweezers. Dry them in a warm and airy but shaded place. You can buy either ground saffron or whole dried stigmas or “threads.” It’s safest to get the threads because ground saffron may well be adulterated.

**Using.** Saffron colors sauces (or dyes fabrics) a golden shade and adds a unique flavor to foods. It is essential for making bouillabaisse, Spanish rice, paella, and saffron breads.

**SAFFRON, MEXICAN:** This is an imitation sold in some Latin American outlets; it’s made of dried, ground safflower petals. For more information, see Chapter 4.

**SAFFRON COLORS SAUCES (OR DYES FABRICS) A GOLDEN SHADE AND ADDS A UNIQUE FLAVOR TO FOODS. IT IS ESSENTIAL FOR MAKING BOUILLABAISSE, SPANISH RICE, PÆLLA, AND SAFFRON BREADS.**

**SAGE:** This herb is a semi-hardy perennial that grows to 2 feet high and has light-blush flowers. It has numerous varieties—narrow-leaved, broad-leaved, purple- and re-leaved, and dwarf, which is good in a pot. (For information about the fragrant sagebrushes of drylands in the western United States, see “Artemisia.”)

**Broad Leaf Sage (Salvia officinalis).** This is the historical medicinal variety, but it can also be used at table. It’s a perennial that needs direct sunlight. Available from DeGiorgi.

**Clary Sage (Salvia sclarea).** This 3–4 foot biennial is valued for both its attractive, aromatic flowers and its use as a fragrance fixative like orrisroot. It originated in the Mediterranean. Plant seed every year to get flowers. Plant in full sun and average soil. Plant outdoors 1 foot apart, or in shelter and transplant later. Clary sage leaves are used fresh to flavor drinks and egg dishes. Dried leaves are good with rose petals, lavender, and mints in potpourris or sachets, or added to soups or stews. Dried clary sage leaves make a fine herbal tea. Clary sage seeds, like quince seeds (see Chapter 6 for recipes), release a mucilaginous material when soaked in water. This paste was traditionally used to bathe eyes. Available from Redwood Seed.
Pineapple Sage (Salvia elegans). This is a tender perennial, the last herb of the season to bloom. You can add its red flowers to fruit punch or salads for a pretty color and a nice fruity flavor. The leaves are edible too, and have a mild pineapple flavor. Use them in fruit dishes and to make an herb jelly. This plant has to be transplanted to a pot and brought inside to survive a real winter. It is different from scarlet sage, which is an inedible ornamental.

**Planting.** Sage grows easily from seed and transplants easily. Seed is easy to find and is viable for 2–3 yrs. Or use stem cuttings, or root division in the early spring. Fine in average-to-poor, well-drained soil (let dry between waterings) and full sun. Plant 2–3 plants for family use in 6-inch pots or a foot apart in the garden. Plant it away from your annuals, since it will inhibit their growth. Broad-leaved sage and clary sage freely self-sow. Because sage grows well in a pot, some people bring it in for the winter. Too much fertilizer or water weakens the aroma of the leaves. In the spring, prune away the old, dead, woody parts, or thin by removing 3–4-year-old plants because of their developing woodiness. Sage naturally dies after about 5 years.

**Harvesting.** If you want just a few leaves, go out and pick them anytime after your plant is 8 inches high. The best leaves are newly grown from the tips of the branches, or stems, cut just before flowering. But you can cut off whole stems to dry even at the last moment in the fall, and they'll definitely be sage. Sort them over. Don't wash. Tie in bunches and hang up to dry, or dry in the sun, dehydrator, or very slow oven at 110°F until crisp. Sage has a dryish quality even on the plant, and once dried, it stays dry. To store, rub off the stems and pack into airtight jars.

**Using.** Chopped fresh sage leaves add flavor to pickles, cheese, and sausage. Dried sage is best in poultry or pork stuffings; if you are using fresh sage, soak it 5 minutes in boiling water, dry, and then chop.

**SAGE BREAD** This is a good sandwich bread. If your milk is raw, scald it first. Use 2 c. milk, ¾ c. sugar, 2 t. salt, 2 t. celery seed, and 1 t. powdered sage. Add ¼ c. cooking oil, 2 eggs, and 2 T. yeast. Mix well. Add enough flour to make a kneadable dough. Knead, let rise, punch down, and divide into 2 loaves. Put loaves into greased bread pans, and let rise again until they double in bulk. Bake at 400°F until loaves sound hollow when rapped.

**SAGE TEA** Steep fresh sage leaves or 1 heaping t. powdered sage in 2 c. boiling water. Strain. Sweeten to taste. Drink hot. For a medicinal gargle, brew until dark green in color. This is a traditional comfort for the cold victim as well as a good hair rinse.

**SALAD BURNET:** See “Burnet.”

**SALT:** Salt is sodium chloride. Just ⅛ t. salt per day is necessary to keep you alive. But too much more of it day in and day out will give you high blood pressure and put you at risk for stroke and heart disease. A person who does little physical labor and spends the summer in an air-conditioned office doesn't need much salt. However, if you spend your summer days working hard out in the sun, and in the evening come home to a hot house, you need as much salt as you hunger for as well as plenty of water or diluted, unsweetened fruit juice to compensate for all that perspiring.

The secret is not to let salting become a habit, because salt needs vary according to the time of year and your activity. In the old days salt was used to preserve food, but now there are healthier ways of preservation. Most foods naturally contain sodium, as do some water supplies. Almost everybody in a grocery-store, restaurant-eating lifestyle gets too much salt in their diet.

**How to Lower Your Salt Intake**
1. Don't salt your cooking water.
2. Don't eat “processed” foods. Cook from scratch so you can leave the salt out of the recipe (or greatly reduce it). The worst offenders in the grocery store are canned soups, lunch meats, canned vegetables, and all “snack” foods. Fast-food restaurants typically serve high-salt meals, and virtually all restaurants use some salt.
3. Avoid beets, carrots, shellfish, cheese, and celery, because those foods are naturally high in sodium.
4. To flavor your food, use herbs, spices, flavored vinegars, wine, and garlic instead of salt. Thirty-year-old Ruth, doing her best to wean me entirely from the salt habit, advised me, “Try things like finely chopped onion, tomato chunks, sweet pepper, lemon juice, and various herbs instead of fostering that salt taste. There is such a thing as low-sodium tamari, but don't become dependent on that either.”

And read *Cooking Without a Grain of Salt* by Elma W. Bagg (1971).

**SASSAFRAS:** Do not eat products made with sassafras bark or root. The sassafras tree can be grown in mild climates like Texas and Arkansas. The leaves are made into file, a traditional gumbo ingredient. In the past the wood, root, and bark have all been used to make beverages; however, the FDA has taken the bark (which was an old-time root beer ingredient) off the market because of its risk as a carcinogen.

**File.** Pick young, tender sassafras leaves in the spring. Spread over your drying surface and dry outdoors in an airy, shady place or in oven or dehydrator at 110°F until they are crisp. Then pulverize them to make your file powder. When added to soup (gumbo), they give it a distinctive flavor and have a thickening effect. Note: Never boil the gumbo after adding the file powder. If you do, it becomes ropey, stringy, and disagreeable. For this reason, reheating leftover gumbo can be a problem, so just make enough for 1 meal at a time.

File Variations—Mix file with a few leaves of sweet bay. Or, if you don't have sassafras, substitute young okra pods for the file.

**SASSAFRAS BEEF GUMBO** Add 1 large spoonful of dried and powdered sassafras leaves to a pot of beef soup after taking it off the heat.

**FROM-SCRATCH OLD-TIME SASSAFRAS GUMBO** Start with 6 squirrels or 2 chickens. Cut up small and cook until flesh falls from bones. Add 1 qt. okra, 2 onions cut fine, 6 diced white potatoes, grated carrot, a little cabbage, pepper, and salt. Add pod of red pepper and file just before serving.

**SAVORY:** There are 2 basic varieties of savory, summer savory (Satureja hortensis) and winter savory (Satureja montana). They are used the same way in cooking. Both grow fine in a pot. Both attract bees, prefer full sun, do well in poor, stony soil, and prefer soil to dry out between waterings. But they have significant differences.

**Summer Savory.** This savory is an annual that gets about 18 inches tall and is grown from seed planted in the early
The leaves of both types of savory have a peppery quality that goes well in salads, soups, and sauces. Dried leaves are good in poultry stuffing and with meats, fish, cheese, eggs, and green beans. It's also used in sachets. Crushing and rubbing summer savory leaves on a bee sting can help make it better.

**SESAME (Sesamum indicum):** This annual does best in full sun, grows to be about 2 feet tall, and blooms with pretty trumpet-shaped white flowers. In late summer the flowers wither and a seedhead develops that contains the small nut-flavored seeds we know as sesame seeds. These must be harvested before fully mature; otherwise, they will shatter onto the ground. Use fresh or toasted.

**SLIPPERY ELM:** Old-timers would break the inner bark of slippery elm into bits to make the famous tea. They would pour 1 c. boiling water over 1 t. slippery elm bark and let it steep until cold. When cold, it was strained, and lemon juice was added to sweeten it to taste. But since the elms are high to be about 6 inches apart. Summer savory's flavor is sweeter and finer than that of winter savory. Available from Redwood City, Thompson & Morgan, DeGiorgi, and William Dam.

**Winter Savory.** This hardy perennial survives down to 10°F with mulch and a sheltered position. Compared to summer savory it's a little smaller and much prettier, with its little lavender summer flowers. Winter savory seeds are so slow to germinate that it's easier to propagate them via cutting or root division in the fall. Grow in 6-8-inch pots, or plant 1 foot apart outside. The flavor of winter savory leaves is similar to but stronger than that of summer savory. One plant is enough. It will die after 5 years, so figure on replacing it. Available from William Dam and DeGiorgi.

**Harvesting and Drying.** The flavor is strongest when the plants are in flower. Summer savory leaves can be harvested in mid-summer or can be pulled out by the roots in the fall for drying. Winter savory tips can be cut 2 or 3 times a summer. Don't wash. Dry in shade or at 110°F Done when crisp.

**Using.** The leaves of both types of savory have a peppery quality that goes well in salads, soups, and sauces. Dried leaves are good in poultry stuffing and with meats, fish, cheese, eggs, and green beans. It's also used in sachets. Crushing and rubbing summer savory leaves on a bee sting can help make it better.

**Sorrel:** Sorrel originated in Eurasia. The variety called garden sorrel now grows wild in many places in the United States. All true sorrels are very hardy (zones 5-9) perennials, members of the buckwheat family. They all have a similar taste and can be used as leafy flavorings for salads and meat, fish, or egg dishes. 

**NOTE:** Oxalis acetosella or wood sorrel, although it has a similar name, is not related and is not safe to consume!

**Varieties.** There are several true sorrel varieties, wild and domesticated. The preferred eating kind, French sorrel or oseille, is easily confused with its wild relative, sheep sorrel. The various sorrels are also known as sourgrass. The other domesticated sorrel is garden sorrel or Grande de Belleville (Rumex acetosa). Its leaves get up to 2 feet long, compared to the 6-inch French sorrel. Available from DeGiorgi.

**Sheep Sorrel (Rumex acetosella).** Also known as dock, this is a common weed. It is related to, looks somewhat like, and is as delicious as French or garden sorrel, and it can be used in exactly the same way. But I don't recommend letting sheep sorrel into your garden, because it propagates by underground runners (like morning glory) that tend to be terribly difficult to control in the garden. If you want a sorrel, plant French or garden instead. If you must plant sheep sorrel, do so inside outer barriers that will safely stop those roaming roots from taking over.

**French Sorrel (Rumex scutatus).** This one propagates slowly by developing clumps on its perimeter (which you can divide and move) as well as by seed. In fact, it's a good idea to pinch off all developing seed heads, for French sorrel will self-sow and can become a weedy garden nuisance in that way. Pinching off seedheads also keeps its energy going into making leaves for flowering and cuts way back on, or even ends, leaf production. Still, French is more controllable than sheep, and that's why it's the sorrel variety of choice for gardeners. Available from DeGiorgi, etc.

**Planting.** French sorrel prefers somewhat acid soil and does not grow in quite alkaline soil. Being perennial, it needs a permanent location and appreciates nitrogen. If you have scorching hot summers, choose a site with partial shade. If your summers are frequently cloudy, plant in full sun. Otherwise, it is easy to grow, a bush that will become between 18 inches and 3 feet high. Once started, it will basically make it on its own, although it produces leaves best in moist soil. Sorrel has relatively deep roots and so can handle dry spells better than some other plants. Plant from seed in March or by root division, directly outdoors, in either spring or fall. Plant ½ inches deep in 6-inch pots or outdoors a foot apart. Keep the dirt moist until the plants appear. Thin to 6 inches in a dry climate, 12 inches in a wet one. French sorrel runs out of "oomph" and needs to be divided, moved, or given generous nitrogen feedings at least every 3-4 years. Wherever sorrel has been growing, the nitrogen will be depleted. Sorrel has a chronic problem with Japanese beetles.

**Harvesting.** French sorrel will be the first green to appear in your spring garden. The arrow-shaped leaves can be harvested in spring, fall, and winter. Choose fully formed leaves, 3-7 inches long. Take only the outer leaves so the rosette heart will be undamaged and able to continue growing new ones. Harvesting those outer leaves, whether or not you need them, is desirable because it keeps the tender new ones coming. Basically, you harvest in spring, give it up for a while in summer, and trim back the dense summer growth around September; then you'll get a fall crop of tender leaves that continue to come until a really heavy freeze stops them for the winter.

**Preparing.** Discard tough, overmature leaves, unless they're to be pureed. Sorrel wilts unusually quickly, as greens go, and must be moved promptly from garden to table. If you're harvesting sorrel for a cooked recipe, pick lots, because it shrinks! And never cook sorrel in aluminum or iron pans, because the sorrel leaves will turn an unappealing brown or even black. Carefully rinse off and drain the leaves.

**Sorrel Recipes.** The leaves have an acid, lemony, tart flavor that is surprising and pleasant in small quantities—when
Slivered thinly and added to the milder lettuce-type greens of a salad, for instance, or used like parsley to garnish fish or tossed in to help flavor a soup. Or use some chopped sorrel with your favorite other ingredients (tomato, cheese, etc.) as an omelet filling. Or blend with mayonnaise for added zip and green coloring. But sorrel is one of those plants that is high in oxalic acid, a substance that both prevents calcium uptake in your system and in quantity is a carcinogen, so it's best used sparingly (unless well cooked before use, which totally disarms it).

In larger quantities, sorrel's strong flavor can be disagreeable unless covered, as in a cream soup recipe, or heavily balanced, as in combination with fish, chicken, or game. For example, sauté sorrel with butter and chopped olives and serve with fish. Or cut the sorrel into small pieces, cook with trout or salmon, and serve with a white sauce or lemon juice. Or purely 1 lb. sorrel, combine with shredded, cooked chicken and chicken stock, and serve with lemon juice or cream. Or sprinkle chicken or fish with lemon juice and basil or pesto, wrap it inside large sorrel leaves, and bake.

**Southernwood (Artemisia abrotanum):** This close relative of wormwood is a decorative perennial bush 2–3 feet high with small yellow flowers in late summer. It’s not hardy and needs a sheltered planting where severe frosts won’t affect it. Plant in full sun in well-drained, heavy soil. Propagate by seeds or semi-ripe summer stem cuttings. Southernwood leaves are insect repellent and can be made into mothproofing sachets to be stored with clothing. They’re also used in potpourris. Because they taste so bitter, they are not used in the kitchen. Harvest and dry sprigs as you would wormwood.

**Stevia (Stevia rebaudiana):** Also called "myrrh," this perennial herb has ferny foliage, grows 2–3 feet high, and is a serious self-sower that can become a weed in your garden.

**Planting.** Plant the black seeds in fall or spring, or root pieces with a bud on each. Sweet cicely thrives in light shade and any type of damp soil. Allow 8–10 square inches per plant. Seedlings can be transplanted. To save your own seed, note that seeds should be chilled in damp peat for about 2 months (at least 40°F) for good germination. Seeds available from Thompson & Morgan and De Giorgi.

**Harvesting and Using.** It’s best not to harvest the first year unless you plan to treat the plant like an annual and expect it to die off at summer’s end. The plant parts all have an anise scent and flavor. Use leaves in salads and desserts. Sweet cicely can be cooked with very acid fruits like rhubarb and gooseberries. It sweetens any food it’s cooked with, reducing the need to add sugar, and is thus favored by diabetics. Harvest and preserve leaves as you would dill. The seeds have a spicy taste. Pick while still green, after the flowers fade. The taproot is remarkably large and can be cooked and added to salads or used as a vegetable.

**Tansy (Tanacetum vulgare):** Do not eat tansy. This medieval herb is now used only in dried arrangements and as an insect repellent. Propagate by seeds or plant division; it can be transplanted. The problem is usually over-propagation; tansy can become a problem weed in your garden, especially its running roots, which you have to constantly pull out to keep the plants from taking over the entire garden. Plant in average, well-drained soil, in full sun, about 3 feet apart. Available from De Giorgi.

Tansy in various forms, especially the oil, has been effective against flies, mosquitoes, ants, and some intestinal worms. It was used in the middle ages to flavor puddings, cakes, and in medicinal teas, to scent cosmetics, and to make perfumes, but it is now considered poisonous.

**Tarragon:** Originally from Siberia, tarragon is a perennial that comes in 2 basic varieties. French (also called German) tarragon (Artemisia dracunculus) is called “little dragon” for its pungent taste. It is not very hardy; if your winters are severe, mulch or bring in. It is a smaller plant (2–3 feet) that is most difficult to propagate, since it never makes seed, but is better tasting.

Russian tarragon (Artemisia dracunculoides) grows to 5 feet tall and will make seed, but it has poorer flavor. It’s preferred only where French can’t make it. Available from De Giorgi.

Note: Mexican tarragon (Tagetes lucida) is a perennial marigold whose leaves have a distinctive tarragon flavor and can be used as a substitute. Available from Redwood City.

**Planting.** Because French tarragon produces no seed, propagate it by layering, stem cuttings, or root division in the early spring (divide before growth is 2 inches tall). Plant in well-drained, fertile, light, sandy soil, in full sun or semi-shade. Divide large plants every 2–3 years. Grows well in a pot (use part sand).

**Harvesting.** Cut off fresh leaves any time through summer.

**Drying.** Cut off leaves and tops of young plants just after their dew has dried. Dry away from sun or in oven or dehydrator at 110°F until crisp. Or harvest whole stalks in early fall by cutting them off several inches above the ground and hanging them loosely to dry.

**Using.** A favorite with French chefs for its wonderful flavor, fresh tarragon leaves are good in oil and vinegar salad dressings and with beets, sauces, and any meat, seafood, or cheese. Also used to make perfumes. Dried tarragon is good in tomato juice or any tomato dish. If you’re using Russian tarragon, use more, since its flavor is weaker. Juice and fresh tarragon make a good herb jelly. You can sauté tarragon leaves in butter or oil and baste meat or poultry with it.

**Tarragon Eggs** A mixture of finely chopped tarragon, onion, and parsley is good in an omelet or scrambled eggs.

**Tarragon Vinegar** Tarragon keeps its flavor better if preserved in vinegar rather than dried. Gather the tarragon just before it blossoms. Discard the larger stalks. Mash the leaves some. For a plain tarragon vinegar, place 2 small sprigs of fresh tarragon in 2 c. white wine vinegar. Or make a fancy one by combining 4 c. tarragon leaves and smaller stalks, 1 qt. white wine vinegar, 3 cloves, and 1 small clove garlic (remove garlic after 24 hours). Takes 2 months to get really good.
**Thyme:** This popular, semi-hardy, low-growing (to 4–12 inches) Mediterranean perennial has a host of varieties. Common thyme (*Thymus vulgaris*) is easily grown, 6–12 inches tall with grey leaves and lavender blooms, great in the kitchen, can be used for fragrance, makes exceptional honey, and is an antiseptic. Lemon thyme (*Thymus citriodorus*) grows 4–12 inches high, has green leaves and lavender blooms, is good in salads, is superior for poultry stuffing, but is not as hardy as common thyme. Other types such as dwarf thyme and creeping varieties are grown as ornamentals and used in perfumery, but for kitchen use, what you want is common or lemon thyme. Almost every seedhouse carries one or more kinds.

**Planting.** Thyme grows slowly, so you're best off starting with a plant. Or plant seeds (viable for 2–3 years) in spring. Plant either indoors (1–2 plants per 4-inch pot, or 3–4 plants per 6-inch pot) or out—good in a rock garden or as a border—slightly alkaline soil. Thyme can handle full sun or part shade. Poor soil and infrequent watering actually improve the flavor. You can easily propagate creeping varieties by cuttings in spring or summer, or by root division or layering of lower branches starting in the second year. Thyme grows well in a pot. Bring in for the winter if weather is harsh. Creeping kinds are nice in a hanging basket.

**Harvesting and Preserving.** Snip some off and use fresh as seasoning, or dry for future use. Thyme is the easiest herb to dry, dried thyme is as effective as fresh, and harvesting makes your plant more bushy and attractive. If you are harvesting from an outdoor, creeping variety, wash the thyme thoroughly, because it tends to contain dirt. If harvesting from common or lemon thyme, which are bushy, cut down as far as the stem remains tender, and you won't need to wash it. Harvest anytime for fresh use. To preserve, cut when thyme has flowers, but snip only the non-flowering shoots. Dry at 110°F until crisp.

**Using.** The dried leaves are a seasoning ingredient for many soups and sauces, the herbal equivalent of pepper. You can make tea from the dried leaves or flavor vegetable juice, meats, soups, peas, poultry, clam chowder, and gravies. Use fresh leaves in salads. The only rule is to go as far as the stem remains tender, and you won't need to wash them. Harvest anytime for fresh use. To preserve, cut when thyme has flowers, but snip only the non-flowering shoots. Dry at 110°F until crisp.

**Tobacco:** Check with your local USDA and U.S. Treasury Dept. (Bureau of Alcohol, Tobacco and Firearms) so you can comply with any rules or regulations regarding the cultivation, production, or manufacture of tobacco or tobacco products before planting any tobacco seeds. *Nicotiana* species are one of the great natural insecticides. Just keep in mind that it's highly addictive, and don't smoke it. Redwood City sells 3 varieties as well as copies of an 1892 USDA instruction booklet for tobacco cultivation. You can buy seeds from Southern Exposure, Hudson, Seeds of Change, Native Seeds/SEARCH, Eden Organic Nursery (954-455-0229; www.conseed.com), or Jim Johnson, 3421 Bream St., Gautier, MS 39553. Virtual Seeds Co. offers 30+ varieties (530-686-9735; www.virtualseeds.com). The U. of Kentucky College of Agriculture offers an 80-pg booklet titled Tobacco in Kentucky. ATTRA's brochure, "Organic Tobacco Production," is at www.attra.org/attra-pub/tobacco.html. Start in pots as you would plants of the nightshade family (see Chapter 4). Transplant 1–2 feet apart to well-fertilized soil in full sun.

**NOTE:** Uncured tobacco can be much stronger than commercial cigarettes and dangerous to smoke. Curing lowers the nicotine content.

**Turmeric (Curcuma domestica, A.K.A. Curcuma longa):** This relative of ginger can be grown and harvested as you would ginger. It originated in tropical Asia and is now commercially grown in Haiti. Plant the root pieces 2 feet apart. Harvest the roots; wash them, sun-dry them for about 10 days, and then grind to a powder. The spice is used to make curry powders, as a food coloring and dye agent to make a golden shade, to season Far Eastern recipes, in wet mustard recipes for both its color and flavor, and as a saffron substitute. The dictionary says it's also used as a "stimulant." Available from Pacific Tree Farms.

**Vanilla:** Vanilla beans are the fruit of a Mexican climbing orchid (*Vanilla fragrans planifolia*). The orchid fruits naturally there, but anywhere else on the planet it has to be hand-pollinated. Vanilla begins fruiting at 3 years old, dies at about 10. If you don't live in a tropical climate, this is a greenhouse plant, wintering at no less than 60°F.

**Processing.** The skinny, 6-inch green pods and their beans don't have the sought-after flavor when picked. They have to be sweated and fermented for days while wrapped in a blanket. Next they are dried in the sun until thoroughly cured. The total time for fermenting plus sun-drying can be several months. They're done when vanillin, an aromatic substance, has developed in the beans; then they have that characteristic, wonderful flavor and fragrance and can be used in perfumes, potpourris, and cooking. By then they are dark brown in color.

**Using.** Cooking with the whole bean and pod results in remarkably better flavor than just using the extract. The seeds are edible. The pod adds to the flavor if tossed in too, but should be tossed back out after using and not eaten. That outer pod is good for flavoring baking custards and puddings. A 3-inch section of vanilla pod stirred into your mixture equals the flavoring of 1/2 t. vanilla extract. To cook with the pod, first split it; then scrape the beans into your food mixture. They can be boiled, or you can make your own extract. Use vanilla or its extract to flavor desserts of any sort.

**OLD-TIME VANILLA EXTRACT** Use 4 oz. vanilla beans, 16 oz. edible alcohol, and 16 oz. water. Slice the beans and cut into fine pieces with a sharp knife. Thoroughly powder them in a mortar with 1–2 oz. granulated sugar. Put the powder into the alcohol and water mixture. If you don't have pure alcohol and are substituting a strong whisky blend or brandy, use correspondingly less water. Let the vanilla soak in the liquid for 4 weeks. Strain. The liquid is your extract. Old-time imitation vanilla extract was sometimes made using half or all tonka beans in place of vanilla beans to make it cheaper.

**EASY VANILLA EXTRACT** Violet Stewart, Okay, OK, wrote me that she simply takes 1 qt. of any good 80-proof brandy, splits 2 vanilla beans, and drops them in. She cools it and lets it sit for 2 months before using.

**NONALCOHOLIC VANILLA EXTRACT** Mrs. G. Goodman, Randallstown, MD, wrote me, "Cut up vanilla bean into
small pieces, place in a bowl. Pour 1/4 c. boiling water over them; cover bowl, allow mixture to steep overnight. Blend mixture. Strain and return juice to the blender. Add 1/4 t. liquid lecithin, 1 T. honey, and 1 T. vegetable oil. Blend, pour into a bottle, cap, and refrigerate. Before using, shake well. Use same as commercial vanilla extract in recipes.

**Verbena, Lemon (Lippia citriodora):** This semi-hardy, perennial, fragrant bush has crinkly, pointed leaves and tiny mauve blossoms growing in spikes. It is sometimes confused with lemon balm, which is the one you want for culinary use. Lemon verbena has non-culinary uses such as perfume making and potpourri. (See also “Lemon Verbena.”)

**Violet:** There are several varieties of violet. Viola tricolor has edible flowers and leaves and is pretty in your garden or salad. Most violets are great in a potpourri because of their heavy perfume.

**Wintergreen (Gaultheria procumbens):** This is a very hardy (to ~30°F) little evergreen plant with small white flowers. It grows wild, ground-cover style, in coniferous forests of Minnesota, Wisconsin, New York, and Connecticut. Or you can order from Richter’s or Raintree Nursery. The berries are bright red and edible raw; nice in a fruit salad. Both leaves and fruit have that wintergreen flavor. Good ground cover.

**Planting.** It’s difficult to grow wintergreen in a domesticated setting. It will grow between 1,000 and 3,000 feet above sea level, but 2,000 feet is ideal. It is naturally adapted for a forest setting of open shade and acid soil. You’ll have better luck starting with nursery plants than with wild ones. Propagate by root division in the fall before frost or spring. Plant 12 inches apart in acid (its natural habitat is pine woods), well-drained, light soil. It’s a good idea to grow it in a lathe setting. It will grow between 1,000 and 3,000 feet above sea level, but 2,000 feet is ideal. It is naturally adapted for a forest setting of open shade and acid soil. You’ll have better luck starting with nursery plants than with wild ones. Propagate by root division in the fall before frost or spring. Plant 12 inches apart in acid (its natural habitat is pine woods), well-drained, light soil. It’s a good idea to grow it in a lathe shelter, since it must have full or partial shade to grow well. Or fake the woods to make it happy: Plant on a wooded hillside with a heavy pine needle mulch.

**Using.** Wintergreen or its extract is excellent in homemade root beer. Wintergreen flowers are edible and can be added to fruit salads or ice cream. Wintergreen leaves are nice to chew on fresh. Dried or fresh leaves make a fragrant tea. Harvest both berries and leaves in early September or October. Use 1 c. fresh leaves per 1 qt. water. The extract is used commercially to flavor gum and candy. The bright red berries are edible, sweet, and tasty. Neither berries nor leaves are dried. Make oil of wintergreen for out-of-season flavoring and fragrance uses.

**Witch Hazel (Hamamelis virginiana):** This slow-growing shrub (10–15 feet) native to eastern North America has yellow flowers that bloom in October and November. An alcohol extract of witch hazel bark is sold commercially as an astringent lotion. Available from Thompson & Morgan, Richter’s, etc.

**Woad (Isatis tinctora):** Do not eat. This European herb, also called dyer’s woad, is grown for the blue dye that can be extracted from its leaves. Seedpods are used in arrangements. It reseeds. “Woad” also refers to the dye itself. In 1861 a whimsical Orson Fowler wrote of “singing woad” which, when boiled, results in a “bird-pitched warbling and whistling that issue from the pot.” Available from Richter’s, etc.

**Wormseed:** See “Epazote.”

**Wormwood (Artemisia absinthum):** This hardy perennial grows 2–14 feet high. Propagate by root division or fall-planted seeds (viable for 2–3 years). Plant in poor, light soil, in partial shade. It gets several feet tall. Give it a spot by itself. Wormwood is strong stuff. It has a strong, disagreeable smell and can inhibit the growth of nearby plants, even herbs such as caraway, fennel, and sage. If you have harsh winters, cut it back and mulch heavily in the fall for protection.

Wormwood is usually harvested in fall. Dry the sprigs and use to make moth-repellent sachets. A strong wormwood tea can be used as a flea killer bath for your pets. It is used in flavoring absinthe and was traditionally used to treat worms (hence its name). A wormwood spray can protect against some pests. Available from Redwood City, Richter’s, etc.

**Yucca:** The roots of yucca contain saponin, a natural sudsing agent, good for washing delicate fabrics.

**Planting.** It takes 1–2 months to germinate at 65–75°F. Even after that, its growth tends to be slow and erratic. It needs easily draining soil. If in a pot, it actually does better if a little pot-bound. It’s not very hardy. Available from Richter’s, Thompson & Morgan, etc.

**Using.** Chop roots, soak in water, and stir to a lather.

### Cocoa, Coffee(s), and Tea

**Cocoa:** Cocoa trees (Theobroma cacao) originated in the tropical lowlands of Central America and southern Mexico. The tree seeds are cocoa beans. Foods made from them contain theobromine, a mild stimulant; caffeine, a stronger stimulant (in a much smaller amount than tea or coffee); and possibly also phenylethylamine, a mood lifter. So for medicinal purposes, chocolate can help the lethargic, the depressed, and the lovelorn. It can also make your toddler temporarily hyperactive. Hardy only to 32°F, cocoa trees are available from Pacific Tree Farms.

---

**Cocoa to Drink.** The original beverage made by ancient Native Americans by steeping the crushed bean in hot water was bitter but treasured. The Spanish tried adding sugar to sweeten it, and that helped. They also mixed ground cocoa beans with cinnamon and used them to create a wonderful meat sauce.

**Cocoa Butter.** In its natural state, the cocoa bean is about half fat, or cocoa butter. Because of all that fat, it is hard to dissolve cocoa. A Dutchman discovered a way to remove
half the fat; the resulting product, our familiar cocoa powder, is much more soluble and pleasant to drink. An enterprising Swiss entrepreneur discovered a way to use the cocoa butter removed in the process of making cocoa powder. He perfected a method by which machines rolled and kneaded the beans and at the same time doubled their fat content by adding the surplus cocoa butter from the powder-making process. The result was confectioner’s chocolate.

**Milk Chocolate.** Another Swiss man added milk and so created milk chocolate, a less concentrated and more pleasant product. Since then, chocolate has been selling by the ton.

**White Chocolate.** This is pure cocoa butter (all the rest of the bean removed) with sugar to sweeten it and vanilla to flavor it.

**Basic Cocoa Bean Processing.** Harvest the pods that hold the cocoa beans. Then split them open, shell out the beans, and let them ferment for a period. Then dry them and roast them. The familiar scent and taste of chocolate will not emerge until after the roasting. The beans actually consist of 2 layers, the outer shells and the inside “nibs,” which are the central “heart” of the bean. After the roasting, crack open those outer shells and discard them (they make great mulch). Grind the nibs enough to create some heat. The heat melts the cocoa butter portion of the nibs into a thick paste, referred to as the “chocolate liquor.” That liquor mixture is then poured into molds, square or bar-shaped, and cooled. After cooling, you now have unsweetened baking chocolate, the same stuff you can buy in the store!

**Making Cocoa Powder.** You have to get rid of half the fat and grind. To make fondant chocolate, add extra cocoa butter and knead it in. If you add sugar, vanilla, and powdered milk and knead them in, you’ll have milk chocolate. Results are affected by the varieties of cocoa beans you start with, the nature of the roasting stage, how much cocoa butter and sugar you add, and how long you knead it. More detailed recipes are manufacturer’s trade secrets that I couldn’t find out for you.

**HOT FUDGE SAUCE** Break 8 oz. unsweetened or semisweet baking chocolate into chunks. Combine chunks with 1 c. light cream in a heavy pan set on very low heat. Once the chocolate begins melting, stir constantly until the fudge is smooth and thick. If it’s too bitter for your taste, mix in sugar. Then take the pan off the heat source and stir in ½ t. vanilla. This is traditionally served over vanilla ice cream. Pour surplus sauce into a jar, cover, and refrigerate. It will keep at least several weeks. When you want to use it again, just reheat, again constantly stirring.

**BASIC MOCHA** “Mocha” means flavored with a mixture of chocolate and coffee. Combine 2 c. strong black coffee (instant is OK), 3 c. hot milk, 4 heaping T. chocolate powder, and 3 heaping T. sugar. (If chocolate powder is already sweetened, skip sugar.) Beat until foamy.

**SPICED MOCHA MIX** Combine 1 c. dry nondairy creamer, 1 c. cocoa powder, ½ c. instant coffee, ½ c. sugar, ½ t. cinnamon, and ¼ t. nutmeg. Keep it in a jar in a cool place. To serve, add 3–4 heaped t. to 1 c. very hot water. Nice served hot with a dollop of whipped cream on top, or cold with ice chunks in it, or with a big scoop of vanilla ice cream in it!

**COCOA INSECTICIDE** Soaking poultry with a strong tea made from cocoa leaves will clear them of lice. Cocoa shells are also lice-repellent and are useful mixed with animal bedding.

**COFFEE (GENUS COFFEA):** The coffee plant is native to east Africa. It looks like a small tree or shrub and grows up to 8 feet tall in a pot (up to 15 feet outdoors). A dwarf variety gets only 3 feet tall. Coffee can be grown in a temperate-zone garden if you transplant to a container and bring inside for the winter. The coffee plant is quite ornamental with its scented white flowers and shiny dark green foliage. The coffee plant can’t survive a frost and needs some shade to protect it from excessive sun. It can be grown outdoors in the California coastal area from about Santa Barbara on south. Pacific Tree Farms says their variety is hardy to 28°F.

Plants or seed are available from Richter’s, Pacific Tree Farms, Banana Tree, and Colin Westwood (who also offers growing instructions): 02-6677-6003; 196 Farrants Hill Rd., Conond, NSW, 2484 AUSTRALIA; coli7@bigpond.com.

**Planting.** Keep seeds dry before planting. Plant coffee seed on the soil surface in a sand-peat or half-organic mix. Keep warm (about 85°F) and allow a sizable time (a month or more) for germination. Once well started, transplant outdoors or to 4-inch pots. Grow potted coffee in well-drained soil; situate in a sunny window. Young coffee plants grow best at 70–75°F. If you have trouble with brown leaves, it means you’ve been watering too much, need to move the plant to a larger pot, or both.

**Harvesting.** For flowering and fruiting, the plants need 55–58°F night temperatures. Without those conditions, the plant will just grow bunches of lovely dark green glossy leaves—no flowers, no beans. Also be cautious with pruning. Cutting off the top does no harm, but trimming branches eliminates your crop, since flowers and beans grow there. The white flowers evolve into ½-inch fruits that are first green and then red, purple, or scarlet when ripe. When ripe, harvest them.

**Using.** Each pod contains 2 coffee beans, which you rescue from the outer pulp, dry, roast, grind, and soak in very hot water to make your beverage. (You can mail-order a coffee grinder from Lehman’s, 888-438-5346; www.Lehmans.com.) Coffee contains a lot of caffeine. An occasional cup can be a helpful sustainer in an emergency, but I know too many people who are addicted: They drink 30–40 cups a day, desperately wish they didn’t, and can’t stop. Heavy coffee consumption is definitely linked to pancreatic cancer.

**Coffee Grounds.** These, on the other hand, are a first-class, environmentally harmless deterrent to ants. To keep ants out of your house, or any other building, just lay a solid 3-inch layer against your foundation all the way around. To deal with an anthill, surround it likewise with a sizable ring of grounds. Grounds will also prevent cutworms (as do wood ashes). Just dig a shallow ditch around vulnerable plants and pour grounds into it. As they break down, they’ll also add fertility to the soil. Grounds are also great in your compost pile; earthworms love them and will quickly turn them into rich humus. And a manure/grounds/leafy mulch mixture added to poor soil will practically instantly make it fertile. No need to strain your pancreas! To get enough grounds to accomplish all this, just contact a business that brews coffee in quantity, and ask them to let you take all those unwanted coffee grounds off their hands!
COFFEES THAT AREN'T COFFEE: You can buy them at the store: Postum, Kaf-free Roma, etc. Mike and I have drunk Postum for years and enjoy it. It's made from ground and roasted grain. Mike drinks a heaping teaspoon of Postum in a cup of hot water. That's too strong for me. I like a level teaspoon with honey and milk, about one-third or one-fourth milk. I often make a whole coffee cup of it that way and share it with the children for breakfast. Unlike real coffee, "coffees that aren't coffee" can safely be shared with them. It's more comfortable than saying to children, "That's not good for you; you can't have any," while they stand there watching me drink it. The wise psychologists say our children imitate what we do and not what we say. In their innocent devotion, they try to follow the truest form of our behavior.

You can drink Postum in all milk, in milk with a dash of cocoa, made into an eggnog with milk, or with milk flavored with molasses. Another store-bought non-coffee product is called Yannoh. It is made from barley, wheat, soya, chickpeas, rice, dandelion, and burdock roots. You perk it just like coffee. If your grocer, co-op, or health-food store doesn't have it, ask them to order it for you.

ROASTED GRAIN COFFEE. Combine 8 c. wheat bran, 3 beaten eggs, 2 c. cornmeal, and 1 c. molasses or sorghum. Spread the mixture on a cookie sheet and bake slowly at about 200°F, stirring often. Boil with water to serve.

ACORN COFFEE. Select plump, round, sweet acorns. Shell and brown in oven. Grind in a coffee mill and use as ordinary coffee. Or hull ½ c. small sweet acorns. Add ½ c. cracked wheat. Mix. Roast in your oven. Pound in a mortar. Boil with water to get your coffee. Add honey, molasses, or brown sugar to sweeten.

DANDELION ROOT COFFEE. Dandelion coffee makes a surprisingly good substitute. Gather roots in the fall (October) or in the early spring before blooming. Scrub unpeeled roots with a stiff brush. Use the big part for a root vegetable (see "Dandelion" in Chapter 4). The skinny side roots are what you dry, grind, and roast. Dry them in the oven (150°F) until they are brittle and snap easily. Then roast them at about 375°F for 15–20 minutes or until they are dark brown inside. Grind in blender until they look like coffee, or use a rolling pin to grind to a coarse powder. Store in glass jars and use just as you would coffee. Boil about 1 t. per cup and stir it in. Your brew will have a flavor all its own, vaguely chocolaty and pleasing. You'll like it better every time the price of coffee goes up. But bear in mind that dandelion root is a powerful diuretic, so it may not be the best choice if you're pregnant.

Chicory Coffee. The mature roots of the Magdeburgh chicory variety (available from William Dam) can be dried, ground, and mixed with coffee to stretch it. Added to oven-browned barley, it makes a coffee substitute that has been very popular in Europe. (See "Chicory" in Chapter 4.) You can also make a chicory coffee from Wiltoof or wild chicory roots, but Magdeburgh is the specialist.

Unlike the other chicories, this is a perennial and needs a permanent corner of your garden. It has broad, smooth-edged, dark green leaves that grow in loose, upright (edible) heads. But what you're after is the 14–16-inch roots. Grow those roots an entire season long, at least 100 days. Or better yet, let them grow 2 summers. Then cut off the green tops (make salad). Scrub or scrape the roots, slice them, and string your little circles or strips of chicory on a thread. Hang up to dry. When completely dry, spread on a cookie sheet and roast at a low temperature until a very dark brown—they start to smell like chocolate cake. Taste to detect the moment of roasted perfection. Now cool the chicory. Grind it with mortar and pestle or some other means.

To brew chicory coffee, first boil a pot of water. Then drop in a spoonful of ground chicory, stir, let steep a few minutes, and there you are. Chicory is stronger than coffee, so use less. Serve plain or with honey and cream. You can make more chicory coffee out of the same grounds.

TEA: Tea leaves come from tea trees (Thea sinensis). They still grow wild in a few parts of the world, but they've been domesticated since ancient China. Tea handles pruning well and makes a fine hedge. It blooms in fall with small, fragrant, lovely white or pink flowers. The stimulant, caffeine, is a natural component of tea leaves. For more information, read Tea Growing by C.R. Harler (London: Oxford University Press, 1966), All About Tea by William H. Ukers (New York: The Tea & Coffee Trade Journal Co., 1935), or Tea for Home Use, a USDA pamphlet on how to cultivate and harvest home-grown tea, available from Redwood City.

Climate. Tea is a subtropical, evergreen plant of the camellia family that can't handle frost or snow and also dislikes high winds. If your climate has blistering sunshine, plant in partial shade. If you have a relatively cloudy, cool weather pattern, plant in full sun. Tea does best where there is warm, humid weather, temperatures don't drop below 24°F, and quite a bit of rainfall falls evenly distributed throughout the year. Morning fogs are wonderful for it. Tea will grow in southern California and the deep South. In colder areas, your tea trees can thrive and produce leaves in a container.

Varieties. There are about 30 different varieties. Unpruned wild teas grow 30–40 feet tall and belong to a large-leaf group. The domesticated teas are small-leaved, pruned to be shrubby, and allowed to grow only 4–15 feet high for easier harvesting. The tea tree has a round, dense nature. In the Far East you'd have many named varieties to choose from, but here you don't.

Planting. Tea plants are hard to find. Plant a half dozen to meet the tea-making needs of a family. You can mail-order seed from Park. Almost any soil, from sand to clay, will do, but tea needs acid soil with lots of organic material in it, a pH of 4–6, and good drainage (and no saltiness!). Plant tea seeds with their "eye" face down. Once you've grown a plant from seed, layering is another possible way of propagating, as is planting a cut branch or grafting. Water young plants regularly enough that their roots never dry out. Keep thick mulch over the roots. Be patient; tea plants grow very slowly. It will be years before your plant gets even 4 feet tall. Mature plants can get along with less regular watering.

Harvesting. In commercial tea plantations, the trees are fertilized, seeded, pruned, and harvested—all mechanically. (Pruning is done to cause new small leaves to grow as well as to shape the plant.) You'll be doing it by hand. Wait until your tea tree is at least 2–3 years old before you start. Then in early spring, when the weather gets warm and new leaves start to grow on the plant, pick just 2 or 3 leaves from the very tip of each branchlet. Those make the best tea. Harvesting doesn't hurt a tea plant's growth because you take only the new, outside leaves. Tea leaves can be harvested
from spring to fall—as long as you always choose the new leaves. Specialty teas may have special harvest times. Green tea and Pao Chung tea are harvested in spring and autumn. Certain black teas and oolong tea are harvested in the summer. "Green" and "black" teas refer not to tree varieties but to the result of different processing methods.

Making Green Tea. Place your just-plucked leaves in the top pan of your double boiler as is, covered but with no water over them. Fill the lower pan with water, bring it to boiling, and boil about 10 minutes. The leaves will now be much softer.

Pre-Drying: Spread them out thinly on a drying surface. Place your leaf-covered tray in an airy but shady spot. You want them to get limp, not brittle! After 12-24 hours (you'll learn the golden moment from experience), the leaves will be ready to roll.

Rolling: Lay out 1-2 cups of leaves on a clean rolling surface, roll firmly with a rolling pin, and then knead with your hands, just like bread dough. Spend about 10 minutes on this stage. Now evolve your kneading motion to incorporate a twisting, rolling movement that will gradually transform those leaves into a tight roll. By now some moisture should be coming out of them. If it isn't, you dried them too long, and you need to add about 1 T.t. water. Veteran tea-makers say that the tighter and longer the leaves are rolled (at least 30 minutes, please!), the more flavorful the tea.

Final Drying: After that, distribute leaves over a drying tray and dry in oven or dehydrator at a very low temperature and with good ventilation (oven door open). Toss and turn the leaves around once in a while to help the drying process. Continue drying at that gentle heat until they become totally dry (brittle).

Making Black Tea. Pick your leaves. Skip the heating process and go directly to the pre-drying and rolling. Then, before the final drying, add this curing step.

Curing: Press the leaves together into a dense ball shape. Wrap the ball tightly with plastic or a faintly moist cloth, and let rest in a somewhat cool room for about 8 hours. By now the leaves are distinctly fragrant and have changed to a copper color. Now do the final drying.

Storage. Have ready airtight containers for storage. Keep them in a cool place.

EAST INDIAN TEA Make black tea; add milk and honey. Keep heating. Add ginger, cinnamon, and ground cardamom to taste and serve.

HOMEMADE SPICED ORANGE TEA Crush 2½ t. whole cloves and five 2-inch cinnamon sticks to a chunky but not powdery stage. Combine with 1 lb. orange pekoe tea, 4 T. candied ginger (chopped fine), 4 T. dried orange peel, and 1 t. nutmeg. Just 1 t. of this tea makes 1 cup for serving. Steep about 10 minutes before drinking. For company, serve with an orange slice and sweetener.

The oldest sections of my book were written before my readers got the message through to me that I was supposed to sound like myself instead of a book. I figured that out later. With the first 2 issues of the book that I mailed out to "subscribers," I also sent cover letters to explain a few things (make my excuses). So many people wrote back to say my book would do, but what they really enjoyed was the cover letters! After that, I tried to do all my writing the same way as those cover letters. I've been leafing through those old letters. Here's part of one I wrote in February 1971:

"Thank you very much for your check and order for the Old Fashioned Recipe Book! I will send it as soon as possible, but I must beg your patience because that may be as long as a month yet."

No kidding, I said that. At that time I had no understanding of the real size and nature of the job I'd gotten myself hooked into. It wasn't until 3 years later, in 1974, that I actually finished that first edition.

Do-It-Yourself Cosmetics

Here's another whole category of environmental poisons that we could do away with. In Japanese the words for "pretty" and "healthy" are the same. Once when I was bemoaning my adolescent imperfections, my mother said, "To be young is to be beautiful." At the time I thought she was talking nonsense. Now I'm the age she was then and I understand the truth of it. The lily doesn't need to be gilded. My father taught that beauty was on the inside, that it consisted of glowing good health and a fine character. On the other hand, maybe I lean too far toward being unconscious of appearances. I could have won the worst-dressed prize every year of my life. And somebody else had to tell me to put natural cosmetics in this book.

I'm glad she did, for once I got started looking for these formulas, they turned out to be great fun to try! Experiment and see which ingredients suit you best. But don't forget that your skin's condition is influenced most of all by your diet, age, amount of exercise, and amount of sleep. Too much stress in your life, too little humidity in your air, too much exposure to sun, and too much fatty, sweety, junky, chemicalized food can be doing your appearance far more harm than these treatments by themselves can relieve.

NOTE: To prevent allergic reactions, test a small quantity of any unaccustomed substance by rubbing it on the underside of your arm. Then wait 24-48 hours to see if a rash develops.

FOR YOUR FACE

Analyze Your Skin Type. What you put on your skin should be appropriate for its type. Only very oily skin should be dosed with highly acid treatments like citrus fruits (lemon, lime, grapefruit), Concord grapes, strawberries, or apples. If you don't have very oily skin but want an acid skin treatment, use fruits that are a little less acid than the previous list—peaches, apricots, grapes other than Concord, and tomatoes. If you want a beneficial fruit treatment whose acidity is about the same as that of normal
POISONOUS PLANTS

Here are some poisonous plants to look out for. This list was sent to me by my dear friend Violet Stewart. She wrote me, “I hope you can find a space for this in your book. I’ll feel I may have had a part in saving one life.” I did find space—and since then I’ve learned and added more.

**Aconite:** All parts.

**American False Hellebore**

Anemone (wind flower): Nemerosa is poisonous.

Angel's Trumpet (Datura): All parts poisonous.

**Arrowgrass**

Azalea: All parts very dangerous—nausea and vomiting, depression, hard to breathe, prostration, fatal coma.

**Baneberry:** Berries, red or white, are poisonous.

**Black Locust:** Flower is edible; rest is poisonous.

**Bleeding Heart:** Leaves and roots may be poisonous in large amounts.

**Bloodroot**

**Bouncing Bet**

Butterflyweed

Castor Oil Plant (Ricinus communis): One or two castor bean seeds are a near fatal dose to an adult, let alone a child.

**Celadine Poppy**

**Chokecherry:** Leaves and seeds are poisonous.

**Christmas Rose (Helleborus):** Seeds and all plant parts are poisonous.

Cockle, Corn or Purple: All parts are poisonous.

Columbine (Aquilegia): Seed/all plant parts poisonous.

Crocus: Autumn crocus bulbs can be dangerous.

**Daffodil:** Bulb causes nausea, vomiting, diarrhea, and may be fatal. Sap makes your hand swell up if it gets into a cut.

Daphne: A few of the berries can kill a child.

Datura: See “Angel's Trumpet.”

**Daylily:** Roots are poisonous.

Deadly Nightshade

**Death Camas**

**Desert Rose (Adenium):** The milky juice may be a heart poison.

**Dieffenbachia:** All plant parts cause intense burning and irritation of mouth and tongue. If the tongue swells and closes the throat, no air can get through.

Digitalis: See “Foxglove.”

**Dutchman's Pipe (Aristolochia):** All plant parts are poisonous.

**English Ivy**

**European Bittersweet**

**Foxglove (Digitalis):** All plant parts poisonous. Leaves contain digitalis, a heart stimulant. In large amounts it can be fatal.

**Frangipani (Plamaria):** Poisonous sap.

**Garland Flower:** Poisonous berries.

**Hemlock:** Read the story at the end of this chapter.

**Horse Chestnut, Horse Nettle, and Horsetail**

**Hyacinth:** Eating the bulb will cause nausea, vomiting, diarrhea, and may be fatal.

**Iris:** Entire plant is poisonous.

**Jack in the Pulpit**

**Jessamine:** Berries are fatal.

**Jimson Weed**

**Larkspur (annual delphinium):** Poisonous seeds and leaves.

**Larsonia:** The seeds can be fatal.

Laurel: All plant parts can be fatal, producing nausea and vomiting, difficulty in breathing, prostration, and coma.

**Leafy Spurge**

**Lily, Flame:** All plant parts are poisonous.

**Lily, Glory:** The tubers are highly poisonous.

**Lily of the Valley:** The leaves and flowers disrupt heartbeat, stomach, and mind.

**Lobelia:** Poisonous.

**Lupine:** All plant parts, including seeds, poisonous.

**Marsh Marigold**

**Marvel of Peru (Mirabilis):** All plant parts poisonous.

**Matrimony Vine**

**Mayapple:** Poisonous; fruit is also poisonous if too much is eaten and must be yellow, totally ripe, and smell sweet.

**Meadow Saffron**

Mistletoe: Berries can be fatal to children or adults.

**Monkshood (Aconitum):** All parts, including roots, are poisonous.

**Morning Glory (Ipomoea): All plant parts poisonous.**

**Mountain Laurel**

Narcissus: Bulbs are poisonous—cause nausea, vomiting, diarrhea, and may be fatal. Oleander: Leaves and branches are poisonous—affect heart, cause severe digestive upset, have killed.

Pennyroyal: Poisonous.

Poinsettia: Even one leaf can kill a child.

Poison Ivy

**Poison Oak**

**Pokeweed:** Young shoots up to 6 in., if free of purple coloring, are edible if boiled in a sequence of two discarded waters. Rest is poisonous.

Poppies, Horned (Glaucium): Roots are poisonous.

**Poppy, Iceland:** All plant parts are poisonous.

**Poppy, Somniferum:** Fruits and sap are poisonous.

Privet

**Rhododendron:** All parts can be fatal—nausea and vomiting, difficulty in breathing, prostration, coma.

**Rhubarb:** The leaves, even cooked, can cause convulsions and coma, soon followed by death.

**Rosary Pea:** A single seed has caused death.

**St. Johnswort**

**Skunk Cabbage**

Snowdrops

**Solomon's Seal (Polygonatum):** The seeds and all plant parts are poisonous.

**Star of Bethlehem**

**Tobacco (Nicotiana):** All species/plant parts poison.

**Wisteria:** Poisonous.

**Yew:** Berries and leaves (more so) are fatal. Death is sudden—no warning symptoms.

[Note: The text provided is a list of poisonous plants with symptoms and common names.]
deep-cleans your facial pores. To experts, steaming means putting your face in a hot towel tent. To me, it means spending 5–10 minutes with a few hot washrags on my face. When you’re done, wash out any dirt that’s left; then close those pores with cold washrags or an astringent.

**NOTE:** Do not use this or any other heat treatment on a face that already has broken veins, because it can make them worse.

### Face Masks

A mask consists of a “binder” (which makes it adhere) and other ingredients mixed in with the binder. Choose your binder according to whether your skin tends to be oily or dry. For oily skin, use yogurt or egg white as a binder. For dry skin, choose lanolin, honey, sour cream, or egg yolk. Experiment with the other ingredients. You can blend vegetables and fruits and combine them with your binder, or use any of the recipes below. Wash your face clean before applying the mask. Don’t ever put a mask onto the area around your eyes. Rinse off after a half hour or as soon as the mask dries. (While you’re waiting, it’s a good time to take a nap.) To remove the mask, use a washrag and warm water. Then use cold water to close your pores.

**NOTE:** If you feel any irritation, rinse off immediately!

#### EGG WHITE MASK

This helps drag blackheads and whiteheads out of your pores. Slightly beat an egg white and spread it fairly thickly over your face. Let it dry. Do the same thing with another egg white right on top of the first.

#### OATMEAL MASK

Mix together ½ c. oatmeal and enough honey to make a pasty consistency. Optionally, add 2 t. rose water.

#### HONEY/LEMON MASK

Mix 2 T. slightly warmed honey with 1 t. lemon juice. Put the mixture on your face and leave for about a half hour.

#### BREWER’S YEAST MASK

Mix yeast with enough water to create a paste. Smooth it over your face (not into eyes!). Let dry. Then remove with warm water. Do this 1–2 times a week. For dry skin, add 1 T. wheat germ oil or 1 egg yolk to mask. You can also add 3 t. brewer’s yeast to milk or fruit juice and drink it daily.

### Skin Cleansers

#### INSTANT SKIN CLEANSER

Get a lather up with mild soap. Sprinkle some kitchen commeal into the lather and rub and scrub your face with the mixture. See “Elderberry” in Chapter 6 for more recipes.

#### YOGURT CLEANSER

Mix yogurt with a tiny dash of salt. Not for dry skin.

#### CLEANSING CREAM

In a double boiler, melt and mix together ½ c. safflower (or sweet almond) oil, 1 T. cocoa butter, and 1 T. anhydrous lanolin. Take off the heat, beat until partly cooled, and store in a jar. Shake before using.

#### FRUIT CLEANSER

Sliced tomato or cucumber.

#### HERBAL STEAMING FACIAL

Moisten your hot washrags with an herb tea—chamomile, nettle, rosemary, or peppermint.

### Other Treatments

#### ASTRINGENTS

Use peeled cucumbers, lemon juice and water, or rose water.

#### SKIN FRESHENER

Try a strong mint-tea facial.

#### PEACHES AND CREAM MOISTURIZER

Blend together 1 ripe peach and heavy cream. Refrigerate. Massage onto your skin wherever needed once per day.

#### TREATMENT FOR LARGE PORES

Put 4 T. bran mixed with the chopped skins of 2 lemons into a jelly bag. Dip it into boiling water. Apply to face with enough pressure on bag contents to squeeze out a little of the lemon quality. Repeat for a while.

#### FOR OILY SKIN

Try cold parsley tea dabbed on several times a day.

#### HOMEMADE LIP GLOSS OR ROUGE

Mix a drop of food coloring with a fingerful of petroleum jelly. Kids have fun with this, and it won’t hurt their skin.

### FOR YOUR BODY

For a recipe for herbal hand lotion, see “Products and Processes.”

#### Herbal Bath

Make a strong tea by pouring boiling water over your chosen herbs. Let steep while you draw your bathwater. Then strain into the water. Or just put herbs right in your bath water—either loose or in a little cheesecloth bag. Let them steep 10 minutes; then join them in there. Good herbs for bathing are chamomile, lemon verbena, mint, peppermint, and rosemary.

#### HERBAL BATH SALTS

With Epsom salts, mix sage, thyme, and pennyroyal; lemon balm and peppermint; lavender, rosemary, and pennyroyal; or another herb or herbal combination that pleases you. Or use Epsom salts with a few drops of your favorite fragrance or herbal oil mixed in. When bottled attractively, this makes a nice gift.

#### FOR YOUR HAIR

**HEALTHIER HAIR**

Take vitamin A and D supplements daily, plus 1 t. brewer’s yeast.

#### VINEGAR HAIR RINSE

Mix 3 T. vinegar per ½ gal. water.

#### HERBAL HAIR RINSE

Rinse your hair in herb tea. Chamomile is best for blondes, rosemary for brunettes.

#### BALSAM HAIR RINSE

Pour 1 qt. balsam fir needles with a hammer to release the oils. Then soak them in cold water overnight. Rub in 2 T. of your balsam rinse after shampooing and rinsing. Rinse well again.

#### CHAMOMILE SHAMPOO

Barb Ingram, Santa, ID, says she uses this formula: Put 1 T. soap flakes, 1 T. borax, and 1 oz. powdered chamomile flowers into a basin. Add ½ pint hot water. Heat until thick lather is formed. Wet hair with warm water, massage, rinse, and wash again. (For a general herbal shampoo recipe, see “Products and Processes.”)

#### FOR YOUR TEETH

**HOMEMADE TOOTHPASTE**

You can use common table salt for a toothpaste. It’s rougher on your teeth and mouth and doesn’t taste as good, but it’s cheap and available. Takes care of bad breath too! Or use plain baking soda; baking soda with a drop of oil of spearmint, peppermint, cinnamon, or cloves in it; a mixture of 3 parts baking soda and 1 part salt; or, best of all, a mixture of 4 t. baking soda, 1 t. salt, 1 t. mint flavoring; and just enough water to get a toothpasty texture (about ½–1 t). Keep any moist
Hemlock is a biennial and a member of the carrot family. The first year it grows low and has a very carrot-like top; its energy goes into making a sturdy root, which is its most poisonous part. The next year, energy from that big root pours up into building a sturdy, tall stalk, 5-6 feet high—perfect-looking whistle material. Then it flowers and makes seed at the top of the stalk.

Its flowers and seeds are poisonous too. Some neighbors down the road with a lot of the stuff chopped it all down, gathered it into a pile, and set fire to it. The smoke made their whole family sick. The county weed control agent, Homer Fudder, told them that fumes from burning hemlock were also poisonous. Homer has a personal campaign to try to stop the hemlock and to stop people from dying of it. He told me you can even die if you try to pull out the plant and have a cut on your hand that hemlock juice gets into.

But you say you've got a book that tells you which wild foods are edible and which aren't. Well, right in front of me I have an article called "Principal Food Plants of the United States," published in an utterly respectable wilderness and country living magazine. It says, "HEMLOCK—(all year) young tips used for tea and formerly in root beer; inner bark used for breadstuff, sap, potable." It doesn't distinguish between the nonpoisonous hemlock tree and the poisonous hemlock plant. If that one entry in a list of a couple hundred "food plants" is so potentially misleading, how much can others be trusted? What about the books that describe plants that have "medicinal uses"? I found hemlock in one of those, too. It said it was "good to strengthen male potency."

Take it from a professional author: Don't believe everything you read. So often authors end up simply collecting information already in print—with the ever-present danger of passing on somebody else's error. Or they have to put the ideas in their own words so it isn't plagiarizing, and they end up restating something in such a way that the facts become distorted. Or they write down hearsay that simply isn't true. That's scary when the results could be fatal. That's why this book doesn't have a real wild-foods section. You'll find wild foods mentioned here and there within it: nettle tea, poke salet from the South, dandelion root and greens, elderberries and chokecherries—but only when I know from personal experience or from common experience of friends and neighbors that at least part of the plant really is edible, and when it's commonly known and easily identified.

I don't mean to put down the bulk of the wonderful research that has been done on wild foods, but be cautious what you put in your sandwich. A good program on wild foods comes from Miriam Kramer at Wilderness Leadership International: 909-796-8501; 24414 University Ave. #34, Loma Linda, CA 92354; outdoorsurvival@yahoo.com; www.outdooreduquip.com. They sell correspondence courses in edible wild plants, using herbs, and wilderness survival. "Dining on the Wilds" is a 6-hr. video set with two manuals.

The Wild Foods Forum is published by Vicki Shufer, Virginia Beach, VA; 757-421-3929; wildfood@infi.net. Goosefoot Acres: Center for Resourceful Living publishes a Directory of Edible Wild Plant Educators, sells books, sponsors contests, and publishes a newsletter on using wild foods: 216-932-2145; orders 800-697-4858; PO Box 18016, Cleveland, OH 44118; petergail@aol.com; www.edibleweeds.com. Peter is a Ph.D. ethnobotanist, author of eight books, 250 articles, and inspiration of the National Dandelion Cook-off (first weekend in May; Dover, OH)! For $35/yr, join Defenders of Dandelions, and get Peter's book, Dandelion Celebration: A Guide to Unexpected Cuisine, plus T-shirt or tote bag and newsletter, Dandelion Doings.

Could a rancher who had lived in the country all his life make a mistake in his plant identification? Just a month ago, I happened to be standing close by when three innocent visitors to the School of Country Living (Julaine Konselman, a young widow; her 12-year-old only son; and Jack Clark, a local businessman) ate hemlock after a local pointed out a plant he called "Indian celery" and urged, "Try it." (The showing-off-his-"knowledge" local didn't himself partake.)
I wish I'd managed to stop them before they swallowed the stuff. But I did break up their idyllic stroll through a pasture immediately after they ate it, rushed them to town, ran to the drugstore, bought Ipecac (the stuff that makes you throw up), and made them drink it. Jack and Julaine's son threw up, but she didn't. "I'm sorry," she apologized. "I never throw up." Then I recruited friends to rush them the 28 miles to the emergency room of the Lewiston hospital, where all three got their stomachs pumped. After a night's sleep, they all felt okay—good enough, in fact, that Jack kept wondering if I'd put him through all that misery for nothing. The Ipecac and the stomach pump—indeed, that Jack kept wondering if I'd put him through all that misery for nothing. "I never throw up." Then I recruited friends to rush them the 28 miles to the emergency room of the Lewiston hospital, where all three got their stomachs pumped. After a night's sleep, they all felt okay—good enough, in fact, that Jack kept wondering if I'd put him through all that misery for nothing. The Ipecac and the stomach pumping was enough to make a person feel lousy, he figured. And the rancher kept insisting it really was just "Indian celery.” So a week later, Jack returned to that pasture, picked a specimen of the exact same stuff he and the others had eaten, and took it to the office of a poison weed specialist at the University of Idaho. When he walked into the professor’s office, it was noontime and the gentleman was reading at his desk. Jack set the plant down in front of him and said, “I ate some of that.” The scholar looked up from his book at Jack, and at the plant. His eyes widened. He half-rose from his chair. “How long ago?” he nervously asked. “A week ago,” Jack coolly replied. There was a long silence. “You ought to be dead,” the professor finally muttered. “You’re very lucky.” “What is this plant?” Jack asked. “Hemlock . . . deadly poisonous.”

OF GREEN LEAVES, AND COURAGE, AND FOOLISHNESS ..........488
The bulk of what follows used to make up the "Sweets" chapter, and there was a lot more in it about how to make apple butter than about how to grow a tree. Now, as I sit down to write this new edition, I am more worried about preserving the topsoil, maintaining our atmospheric oxygen, and reducing the earth's carbon dioxide level (and risk of a disastrous "greenhouse effect") than I am in making sure you can cook apple butter. Apple butter is still here, but I've added as much as I could (not as much as I wanted) about trees. Trees are the single most important answer to those 3 most critical challenges for the future of life on earth.

The massive, semipermanent root networks of trees forestall erosion and make possible a form of long-term agriculture that can sustain humans and their livestock without the loss of topsoil and the desertification of their agricultural land, which is the great risk of annual tillage for generations. The leaves of trees both yield oxygen and remove carbon dioxide as part of their natural chemistry. And, as if that isn't good enough, you can plant entire forests, or plantations, or farm crops of trees that also provide food. Fruit, yes, of course. But not just fruit. Tree fruits are wonderful: apples, pears, peaches, and nectarines from the temperate zones, and avocado, banana, persimmon, guava, and a long list of others that grow in warmer climates. In Central Asia there are forests made up entirely of various kinds of fruiting trees, all growing wild—gardens of Eden. In the United States before 1900 there were vast wild nut forests, mainly chestnuts, which made up a third or even a half of the total tree population, and under which the pioneers' pig herds roamed untended—reproducing and flourishing until their surplus was needed for table meat. But the magnificent, towering hardwood forests of walnut and such have long since been cut down to make dressers and coffee tables. The Eastern chestnuts all died in the terrible epidemic of a new disease (some Western ones survived)—chestnut blight—that struck the forests in the early 1900s.

There are trees that build up the soil—nitrogen fixers, exactly like beans, peas, and alfalfa in your garden and field. Mesquite is one, for example, whose leaves and fruits are edible and relished by meat, milk, and egg producers are called "livestock fodder trees." These trees are important because such an agriculture is virtually permanent and totally nondestructive. The trees and the pasture beneath them stay put so there is no soil erosion from tilling multiple times each year, no bare fields of dirt to blow or wash away. And the dense tree foliage and pasture beneath maximize the contribution green stuff makes to good air, as well as to meat supply. The Mediterranean farmers have a garden space, too, but it doesn't have to be very big. There are farmers in the United States who also do some variety of 2-story farming. They can turn swampy, marginal land into an almost effortless wealth producer by planting a forest of stock-feed dropping trees—not just accidentally this kind or that, but a carefully planned layout to provide as nearly as possible a year-round fall of fodder for the animals: one tree crop raining down its bounty early in spring, another that fruits in mid-summer, still another in fall, and another for late fall feeding. And the animals in turn nourish the trees by their manure. That's how it has to be for this ecosystem to be permanently healthy. The cycle has to be complete: plants give what animals need; animals return what plants need.

Of course, I have added as much as I could about trees.
PLANTING A TREE

Someone asked Martin Luther, “What should I do on the last day of earth?” Luther replied, “Plant a tree.”

It’s a wonderful, spiritual thing to plant a tree. Each tree is a living thing that can share the rest of your life. It will grow and give you shade, elegant beauty, food to eat, and branches for birds to nest in and children to climb in and for you to hang your hammock on and take a well-deserved nap. No matter what, plant one or more trees every year. And plant as many—or more—as what you take out. If you’re planting various kinds of trees your harvesting will be staggered because they grow at different rates and you may be harvesting different sorts of products from them. You can sell Christmas trees, nuts, maple syrup, firewood, fence posts, sawlogs, and fruit. If you have livestock fodder and peahens, which protect his trees from insects and also provide a cash crop from feathers that Bill collects during their molting seasons, plus sale of live birds. He also raises bees, which feed themselves from the tree blossoms, perform pollination duties, and make prime honey.

So we need to keep the trees we have. And we need to plant more. In England farmers love their pastures, and I’ve heard they fence them not with posts hacked from the bodies of dead trees but with ingeniously devised barriers made of closely growing and intertwined living trees called “hedgerows.” Their hedgerows, made of ash, elm, heather, holly, ivy, and willow, provide some winter food for livestock, summer and winter harvests for people and animals, shelter for some wild critters, privacy, and a guaranteed role on their land for trees. For how to create one, refer to Hedgerow by Eric Thomas and John T. White (New York: Morrow, 1980).

We need to shut down or convert the high-sulfur coal-based industries and replant the forests that have been poisoned. We need to replant as much as possible of all the earth’s lands that were once forested. In areas where natural rainfall supports forests, we need to make a conscious agricultural evolution from an open-field-based agriculture to a tree-based or 2-storied agriculture. That's the next great agricultural revolution.

I have an insistent vision of a wonderful earth thousands of years from now, with healthy air and water and healthy, happy, cultured, literate humans living on it. They survive and thrive in carefully maintained balance and companionship with and humble service to the plants and animals that sustain them. In those places where trees can naturally grow, I see people living contentedly under a canopy of green leaves.

I like the idea of planting trees for grandchildren—or for generations to come. As each year goes by, other people’s children look more like my children to me. The older I get the more it feels like I’m related to everyone I meet and that the children and their children to come are all somehow my offspring, too. I’m understanding last in a fully integrated way that all humans are ultimately family, and beyond them, we are connected to all animals, too, and beyond them, with all life. Yes, related to a tree. And not so distantly as we might think. Trees and people are far more closely related to each other than either is to a rock!

Choosing trees to plant can be very exciting. How about a Dawn Redwood, one of the ancient species that dates back to the Upper Cretaceous era, 100 million years ago? How about the honey locust, a wonderful drought-resistant cold-hardy tree that will grow hundreds of pounds of pig and cattle fodder each year for winter feeding and also, being a legume, enriches the soil? Plant a tree for your anniversary, or your birthday, or Arbor Day, or . . . It's actually good to mix your species. Get the right combination and you have an ideal permaculture.

NOTE: For easier reference, most recipes in this chapter are grouped together with a particular nut or fruit. However, preparation details are not repeated each time if they are covered in Chapter 7. If your recipe seems incomplete or vague, refer to that chapter to find the rest of the processing information.

trees (which are perhaps 40 feet apart), these 2-story farmers raise annual crops of grain or vegetables. Because of the partial shade of the trees, their tilled crop doesn't yield as much as it would in full sun. But the Mediterranean communities of which I spoke have been doing this for centuries, and the depth of their topsoil and its fertility is undiminished, whereas in far too many neighboring countries there is bare rock or desert now where centuries ago fertile farms provided the basis of ancient civilizations. The success of their 2-story farming is due to the trees, which hold soil in place and perpetually enrich it with their annual generosity of falling leaves and fruits. (Did you ever hear of terrible famines like those of Ethiopia and Somalia happening to people who live in the middle of a dense forest? I haven't.)

Another form of 2-story farming is described in the Tilth organization's visionary classic The Future Is Abundant ("Chopaka Nut Orchard," by Michael Pilarski, p. 106): a nut orchard with 2 heights of trees. "The upper story of the nut orchard consists of walnuts, Chinese chestnuts, heartnuts and a few Turkish hazels (Corylus colurnd). The middle story is composed mainly of filberts, with some pears, peaches, and plums. The south side of the orchard is planted to peaches and nectarines to take advantage of the warm, sunny exposure. On the west side grapes have been trained along the high deer fence which surrounds the orchard. . . Bill [the grower] has found that spacing the walnut trees 60 feet apart and the filbert trees 25 feet apart is ideal." On the ground story of his orchard, Bill raises yet another crop, peacocks and peahens, which protect his trees from insects and also provide a cash crop from feathers that Bill collects during their molting seasons, plus sale of live birds. He also raises bees, which feed themselves from the tree blossoms, perform pollination duties, and make prime honey.

So we need to keep the trees we have. And we need to plant more. In England farmers love their pastures, and I've heard they fence them not with posts hacked from the bodies of dead trees but with ingeniously devised barriers made of closely growing and intertwined living trees called "hedgerows." Their hedgerows, made of ash, elm, heather, holly, ivy, and willow, provide some winter food for livestock, summer and winter harvests for people and animals, shelter for some wild critters, privacy, and a guaranteed role on their land for trees. For how to create one, refer to Hedgerow by Eric Thomas and John T. White (New York: Morrow, 1980).

We need to shut down or convert the high-sulfur coal-based industries and replant the forests that have been poisoned. We need to replant as much as possible of all the earth's lands that were once forested. In areas where natural rainfall supports forests, we need to make a conscious agricultural evolution from an open-field-based agriculture to a tree-based or 2-storied agriculture. That's the next great agricultural revolution.

I have an insistent vision of a wonderful earth thousands of years from now, with healthy air and water and healthy, happy, cultured, literate humans living on it. A TREE QUIZ

Hint: All answers are shrubs or trees that bear an edible crop.

1. If you can grow oranges on your irrigated fertile bottom land, what tree will thrive on your steep, rocky, poor-soil, and hillsides?
2. What temperate-zone fruit has an 8- to 12-inch deciduous leaf, bears a delicious 5-inch fruit, is hardy to -30°F, can grow in partial shade, can handle the competition of being in the middle of a lawn, and is virtually pest- and disease-free?
3. What tree takes 40 years to reach full maturity but then will produce a generous human-food and stock-food crop annually— even through drought and total neglect—for centuries?
4. What tree, hardy to 20°F or able to live in a container and winter in a basement, will bear 2 crops of fruit, one in June and the other in August, and (out of the South) is usually not bothered by pests or diseases?
5. What temperate to subtropical zone fruit will grow in subsoil clay where all the topsoil has washed away, or in sand; is drought-resistant once established; can grow in a lawn; can provide ripe fruit continuously from August or September to December or February; will store fruit in good condition on the tree all that time (or the fruit will keep on the ground for another month or two, even after freezes); bears fruit generously; and yields prized carving wood?
6. What plant that is not a pear, but is related to the pear, is a good choice if you have poorly drained soil. This plant can produce yellow, baseball-sized fruits in zones 5–9 despite late frosts, or drought.

7. What temperate-zone fruit tree can grow almost anywhere, can handle the competition of a lawn, heavy or poor soil and poor drainage, could get along on one deep watering a month, needs little pruning, is immune to fire blight, can produce for up to 75 years, and bears fruit you can store in your cellar 2–3 months while you get around to eating or preserving them?

Answers to quiz: 1. Carob. 2. Pawpaw. 3. Carob. 4. Fig. 5. American persimmon. 6. Quince. 7. Keiffer pear.

Guerrilla Tree Planting

I'm for it, urban, or rural: guerrilla tree planting. Choose the right species for the climate and suitable sites: a neglected space on private land, or an open one on public land. Then you sneak up and plant your tree there. Trees can handle a lot of crowding; 15 feet apart is fine in a forest setting. During the planting seasons of spring and fall, plant trees on your weekend outings. Plant trees on your holidays. Don't leave town without some seeds or seedlings in your back seat. Don't go picnicking or backpacking without a few gifts to the earth in the form of seeds or seedlings: evergreens, or fruit or nut trees. You can start them in a nursery bed in your yard, or in a flat or pot in your window. Plant in the morning sun or by the full moon. Keep a private tally: how many trees you've planted so far. Take pride in it. Go back and visit some of them years later and say, "Hi, I'm your parent. My, but you're looking good!" Expect some losses; it's okay.

If people are the whole problem, people can just as easily be the whole answer. All they gotta do is do it. A guerrilla tree-planting friend, ex-Viet Nam vet, proposed with a crooked grin and a twinkle in his eye, "Let's cluster-bomb the planet with trees!"

Amen.

It takes a long time for a tree to grow, and some of them may not make it. And, sooner or later, grown trees, like people, die of old age. But then they can be fuel or building material, or a home for wild things until they finally decay and become food for other trees in the fullest completion of their life cycle. In the space where they once lived, plant new trees, continuing their spirit of hope. Plant a tree for your housewarming, and one for each anniversary, one for farewell—any excuse will do, the more often the better!
Hopefully you’ll end up with a big, diversified nut and fruit orchard, and vine and berry plants, too. You’ll probably be surprised at the amount of fruit and nuts your family could use if they had all they wanted. I canned 100 qts. of cherries last summer, and here it is the first day of February and I have only 1 qt. left. But I still have apricots, plums, grape and tomato juice, apple plum butter, and a lone jar of applesauce, so we aren’t clear to the end. The cherries are my family’s favorite fruit, and I haven’t been too strict on the rationing. As the year wears on and the favorite fruits like cherries, peaches, and pears are eaten up, the others start looking better and tasting better to them. Your local extension agent or nursery can advise you what varieties do best in your climate, when they ripen, what pollinators they need, etc.

Climate

Is your climate subtropical or tropical, or temperate? What fruits you grow depends mainly on climate unless you’re doing greenhouse farming. The farther north you live, the higher in altitude you are, the shorter your frost-free season. In colder areas you may be limited to apples and cherries, and colder than that to crab apples. Colder yet, and chokecherries or sand or bush cherries, gooseberries, and maybe a few other berries are your only possible fruit crops. The farther south you live, the more fruits you can add to the list. But temperate-zone fruits won’t do well where bananas grow. Deciduous trees need a cold winter for their normal annual cycle. Each temperate-zone species usually needs a specific number of hours spent below a certain temperature in order to break its dormancy and make it resume growing and bearing fruit normally again in the spring: its “chilling requirement.”

If you live in a hot zone, here’s a letter from Ella Hupman, Fort Lauderdale, FL, that’s bound to set you dreaming. “Dear Carla, We decided that it was just as easy to raise vegetables as flowers and grass, and fruit trees instead of shade trees. We took out all our areca palms and planted about 10 varieties of bananas. Also put in orange, grapefruit, tangerine, avocado, mango, Key lime, lemon, calamondin, and carambola trees. After 3 years of gardening, we know what vegetables we can produce with greatest success. Our tomatoes have been most successful and I’ve canned them in every form. Rabbits are our source of fertilizer besides a source of meat.”

She didn’t plant any apple, cherry, apricot, plum, peach, nectarine, or pear trees. Those are temperate-climate fruits. So you can be blessed with fruit wherever you live—but not necessarily the same fruit. However, there are some tropical fruits you can grow in a tub and bring in when it’s too cold for them outside: banana, pygmy date palm, everbearing fig, pineapple, pomegranate, and dwarf citrus.

Choosing Your Plants

You need expert advice about what combinations to buy. POLLINATORS: Some nut and fruit trees, and vines (such as kiwi), can’t make fruit alone; they can be either male or female, and they need another tree to be a pollinator for them. Other trees are “self-fruitful” or “self-fertile” or “self-pollinating.” There are trees that are kind of in-between; they’ll produce some harvest, but only a small crop unless they get cross-pollinated by a different plant. Trees that are to be wind-pollinated should be planted within 100 feet of each other.

LATE FROSTS: If there happens to be a freeze while fruit or nut flowers are blooming, there will be no crop of fruit. Having as large and diversified a fruit patch as possible guarantees that, although frost will probably catch some of your trees in bloom (and pests and diseases may take a toll on others), lots more will still make it through, because different kinds of fruit and different varieties of the same fruit have different blossoming dates—earlier and later. Furthermore, if late frosts are a problem in your area, you can avoid trouble by seeking out varieties that bloom late enough to be fairly safe.

SIZE: Dwarf, Semi-dwarf, and Standard: One of the main questions you have to ask when shopping for a tree is, “How big will it get?” Little seedlings can grow into awesome 100-foot giants. Don’t choose a size you’d have to keep amputating to live with. Better to go with a genetically smaller one. You’ll often have a choice between dwarf, semi-dwarf, and standard-sized trees. The big difference in the trees is the rootstock. If you decide to do your own grafting, you will be offered a choice of dwarf, semi-dwarf or standard rootstocks, and as the rootstock is chosen so the tree will grow.

Dwarfs are, of course, smaller, so most growers can spray, prune, or pick fruit easily. Dwarfs don’t need nearly as much room to grow as standards. If you have a small yard in a city, the obvious choice would be to divide the area among different kinds of dwarf fruit trees for as much variety as you could get for the given area. Many years ago dwarf trees were more expensive. That was when they were becoming popular and demand was greater than supply. Now at the nursery I go to, dwarf, semi-dwarf, and standards are exactly the same price.

Production Time/Amount. Somebody wrote and asked me, “What trees produce the fastest and largest quantities?” The answer is: not the same ones. That’s the big decision in dwarf versus standard. Dwarf trees bear fruit sooner. A standard apple tree may not produce fruit for 6–8 years, while a dwarf may in 2–4 years. (Apple takes the most time.) The fruit is the same size on either tree. However, standards produce the largest quantities of fruit per year per tree once they get going, and they will live longer than dwarf varieties. A dwarf tree will live for maybe 25 years, a standard tree for maybe 40. Semi-dwarfs are a compromise between the extremes. You have to make your own decision based on goals for your family and your orchard and then get the appropriate kind of tree.

Transplanting “Wild” Trees: Evergreen seedlings can usually be transplanted. In fact, curious but true, forest conifers that have already been transplanted once tend to have stronger roots and grow better when transplanted a second time. At the other extreme, most nut trees, wild or domesticated, have a central taproot that grows straight down. Any tree with that sort of taproot will not transplant successfully if the taproot is cut or broken off, or even bent over, when replanting. Thus nut trees over 6 feet are a high risk to transplant—whether from the wild or the nursery.
Tree/Fruit Propagation

Planning Your Orchard and Berry Patch: It takes a few years to get production going (unless you inherit mature plants). In the meantime you can compensate by scavenging for wild fruit and berries. Find out where they are and when. The general rule is to freeze berries and can fruit, but you may also can berries, or dry any of them. You'll want a good supply of canning jars. Figure on at least 80 qt. of fruit annually for a couple and 40 more for each child, and that's a desperate minimum. That's only 1 qt. a week per person during the 9 months when fruit is out of season. Then you can use rhubarb, strawberries, raspberries, cherries, and early apples to carry you until the later, larger fruits are ripe again.

Seedlings vs. Grafting: Nursery and mail-order trees may be seedlings or grafted trees. Seedlings have some definite drawbacks compared to grafted, or "named," trees. Grafting gives you the hardiness of a "native" (near-wild) rootstock combined with the fruiting ability of a highly selected variety of branch. So grafted trees usually have better weather or disease resistance, bear larger nuts or fruits, may bear more regularly, and yield heavier crops than seedlings, and are totally predictable in performance. With seedlings, you never know for sure what kind of tree or product you'll get because of its wide range of inherited possibilities; only about half, or less, of the progeny will probably be top-notch. You could wait a long time to find out if your tree is worth keeping. You can avoid that problem by choosing grafted (or budded) trees.

Grafting and Budding: To plant an orchard you may plant seeds, but usually you'll start by buying young trees from a local nursery or by mail-order. Eventually you might get involved enough to want to do your own grafting and budding. The main principle of grafting is that if you graft a Golden Delicious branch onto the rooted stub of another young tree, the future tree will produce Golden Delicious apples, even though the rootstock may have been from a different variety. Grafting techniques go back to the Romans, or maybe earlier.

To do your own grafting, you can buy rootstocks from a nursery or mail-order house. Or grow your own from seed. You could get prunings from neighborhood fruit trees to graft onto them. Any twig will do it. But the twig will fruit like the tree it came from. So you're probably better off buying top-quality plants for grafting or select from your own good-quality stock.

Grafting and budding are easily learned. Get a neighbor who does it to show you how or you could order the booklet Grafting Fruit Trees from Storey's, Schoolhouse Rd., Pownal, VT 05261. A wonderful book on this subject is Plants-a-Plenty by Catherine Osgood Foster (Rodale Press, 1977). Someone in your area probably offers a grafting course. Ask your extension agent, or ask around at nurseries. In this case, watching somebody doing it is the best way to learn. But in general:

To graft, cut off the top of a young rootstock tree. Rootstocks are selected to get roots that are resistant to disease, and hardy against cold winters, early frosts, poor soil, lack of moisture, etc. You can grow your own from seed or order it from a fruit specialist such as Adams County Nursery, PO Box 108, Aspers, PA 17304, which carries a large selection of rootstocks.

The fruit-tree part is usually chosen for abundant production of quality fruit. Select a whip or branch that has one or more buds. Cut off the bottom of that young fruiting tree. Make the cuts for both top and bottom in a matching zigzag so the fruiting top and rootstock will fit together tightly and firmly. Now fit the top into the bottom and bind them in place. Eventually they'll grow together.

If you're budding, the difference is that instead of cutting off the whole top of the rootstock, you place just one bud of the fruiting selection into and beneath a slit cut in the bark of your chosen rootstock. As new branches grow, prune away any that are from the rootstock rather than from the bud, or graft.

Grafting and Budding Definitions: A top (scion) from a plant with good heredity for fruiting is patched onto a bottom (rootstock) with good root and trunk qualities so they'll grow together and give you the best of both. Here are some other relevant definitions:

- Multi-stemmed: The plant will have more than one trunk.
- Rootstock: The bottom, root part of a graft combo.
- Scion: The top of a graft combo.
- Spur: This is a short special-purpose twig that certain fruit trees (apples, pears, etc.) grow flowers and fruit on.
- Stone Fruits: Apricots, cherries, nectarines, peaches, and plums have a hard cover over their seed—so they're the "stone fruits" or "drupes."
- Sucker: When the rootstock (or root) decides it wants to grow a top of its own and sends 1 or more new stems up, those are suckers. Suckers must be promptly cut off from a grafted plant or they'll take over. Some plants sucker a lot naturally (pawpaw and jujube), and will form a thicket if you don't keep the suckers cut back.
- Taproot: Certain trees have a large central root growing straight down from its center—way down. This is the taproot. The opposite of a taproot tree is one with a spread-root system. Taproot trees can pull up water from the water table so they're drought resistant, but they're hard to transplant once that root gets very long.

Propagation by Cuttings: A "cutting" is a piece of a parent plant that when planted on its own can develop into an independent plant. You can plant a cutting taken from the branches (a "stem cutting") or a piece of root ("root cutting") or in some cases you can even use a single leaf ("leaf cutting"). You can take a cutting from a dormant plant or from one that is actively growing in the spring and early summer. Later than that you are past the time for planting cuttings. Your planted cuttings need halfway agreeable weather, protection from getting dried out—keep them well watered until they take—and protection from curious children who would pull them up to see if they've got roots yet!

In general, for a shrub or tree-type plant, you cut off an entire branch of the previous season's growth (1–2 feet), or the end of a branch, or a sucker. Don't cut it off until the plant is in thorough dormancy, its leaves all dropped if it's deciduous. Plant the cutting, half underground and half above, in suitable soil for the type of plant in the place you intend for its permanent home, since transplanting is risky and stressful for the plant. When you want some berry or grape plants, or more berry or grape plants, you don't plant a seed—you plant a "cutting" of some sort.

Propagation from Suckers: Many berry runners travel under the ground like the nuisance lilac "suckers"
and then pop up anywhere to reach for the precious light. Various trees and shrubs put out suckers too. Any plant that suckers from the roots is a good bet for propagation by this method. In the spring you just dig up these nearly independent sticklike shoots, replant them where you want them, and with luck and care they’ll go ahead and grow.

**Tree Seed?** If yours is a grafted tree, this is not a good idea. If you plant a pit from your prized cherry or apple tree, the chances are significant that the offspring will have little in common with the parent. The offspring fruit, if any, might be very small and sour. The reason fruit seeds from grafted stock don’t breed true is because the top of the tree is usually grafted onto a hardier rootstock, but one whose seed may not have the fruiting capacity of the top part.

**Growing Trees from Seed?** The answer is that sometimes you can, and sometimes it’s practical. When it works, it’s certainly the cheapest, easiest way to get a tree. You just plant the seed wherever you want the tree to grow. There’s no expensive purchase, no transplanting, no early pruning needed. Growth from seed is how the great wild nut, fruit, etc., forests of the earth got planted and re-planted—by squirrels who buried nuts and forget where, or fruits that were carried away by hungry critters who consumed the tasty flesh and left behind the unwanted seed. Growing from seed does mean a few years longer to wait before bearing—and 99 percent of the time, growth from seed results in a plant not as big in quality as one you might obtain through grafting or budding from a plant with known, superior abilities. A tree that was grown from a seed is called “a seedling.”

In general: Wait to take seeds from the fruit until it is fully ripe, but don’t let them stand in fermenting juice an overly long time; that might kill the embryo. Dry the seeds and store them until late autumn. Plant 3 inches deep. The winter chill and freezing will break the seeds’ dormancy, and next spring they will grow. (Specifics are found below under each fruit.) Or order fruit tree seed to plant. You’ve a better chance of getting good heredity doing that.

**Buying Tree, Vine, Bush, or Bramble**

If you can, avoid buying fruit trees mail-order. Or buy mail-order from nurseries that are near where you live—or located in the climate zone where you live. The catalog salesmanship is great, but in the long run I think you’ll be happier with what you buy from a local nursery. The mail-order trees are cheaper. They are also smaller and rootstocks.

**Bare Root:** These are plants sold with no soil around their roots. They are usually deciduous perennials, dug while dormant. Bare root is an affordable and healthy way to buy.

**Genetic Dwarf:** This plant is a natural shortie and not a standard plant grafted or budded onto dwarfing rootstocks. Genetic dwarfs are smaller than plants on dwarfing rootstocks.

**Catalog Sources**

**NOTE: These sources primarily carry trees and fruits. General seed and plant suppliers are listed in Chapter 2. Very specialized nurseries are listed with their plant entry but are not listed here.**

**California**

Exotica: Rare Fruit Nursery ships one of the world’s largest selections of fruit trees worldwide. Their list includes acerola, Asian pears, bamboo, bananas of many sorts, carob, cherimoya, Surinam Chericitrus, coffee, curry leaf, figs, ginger, guavas, jujube, kiwi, loquat, longan, lychee, mango, mulberries, palms, papayas, passion fruit, persimmon, pineapple, quince, pomegranates, sapotes, star fruit, sugar cane, tamarind, pine nut, cashew, chestnut, ginkgo nut, Italian stone pine, jojoba, and macadamia; 760-724-9093; fax 760-724-7724; PO Box 160, Vista, CA 92083. Visit them at 2508-B E. Vista Way, Vista, CA; [www.bonusweb.com/exotica/](http://www.bonusweb.com/exotica/).

Pacific Tree Farms offers an amazing choice of subtropical and tropical plants and seeds: banana, citrus, guava, kiwi, mango, pomegranate, sapote, Surinam cherry, tea, etc.: 619-422-2400; 4301 Lynwood Dr., Chula Vista, CA 91910; [www.kyburg.com/ptf](http://www.kyburg.com/ptf).

**Midwest**

Southmeadow Fruit Gardens offers a very large collection of old, new, regular, and rare fruits. Free price list: 616-422-2411; Box 211, Baroda, MI 49101; [www.south meadowfruitgardens.com](http://www.south meadowfruitgardens.com).

**Northeast**

Adams County Nursery is a wholesale/retail operation that serves the northeastern U.S.: Michigan to Maine, south to Virginia. Their free catalog offers a large selection of rootstocks: apple, plum, sweet cherry, nectarine, and peach; and detailed, good instructions on pruning apple trees: PO Box 108, Aspers, PA 17304; 717-677-8105; fax 717-677-4124; [acn@cvn.net](mailto:acn@cvn.net); [www.acnursery.com](http://www.acnursery.com).

Brittingham Plant Farms sells strawberries, blueberries, raspberries, blackberries, and grapes. Great service!!! 410-749-5153; fax 410-749-5148; PO Box 2538, Salisbury, MD 21802-2538.

Nourse Farms specializes in small fruit plants: strawber ries, raspberries, blackberries, blueberries, currants, etc.: 413-665-2658; fax 413-665-7888; 41 River Rd., South Deerfield, MA 01373; [www.noursefarms.com](http://www.noursefarms.com).

F. W. Schumacher Co. specializes in seeds of trees and shrubs such as Christmas trees, etc. Good, conscientious folks. Details to plant each seed species on their website: [www.treeshrubseeds.com](http://www.treeshrubseeds.com); 508-888-0659; fax 508-833-0322; PO Box 1023, Sandwich, MA 02563-1023.

St. Lawrence Nurseries is an apple specialist, offering 100+ varieties and also specializing in fruits and nuts for northern climates (pears, plums, cherries, Juneberries,
grapes, blueberries, lingonberries, mulberries, raspberries, edible ornamentals, nuts, and timber trees, all raised in their own nursery). They also sell books, tools, and tree tags: 315-265-6739; 325 State Hwy. 345, Potsdam, NY 13676; trees@sln.potsdam.ny.us.

Northwest
Burnt Ridge Nursery specializes in unusual trees, shrubs, and vines that grow edible nuts or fruit: Carolyn and Michael Dolan; 360-985-2873; fax 360-985-0882; 432 Burnt Ridge Rd., Onalaska, WA 98570; burntridgetree@myhome.net; www.landru.myhome.net/burntridge/.

C & O Nursery is a wholesale/retail fruit-tree specialist; catalog: PO Box 116, 1700 N. Wenatchee Ave., Wenatchee, WA 98801; 509-662-7164; tree@co nursery.com; www.c-onursery.com.

Cloud Mountain Farm is a demonstration garden par excellence, a nursery that sells young fruit trees, and also a teaching facility: 6908 Goodwin Rd., Everson, WA 98247; info@cloudmountainfarm.com; www.cloudmountainfarm.com.

Columbia Basin Nursery sells fruit trees and rootstock, wholesale/retail. Brochure: 800-333-8589; 509-787-4411; fax 509-787-3944; Box 458, Quincy, WA 98848; cbn@televar.com.

Raintree Nursery offers 500 varieties of fruit, nut trees, bamboo, and berries: aronia, akebia, sweet gooseberries, currants, figs, persimmons, mulberries, lingonberries, alpine strawberries, pawpaws, etc. Free 88-pg catalog: 360-496-6400; 391 Butts Rd., Morton, WA 98356; info@raintreenursery.com; www.raintree nursery.com.

Van Well Nursery sells fruit trees wholesale or retail; catalog: 509-886-8189; 800-572-1553; fax 509-886-0294; PO Box 1339, 2821 Grand Rd., Wenatchee, WA 98807-1339; vanwell@vanwell.net; www.vanwell.net.

South
Vernon Barnes & Son Nursery offers fruits, nuts, and berries mail-order at bargain prices and good service. Free catalog: 931-668-8576; fax 931-668-2165; PO Box 250, McMinnville, TN 37110.

Cumberland Valley Nurseries sells fruit trees, wholesale and retail. Free catalog: 931-668-4153; PO Box 471, 394 Shaffie Lane, McMinnville, TN 37110; fruitrus@blomand.net.

Hidden Springs Nursery offers organically grown unusual and disease-resistant varieties including apple, pawpaw, mulberry, persimmon, and quince; catalog $1; 170 Hidden Springs Lane, Cookeville, TN 38501. No phone. No e-mail. Conscientious service from Annie!

Ison’s Nursery and Vineyard offers fruits, nuts, berries, and grapes, wholesale or retail; catalog: 800-733-0324; 404-599-6970; PO Box 190, 6855 Newman Hwy., Brooks, GA 30205; www.isons.com.

Lawson’s Nursery offers a free b/w catalog. Jim Lawson does his own grafting/budding. Trees: delicious quince, butternut, filbert, plum, fig, peach, pear, apple, grapes, gooseberry; walnut cracker; pecan trap (roll it across the ground and it picks up anything round!). Old-fashioned and unusual apples (more than 100 varieties): 770-893-2141; 2730 Yellow Creek Rd., Ball Ground, GA 30107; lawsonsnursery@aol.com.

Patrick’s Vineyard/Orchard Nursery specializes in nuts, fruits, and berries for Southern growers: 229-388-9999; 800-972-2101; Pomegranate Blvd., Ty Ty, GA 31795; www.tytyga.com.

West
Pikes Peak Nurseries sells retail and wholesale fruits, nuts, berries, grapes, etc.: 719-632-4751; fax 719-630-8902; 630 Abbott Lane, Colorado Springs, CO 80905; 1eland ppn@aol.com; www.pikespeaknurseries.com.

TREES TO REJECT
1. Any tree that can’t stand up without support.
2. Any tree with bark wounds on its trunk. (Look under the tree wraps.) Such a tree has a much lower chance of survival.
3. Any big tree in a small pot. An 8-foot tree with a trunk that’s 1 inch in diameter needs a rootball about 1½ feet in diameter to be healthy.
4. A tree with kinked or girdling roots. However, it’s hard to detect these because they are often deep within the rootball.
5. Species that are known to cause problems with dropping limbs, by raising sidewalks, getting pests and diseases, or perishing from climate extremes.
6. Look out for varieties that are merely ornamentals—such as “flowering almonds” or “flowering plums, quince, pears, etc.” They grow flowers, but not necessarily nuts or fruit.

How to Plant a Tree
In general, the best time to plant a tree is in the early spring or the late fall, but research your specific plant in case of exceptions. Where to plant is the spot where the tree will have the amount of sunshine it needs—full or partial, as specified; full if not specified. And, if it isn’t hardy, plant it where it will have shelter from the wind. Plant big deciduous (shade) trees on the south side of the house where they will shade in summer and let warming light enter your windows in the winter. Conifers do well as winter windbreaks on the north or windy side of the house. (Wisely placed trees can improve your home’s heating/cooling situation a lot!)
where the tree will have enough room, both for its above-ground growth and its rooting area. Imagine the full-grown tree 10 or 20 years from now. How close are walks, driveways, windows, houses, and cars?

- Keep in mind that fruit and nut trees can be a problem in the middle of a lawn. Mowers frequently damage young trees; or the droppings from mature and fruiting trees (especially nut trees) can damage mowers. The moistness of lawns can contribute to fungal disease in the tree. And the dense grass planting competes for food and water with your tree and will probably reduce the size of the harvest you might otherwise have from it. On the other hand, if the lawn is the only place you have, then do it anyway. Plant that tree!
- Don't plant under telephone lines unless the expected mature maximum height will be substantially less than the height of the wires (usually 25–30 feet).
- Watch for fire hydrants; sewer and water lines; and underground gas, electric, and cable lines. Most cities will send someone out to locate underground utilities for you for no charge—and be grateful that you cared enough to ask. Your phone directory or operator will tell you whom to call.
- Don't plant your tree where it will obscure a stop sign or make it impossible to see around a corner, or otherwise impair drivers' visibility. A big tree close to a street can risk impact between trucks and branches.
- Sidewalk planting strips less than 5 feet wide are not big enough for any but the smallest (mature height shorter than 30 feet) species of trees. Near a sidewalk branches can be a problem to pedestrians. And powerful roots can eventually buckle the pavement. Plant any larger-sized tree in the yard.
- There is a long-standing notion that tree roots don't go out beyond the drip line on the outer circumference of the branches and that they go very deep under the trees. Certain kinds of trees (nuts) do have very deep taproots. But all the trees tend to root more spread out, wider, and shallower than imagined. A lot of tree roots are in the top 18 inches of soil. Deep digging around them can harm those roots. That's why herbicides laid on a lawn may harm a tree at the edge of the lawn.

**DIGGING A HOLE:** Dig planting holes wide and shallow, no deeper than the rootball's size, and make them wider than needed to accommodate the tree's spreading roots. The larger the area that you dig up around the hole in preparation for planting the tree, the easier it will be for its roots to spread and find food and water. Remove any grass for 3 feet in diameter.

**Testing for Clay or Compacted Soil.** Dig a hole about 10 inches deep (a shovelful), and fill it with water. Check it again in 10 hours (overnight). Is it empty? If it has drained less than an inch an hour, you have a serious drainage problem.

**Soil.** Any kind of tree that needs “well-drained soil” is at risk to drown within 2 years if it's planted in compacted and clay-type soils—those that are poorly drained. Instead, plant tree varieties that are adapted to poor drainage—hardy plants that don’t specifically need “well-drained soil.” Or else rebuild the soil in a very large rooting area for your tree by working lots of organic material into the top 12 inches of dirt; or bring in better soil from somewhere else and create a large planting mound out of it. And dig wide: every inch of diameter dug out to the side before planting literally increases your tree's chances of survival in such difficult soil. It may also help to set the tree higher than usual in the planting hole. The sides of a hole in clay should be left with a rough surface rather than slick-cut by the digging tool. Don't work clay or saturated soils on the day you plant. Do your digging a bit ahead for the most normal soil structure to put the tree into.

**Built-In Special Drainage.** This is an option if you want to put a whole line of trees into a poor-draining area. Install “perf” pipe, or drain tile in gravel, and connect it to a storm drain. But don't put gravel under the roots!

**PLANTING THE ROOTBALL**

1. **Unpot the Tree.** Speed matters. Don't let the roots or rootball dry out. Care matters also. Don't let the roots or rootball break. Your plant either will be “bare-rooted” and wrapped in some sort of protective substance or will come with the roots in a ball of dirt in some kind of container to hold it together—a peat pot, burlap, wire basket, or bag. If it's a metal pot, cut off the pot with tin snips. Tear it off if it's made of paper. You have to get as much of the wrapping off as possible without actually harming the rootball. This may have you struggling with knives, wire cutters, etc. Untreated burlap can, if necessary, be planted with the tree.

2. **Double-Check Hole Depth.** Do this by setting the tree in the hole to see how it fits. The “collar” (or “crown” or “root flare”) should be just at soil level or a little above (to allow for mulch). Usually it's easy to see because you'll be looking for the same soil line that the tree had at the nursery. Trees planted too deep can die within a few years, or develop problems as many as 15 years later.

3. **Set Tree in Hole.** Then spread out the roots. If you see any girdling, damaged, or circling roots, cut them off. Try to lay the roots out in a way that they make good, straight contact with their new soil.

4. **Fill in Dirt.** Place dirt over and around it. Don't add anything to the dirt you're going to put back into the hole to cover the tree roots—not peat moss, not fertilizer. It does more harm than good to spurt fertilize a newly planted tree. This is because it tends to make the soil around the tree roots of a significantly different composition from the soil next to it. Water doesn't move normally across the difference. The result is a tree that's liable to be abnormally wet, or too dry. Don't bury incompletely decomposed organic litter around the seedling tree either. This can mess up the pH, the nutrient balances, and the populations of microscopic soil creatures. On the other hand, fully composted organic material that is evenly distributed across the top of the ground in your young tree's area could be helpful. Stomp dirt all around it to be firm and create a depression into which water can settle.

5. **The First Soaking.** When soil is dry, watering the tree as soon as possible after planting is critical for its survival. Use water also for the final settling of the soil. If additional settling occurs, add more soil, but don't step on the wet soil around the tree.

6. **Mulch.** Mulching the surface of the soil around your newly planted trees 2–4 inches deep does help them by controlling competition and gradually releasing nutrients. In nature, trees mulch themselves every fall. By keeping weeds away, retaining water, and moderating the soil tem-
perature, mulch improves the chances of survival for your tree. But never let mulch pile up against the trunk. After mulching the planting pit, brush back the mulch that is in contact with the trunk.

7. Avoid Staking. Natural flexing is necessary for the plant to develop a normally strong trunk and roots. Use staking only if needed to hold the tree up until the roots have become established (usually within a year). To stake, use 1 or 2 wooden stakes (pipe or rebar are too hard to pull out), which have been pounded firmly into undisturbed soil. Place the tie about a third of the way up the tree in order to allow maximum trunk movement. Use soft, flat tie material (inner tube, flat soaker garden hose, commercial products). Never use straight twine or electric, or any other type of wire, against a trunk. Remove stakes and ties as soon as possible. Trees are frequently girdled by ties that people forgot to take off.

8. Prune. But do not prune the tree top to “compensate for root loss.” That’s a myth. You may prune to take off broken, rubbing, and weak branches, but try not to remove more than 1/3 of the branches.

9. Dirt Dam. Build a circular dirt dam to create a basin effect around the outer edge of your tree planting area to retain water. Trees need water that soaks in deeply to establish good root systems. Water trees a lot the first year or two and during a drought. Let the root zone dry out between waterings unless your tree is a swamp variety. Five to 15 gal. a week is typical.

10. Care After Planting. Young trees benefit if they are irrigated, fertilized, and weeded, being a crop like any other. Water them at least twice a week. Regularly remove husks from weed and grass competitors. Or, easier and better yet, mulch around them so thoroughly the competition doesn’t get through. If your trees don’t grow well and aren’t an obviously healthy green color, they need fertilizer. Spread some manure from your barnyard. However, there’s such a thing as too much nitrogen, so spread it in reasonable amounts. For long-term care, young urban trees are most at risk for being bashed by cars or lawn mowers, or vandalized.

To Spray or Not to Spray: I think spraying is a vicious habit. It just creates ever more resistant insects and diseases, exactly the same way that super gonorrhea and super tuberculosis have been created by antibiotics. In a few decades fruit growers have gone from spraying once in a while for a specific problem to spraying regularly as many as 30 times a season. The pests they spray to kill just get more and more resistant because there are always a few that survive—the toughest, of course—and they pass their toughness on. Even organic fruit-growers tend to fall into the trap and call themselves “organic” because they spray only, maybe, 6 times a year. And they may spray on only petroleum (“dormant spray”), plus perhaps even some truly biodegradable and environmentally nontoxic botanics. It’s hard to roll over and play dead when something is eating your fruit crop.

The pendulum is swinging back now, with people more willing to accept some scars on the sides of the fruit and an occasional worm. If you can accept a reasonable amount of damage you can usually manage by using nontoxic control measures such as predator birds and insects, and planting resistant species. Another organic option, if your crop is getting wiped out anyway, is to take out the plants and burn them and plant other kinds of fruit that you can get a crop off of without poisonous chemicals.

I’d like to see that both government and private-party buyers adopt that policy. If a crop can’t be grown without massive use of poisons, it should be unrewarding to grow it. Environmental costs need to be charged as part of the product cost. If the pests are denied their usual diet, maybe they’ll become extinct. And anyway, then we won’t be poisoning the field workers, our air, water, and soil, and the fruit eaters on down the food chain. We won’t be messing up the balance of nature and breeding super pests trying to get a fruit crop past them.

So if your peaches can’t make it without spraying, I suggest you switch to persimmons and figs and kiwi and nuts and hardy berries. Same for apples, pears, or whatever. If everybody plants the same fruits and the same varieties of those fruits, a huge opportunity opens for any predator organism. There are so many lesser known fruits and varieties of fruits deserving of cultivation, which are not so troubled by pests. Give them a chance to perform for you!

PRUNING

In the first edition of this book, I was both very scared of pruning and very ignorant about it. Frank Reuter, Berryville, AR, wrote me these reassuring words: ‘A friend once told me, after planting several new apple trees, ‘Pruning just doesn’t seem natural.’ Having obtained the bare-rooted trees from a local nursery, she had dug them into the ground on a crisp, late autumn day. Then she hesitated. ‘There’s so little to start with, and I paid so much. I’d hate to cut anything away.’

‘“Look,’ I said, ‘do you want puny little apples seven years from now, or would you like to sink your teeth into a juicy, large apple in just a few years? I know cutting away branches on something you want to grow fast seems crazy, but experience has taught fruit producers again and again that careful pruning really does increase production.”

“But I don’t know how,” she worried. ‘I’d botch it for sure.’

“That’s the problem: knowing how. Pruning itself is not a difficult task, but it is complicated by the fact that there are so many different pruning situations. You don’t prune an apple tree like a plum, nor do a grape vine like a raspberry cane. I had another friend who put in about 15 blueberry plants and waited the long 6 or 7 years until they came into full production. For several years, blueberry pies became the field workers, our air, water, and soil, and the fruit eaters on down the food chain. We won’t be messing up the balance of nature and breeding super pests trying to get a fruit crop past them.

So if your peaches can’t make it without spraying, I suggest you switch to persimmons and figs and kiwi and nuts and hardy berries. Same for apples, pears, or whatever. There are so many lesser known fruits and varieties of fruits deserving of cultivation, which are not so troubled by pests. Give them a chance to perform for you!
A wonderful lady named Cass Turnbull has made herself the advocate for those who cannot speak, the trees. Her beat is an urban one, Seattle. Her self-defined mission is to fight pruning excesses and unnecessary killing of trees. Cass founded an organization, PlantAmnesty, which puts out a newsletter published for the fertile minds of PlantActivists—people who don’t beat around the bush. PlantAmnesty’s goal is “to end the senseless torture and mutilation of trees and shrubs caused by malpruning.” It carries “Adopt-A-Plant” and “Eco-Exchange” information. This award-winning little quarterly paper (16 pages, printed with soy ink on recycled paper!) can be yours for $20 per year regular, or $10 if you have limited income.

Cass never stops trying to get the facts out: “Most of us who have horticultural knowledge are frustrated that those who do the work, either pruning or planting, don’t have the same knowledge.” So she’s also the author of a book on how to do this necessary evil of pruning right: The Complete Guide to Landscape Design, Renovation and Maintenance: A Practical Handbook for the Home Landscape Gardener. Join PlantAmnesty or order her book ($17.50 postpaid) by contacting Cass Turnbull, 906 NW 87th St., Seattle, WA 98117, (206) 783-9813.

So the secret lies in between: some pruning, but not too much. And then again it depends on the plant, because some plants need a lot of pruning and some shouldn’t be pruned at all; and it depends on the time in the plant’s life, because plants are most likely to need “training” when they are very young, and then some should be left pretty much alone after that, but others need frequent attention. Plus no 2 people prune alike. So there are specific pruning instructions in the how-to-grow it section for each plant. And here are some basics.

Pruning Tools
Back to Frank: “When you shop for pruning tools, be forewarned: there is a lot of cheap stuff on the market. But bargain tools are likely to get dull in almost no time. Pruning requires you to cleanly remove a limb or cane, sometimes in a very tight space. If your equipment is not razor sharp, you will slash and tear your plants, leaving wounds or scars which invite disease and insects. With some garden tools, you can get by with less than first-rate equipment. But for pruning tools, be sure you are buying quality. When you are finished pruning, your plants should not look as if one of those whirring, mechanical, roadside-clearing tree slashers had a shot at them. Cuts must be made cleanly.” Cass would approve of that! Experience helps you know which tool to use for each cutting situation. Always use the smallest tool available. Only if it is not doing an adequate job do you move on to the next larger one.

**Basic Pruning Equipment**

1. **Snips:** Hand-pruners, “snips” (also called “pruning shears” or “hand clippers”) are your basic and most important tool. Be sure not to confuse this tool with a grass trimmer or a scissors-type shears. A hand pruner is an anvil-type instrument consisting of a sharp blade that snaps against a piece of metal.
2. **Lopping Shears:** Also called “long-handled pruners,” these are necessary for reaching higher limbs or for heavier cuts.
3. **Saw:** A pruning saw (a bow saw or a narrow, curved pruning saw) is used for thick wood that can’t be handled by the lopping shear. Such a saw can have a straight or curved blade, be fine- or coarse-toothed. A bow saw has the advantage of giving you leverage; a narrow curved pruning saw is better for getting into tight places. Incidentally, the saw will be your least-used tool. Never cut large branches unless you have a good reason. A “good reason” would be because a branch is diseased or dead.
4. **Pole Pruner:** This tool is useful if you have standard or semi-dwarf trees and you find it necessary to prune beyond the reach of your lopping shears. These are clippers mounted on top of a pole, activated by rope or spring.
5. **Hedge clippers:** For home fruit-tree pruning, don’t use hedge clippers or a chain saw. Hedge clippers are intended only for very fine twigs, and chain saws produce too rough a cut.

**Sharpening Pruning Tools:** Frank says: “In general, always keep them sharp and clean. Sharpen pruners or shears as needed the same way you sharpen a pocket knife: Use an oiled whetstone. Place the blade on the edge of the stone with the cutting edge facing away from you. Tilt the dull side of the blade toward you, making sure that the cutting edge stays in contact with the sharpening stone. Then draw the blade toward you. Repeat until nicks and cuts disappear and the blade again is sharp to the touch. If your whetstone is fairly large, you may have to disassemble a pair of hand pruners. If you must, do what all smart mechanics...
do when they take anything apart: make a sketch of all the pieces and their position relative to each other so you can put your shears back together again. Saws, of course, are a special case. If your saw gets dull, either purchase a new one or pay a professional to sharpen it.

**Winter Tool Storage:** “To prevent rusting and corrosion of your tools, lubricate them lightly with oil, especially if they have to be kept in a damp place.” If your tool becomes gummed up with sap or pitch, use kerosene sparingly to clean it.

**How to Prune**

Cass let me borrow heavily from her book on pruning for this section. So, if it sounds like I know what I’m talking about, that’s the reason. In addition to the information here, you’d find Cass’s entire book helpful. Also you can get bulletins from your local extension service, get other books, and take classes. Pruning can get really complex, and pruners don’t necessarily agree with each other about even basic principles. There’s a lot more to it than learning how to spread open young limbs (some people use clothes-pins) or to shore up old limbs with 2 x 4s to keep them from breaking.

**Tree Surgeon’s Hygiene:** With fire blight in mind, Frank advises: “Certain plant diseases can be passed from one plant to another on your pruning tools, so clean them periodically while you work. Use a rag soaked with a bleach and water solution (1 part bleach per 10 parts water) to . . . wipe the cutting surface of your tools. For small jobs, you can use a paper towel soaked in isopropyl alcohol, which is the ordinary rubbing alcohol and available in a drug store. If you are making cuts on plants which are clearly diseased [like fire blighted], clean your tool after each and every cut to prevent spreading the disease to healthy plants. And, of course, after every pruning job, clean your tools with your cleaning rag before storing them away. Also clean them with your sterilizing solution before beginning any job; someone else may have used your tools on a diseased plant without you being aware of it.”

**How a Tree Heals:** Research suggests that none of the “wound healers” on the market really help much. A tree does its own healing, and it heals by creating a barrier against the injury that rot won’t get through. A tree doesn’t fill in the wound with replacement living tissue the way people do. It just puts a wall in there and does the best it can with what’s left at that site. So leave a “rotten” hole in a tree alone. Don’t gouge at it. Because under the rot is the layer that stops it, and you don’t want to cut that open.

**Pruning Away Fire Blight:** Fire blight is a misery of a disease that can afflict many temperate-zone fruit trees. If it’s a problem in your area, prevention of fire blight is a 3-part program: First, avoid feeding excess nitrogen to fruit trees because succulent young growth makes them more likely victims. Secondly, avoid any but the most necessary pruning. Finally, avoid unnecessary watering. Keep an eye on your trees, especially from bloom until fruit, because next to prevention, early detection to bring fire blight quickly under control is the best.

If blossoms, twigs, and leaves on your tree die and turn black but stay on the tree, you have a case of fire blight. You may also see mummified fruit and cankers. The cure is a radical pruning away of all the infected wood. Inspect carefully to identify all branches that are infected. They are a total loss. In addition, cut a foot beyond the infection because the bacteria tend to be working somewhat ahead of where their damage is visible. Keep in mind that the branches, leaves, even twigs that you’re taking off carry the problem organism, so don’t handle the blighted areas and then touch the healthy tree. Keep the blighted cuttings away from the tree. As soon as you have them off, move them well away from any orchard trees. Burn them in a hot fire so they won’t spread disease. And disinfect!

But hopefully, all your pruning will just be routine procedures.

**Pruning Definitions**

**Whip.** This is a young tree that has no branches, or one that someone made to look like that by cutting back all the branches to the main stem, leaving the top intact but no side branches.

**Pinch.** It is less stressful for a tree to have new sprouts pinched off as they form rather than pruned off when they are larger. Pinching maintains all the leaves possible, which helps to feed the tree, yet halts all unwanted new growth. But this method takes much more time than pruning since you have to pinch regularly during the first few weeks of new growth.
Apical Dominance. The last bud on the end of a branch is called the “terminal bud.” It releases a chemical that travels by gravity and keeps the other buds on down the line rather subdued. It’s the boss bud. That’s called “apical dominance.” When you cut off the terminal bud (or even pull it over), the chemical flow is disturbed. That causes the other buds to begin to grow.

**Timing:** Here’s Carla’s simple system for pruning: Don’t prune any the first year. After that, you can prune once in the spring and again in the fall. Prune when the leaves are off the tree. Don’t remove the lower branches of dwarf trees; there won’t be any higher ones. Here’s Cass’s much better simple system for pruning!

Pruning of young fruit trees (under 6 years) is done to develop strong, low framework branches and not much else. In fact, it may take a while longer for your tree to fruit. Go easy in the early years. Don’t prune too much (no more than ¼ total leaf surface) in any year. Old trees can be invigorated by heavy pruning to produce new wood and spur systems, although you may experience a temporary drop in production when you cut off older and lower limbs. But don’t try to fix it all in 1 year. If you have a tree of any age that needs a lot of work, do it over several years.

Summer pruning of fruit trees is all right if the tree is vigorous and healthy and well-watered. Summer pruning can be useful for spotting dead wood (no leaves). It can be useful in reducing the spread of fungus-bacterial diseases that like damp weather, and it will help reduce suckering. It generally slows the growth rate and will help restrict the size of your tree. But summer pruning is harder on the plant, so go easy.

**NOTE:** Never prune during a drought.

**Basic Pruning**

1. First, and always, take out all of the dead wood.
2. Take out the worst crossing, rubbing branches.
3. Take out the worst wrong-way branches. These are the ones that start on one side of the tree, head the wrong way through the center, and come out on the other side.
4. If you have a grafted tree, carefully prune off any suckers growing up from the roots or out from around the base of the main stem below the graft line.
5. Take out some, not all, of the suckers and watersprouts. (Fruit trees can develop a whole bunch of shoots—suckers or watersprouts, reaching for the sky.) Cut some out altogether. Leave some alone (don’t cut off the tips), since they will flower and fruit and be pulled over and produce more spurs later. Head back some suckers to thicken them up into second-story branches. Try to head back to another upright side branch and not to a horizontal branch that would sucker back madly. Thinning back some of the branches, especially toward the top (even a few big branches) increases light penetration and lowers your tree. This helps ripen the fruit lower down. It increases air circulation, too, which is important in order to discourage the numerous bacterial and fungal diseases that spoil the fruit.
6. The conventional wisdom for regular pruning is to remove weak crotches. Both horizontal connections and very narrow crotches may be vulnerable. The preferred connection is wider than a 45-degree angle, but less than a 90-degree one.
7. But to encourage more fruiting on your apples and pears, prune for more horizontal branches. Horizontal branches bear more fruit than vertical branches. You can head back laterals to force more spurs to form.
8. Mature fruit and nut trees can be pruned to let more light into the tree. That will make for larger, better harvests.
9. Too much pruning can weaken your fruit tree enough to result in sickness.

**Removing a Tree Limb.** First find the “branch collar.” That’s a little doughnut-shaped bulge at the base of the limb. Don’t cut so flush that you cut through the middle of the branch collar. Cut just out from it. That will end up
Pruning for Fruit Production. Certain kinds of branches make more fruit buds or spurs than others. These are the ones that are situated in a not-too-horizontal position. You can pull or push new branches into such a position, or you can just start cutting out the ones that aren’t in the right place and leave the ones that are. Nature makes fruit by sending up a young, straight-up soft branch. It flowers on the tip, and the flower turns into a fruit. The weight of the fruit pulls this supple branch over. As a branch gets older, it stiffens in a more horizontal position. As the branch tips over, the apical dominance of the terminal bud weakens, and buds farther down the branch are released to form nice little side branches (laterals) and on them, teeny, tiny ¼-inch branches called “spurs.” These spurs have fat flower buds (fruiting buds) rather than skinny leaf buds. We want the laterals and spurs.

In the winter, it is the fat-budded spurs that you see on trees that make you think what you’re looking at might be a fruit tree. You can encourage some, but not all, of your side branches (laterals) to make spurs by heading (also called “tipping back”) to 2 or 3 buds. This works on pears and apples, but it doesn’t work on cherries.

If your main branch gets pulled too far over—past 90 degrees—apical dominance is diminished, too many buds are released, and those miserable suckers start charging back up. In some senses pruning fruit trees breaks all the rules for ornamental tree pruning. You try to keep your tree short with pruning. No topping, no heading of lateral branches (laterals) to encourage fruit spurs, and prune medium.

Pruning Errors: The most common errors when pruning fruit trees are, first, topping and, second, creating umbrella trees. Topping is bad for any tree, including fruit trees. The suckers that shoot back up from a topped fruit tree not only will be ugly; they are also too busy trying to get enough leaves back in order to feed the tree to make much fruit.

Dealing with Suckers. You may have a forest of suckers that are the result of previous bad pruning. If you remove all of the suckers, they all come back. So leave some to dominate the rest, shorten some to create a second story up, and thin out the rest. The reason why you “leave some to dominate the rest” has to do with that botanical phenomenon of apical dominance.

Reducing the Height of an Apple or Pear. As you work, keep in mind apical dominance. Thus, it is a good idea to cut back a tall vertical branch to a shorter branch that also faces upward. Basically you are not trying to eliminate all vertical branches; you are simply replacing them with shorter, younger, and fewer vertical branches. This retains some apical dominance and allows the tree to grow a little every year. It’s like a volleyball game—you rotate out a few of the tallest old suckers every year.

Instead of topping, many orchardists choose to reduce the height of apple and pear trees using the “drop-crotch” method of lowering trees. Drop-crotch means you selectively head back to a side branch of a decent size, say one–half the diameter of the parent stem. This is hard on the health of old trees and opens them up to rot. Trees 15 years or younger withstand this height-reduction better. Drop-crotch reduces the amount of sucker growth, as compared to topping, but does not eliminate it.

Umbrella Trees. Don’t create umbrella trees with ugly, sucker-laden crowns. An umbrella tree is made when the pruner cuts to an outside branch year after year, which is called “bench-cutting.” But the typical state of many old fruit trees is an umbrella, which is all right if the umbrella is low down on the tree where you can get the fruit, and if you don’t care how it looks. But often the umbrella occurs high up on the tree, shading out the fruit below. In that case, you’ll want to fix it. The problem is terminal buds that are too low. Gravity prevents the chemical from reaching buds down the line, so a crown of suckers develops at the top. To help keep your old apple tree from excessive crown suckering, thin back low branches to get a branch facing more up and out. To do that, pick out a major (scaffold) branch and follow it with your eyes. Does it dip down quite far, crossing other, lower scaffold branches and cluttering things up? Then you may selectively head back (prune) to one of its side branches that faces more upward and outward (40–60 degrees is ideal). The scaffold branch now ends in a boss bud with greater apical dominance. This will reduce the number of returning crown suckers farther back as well as improve the looks of your tree.

Grafting: To learn how, watch a neighbor do it, take a grafting course, hang around at a nursery, or read Grafting Fruit Trees (Storey’s: 802-823-5810; www.storey.com); or Plants-a-Plenty, by Catherine Osgood Foster.

Sugar Trees

Maple Varieties: You can gather a sweet sap from just about any maple variety although the sugar maple, Acer saccharum, is most frequently tapped. If you live in a state bordering any one of the Great Lakes or in the Northeast, you should be able to grow sugar maples and tap them. You can grow them other places too, but tapping won’t be as successful. Your altitude is an important factor. Between 600 feet and 2,500 feet is best for sugar maples. For good sap production your climate has to have a big difference
between day and night temperatures in the spring. Maples don't produce much sap where winters are mild.

There are other sweet-sapped maple varieties besides the sugar maple that will grow from California on north to Alaska, and they grow over much of the eastern United States south to Alabama and north to southern Ontario and Quebec. The black maple is almost as good to tap as the sugar maple. The Norway maple comes in right behind the black. The sap of red maples has only half as much sugar as that of the sugar maple, and the syrup isn't as fine, but it can be used. The Rocky Mountain maple, big-leaf maple, silver maple, and big-tooth maple all may also be tapped.

Sugar maples are excellent summer shade trees and glorious in the fall with red, yellow, and orange leaves that make the ground look like it's covered by cool fire. They're hardwoods that grow 50–100 feet tall.

Sugar maples aren't the kind of crop you cash in on in a hurry. They are planted more for your successor than for you because they take so long to grow—about 30 years or more to get large enough for tapping. And if competition for space is tight in your planning, also keep in mind that each maple tree will produce only about 1 or 2 qt. of finished syrup per year. So it may not be worth it to you—or to your successor.

PLANTING AND GROWING: Sugar maple seed is available from William Dam Seeds (905-628-6641; www.damseeds.com), and it's okay to grow them from seed. Or propagate by budding. Country Heritage (PO Box 536, Hartford, MI 49057) sells 4–5 ft. started trees. In the West, Burnt Ridge Nursery sells them. Don't prune your sugar maples much. They produce best if they have lots of branches.

Trees spaced 35–45 feet apart produce the most sap, but keep some young ones coming in between there as eventual replacements. One way to thin maples is to use a portable sap tester, which tells you the sugar content of each tree. Then you can thin out the less-sweet trees. Another option is to plant your maples both for tapping and for timber. In that case put them 20 feet apart. Less sap but more trees to tap will add up to the same sugar harvest, and you'll have a bigger eventual timber harvest.

MAPLE SUGARING INFO/SUPPLIES: Storey's offers a booklet, “Making Maple Syrup,” and a book, The Maple Syrup Cookbook (802-823-5810; www.storey.com). Check out The Maple Sugar Book, by Helen and Scott Nearing, and Syrup Trees, by Bruce Thompson (1978). Sugaring supplies of every sort, books, and a free catalog are available from Leader Evaporator Co.: 802-524-3931; 802-524-4966; fax 802-527-0144; 25 Stowell St., St. Albans, VT 05748; sales@leader evaporator.com; www.leaderevaporator.com. A person can spend almost nothing or thousands of dollars on sugaring equipment, depending on your inclination, how many maples you're trying to keep up with, and whether you are producing for home use or for commercial sale.

Incidentally, don't expect your homemade syrup to taste just like store syrup, which is merely flavored with the real thing. Maple syrup is the most expensive natural sweetener on the market—because it takes so much sap to make a gallon of syrup (33–40 gal. at 3 percent sugar content), the tapping season is short, and the trees give but not copiously. But if you have maybe 14 or 15 trees to tap, you can have a nice home-sugaring operation.

IDENTIFYING SUGAR MAPLES: Since you're most likely to be tapping from trees that you didn't plant, you may not even be sure if you have sugar maples and which of your trees they are. In yards, you'll have to distinguish the sugar maple from the Norway maple. In the woods you'll have to distinguish it from the red (or soft or swamp maple). In that case get somebody who knows to point them out to you and put a splash of bright paint on each designated tree so you don't forget. Even an experienced mapler, however, may have difficulty distinguishing sugar maples in winter and spring. Fall is the easiest time. So be sure and get your trees to be tapped marked before fall is over, while their distinctive foliage is still on.

TAPPING MAPLES

When to Tap. You tap your maple trees in early spring, around the first March thaw, generally mid-March to mid-April. Be careful not to tap prematurely. Some old-timers suggest to tap 1 month before your snow is usually gone. You can get some sap in the fall or any warm winter day but not nearly as much as you will during the spring run. The important determinant isn't the calendar; it's the thermometer. The right weather is a freezing night followed by a sunny day, with a temperature of at least 40° F. Take wind-chill into account: more wind requires a higher temperature. It's traditional to try to get all your buckets up in one day.

As soon as you have tapped, the tree goes to work healing the wound and closing off your supply—takes it about 4–6 weeks. If you accidentally tap before the weather has really settled into a spring pattern and the days turn freezing again, your sap supply will temporarily stop and you'll lose some tapping time once it does start to run again.

How to Tap. In addition to tapping the right kind of tree, you need to tap a tree of the right size. Don't tap a maple that is less than 10 inches in diameter. For each 6–8 inches of tree diameter more than 10, you can add 1 tap, as many as 2. (Newest research shows you should limit yourself to 2 taps per tree.) The hole in the tree is bored with a hand drill about 2 feet up from the ground (the lower, the better) and about 2 inches deep. (The hole has to be deep enough and the spout placed in it firmly enough so that even a heavily loaded bucket won't pull the spout out.) If the hole into the tree is angled slightly upward, it will help the sap run out. Sugaring suppliers sell 3/8-inch bits, which match the size of most commercial spouts. But a 3/4-inch or 1/2-inch bit can be made to do. New tapholes are drilled every year.

Ann Moran wrote me: “Sap shows in the end of the twigs, usually in late winter if the winter was mild or in the earliest spring. The hole in the tree is bored with an auger. New tapholes are drilled every year and into each hole you insert a hollow metal spout and from that you hang a bucket. A really big old tree can have as many as four buckets on it. So the sap goes up the tree trunk and out the spout and down into your old-time bucket and then every day you should collect the drippings from each tree and take them to the sugarhouse for boiling down. If you've only got one tree go ahead and tap it. Boil the sap down on your kitchen stove and you'll have about a pint of maple syrup. It takes a lot of sap to make syrup.”

Into each hole you hammer in a hollow metal spout with a sequence of light hits, and from that you hang a bucket. Be careful not to hammer so hard you split the bark. Sap would leak out through such a split and be wasted. This spigot can be homemade out of wood or a
piece of metal pipe or purchased quite inexpensively from a sugaring-equipment source. Manufactured spouts are made with built-in hooks to hold a bucket firmly on. Your first taps should be on the south and east sides of the tree. Then tap west and north. (North-side taps are last to begin flowing, but they’ll also be last to stop.)

If you are tapping from a tree that has been tapped within the previous 10 years, place any new tap holes at least 3 inches to the side of and 6 inches above or below the old holes. That’s because a tap hole causes death of the inner bark in an oval pattern around it, the oval being a couple inches to each side of the hole and a few inches above and below it. It takes 10 years for the tree to heal that place completely.

**How to Collect.** So the sap goes up the tree trunk and out the spout and drips down into your bucket. What can you use for the bucket? A coffee can, plastic milk jug, or a specially designed bucket. (If buying used buckets, beware of beat-up or rusty ones—they probably leak.) A larger container will need to be emptied less often. A commercial bucket will hold 4 or 5 gal. of sap. The bucket needs to be protected from sugar-loving animals, and from rain, snow, and wind-blown debris like dirt, leaves, and bugs. The easiest protection is a lid, which is an attachment you can buy and use for a commercial bucket, or you can devise your own.

Then every day you should come by each tree with your gathering pail into which you’ll empty the spout buckets. Take the full gathering pail to your chosen site for boiling down. You may need to collect more than once a day on the best days.

A modern collection system for trees that are reasonably close together and uphill from the boiling place is plastic pipeline that picks up the sap at the spout and carries it directly down to a holding tank. It’s inexpensive and easy to collect with but inconvenient to clean after the season’s end. It’s also difficult to notice a tree sending in bad sap, and the set-up is attractive to wild critters who’ll like to take a bite and help themselves to the sap.

Freezing can shut down a plastic pipeline that has a slack and low place in it. It doesn’t hurt the sap at all to freeze, either in the bucket or elsewhere, before you get around to boiling it. An interesting thing about partly frozen sap is that as the sap freezes, the sugar tends to stay in the liquid part. A bucket of sap half frozen would have a sugar concentration in the liquid part of twice the usual, the equivalent of half your boiling time accomplished already. But the frozen lump does have some sugar in it, although a proportionately lesser amount.

### When to Stop Tapping
1. Before the leaves go into bud (see step 4).
2. If you get tired of boiling sap before that (just pull the spouts out of the trees and you’re done).
3. If the sap stops flowing.
4. If some sap is a pale to bright yellow color (a sign that the tree is ready to bud and no good for syrup-making).
5. If the finished syrup is dark brown rather than amber, with a strong, unpleasant flavor (it’s edible, healthy, but not the kind of syrup you can give for a present).

#### The Boiling Down: At your boiling center all the individual buckets are emptied into a holding tank—maybe a big plastic garbage can. This should be outside in a cold place (north side of a building). Or pour directly into your big kettle, like a canning kettle, or one of the large, flat-bottomed pans specially designed for this process. Galvanized pans are not recommended. You can boil the sap down in any pot and on any source of heat. But if you use your kitchen stove and if you are boiling very much of it, it makes the house damp and steamy. Large producers boil in a “sugarhouse,” which is a separate building—as simple as four corner posts with a roof or as fancy as a wooden building with windows that open and/or a steam vent in the roof. It’s helpful to make it large enough to keep a dry wood supply right in there, too. Holes in a sugarhouse wall help to let the steam out. Either way it’s nice to have a level floor. Another choice could be a fireplace or outdoor stove in your yard, possibly made of cement blocks. It helps if your boiling place is near the maple trees but at a lower elevation.

The sap you’ve collected looks and tastes like sugared water. In fact you can drink it straight, or use it to sweeten other drinks or in cooking.

#### Beginning the Boiling. Boiling down the sap is a long process, and it takes a lot of sap to make syrup. It takes a 6-gal. kettle of sap 4–5 hours of boiling to turn from sap into syrup—about a quart of it. Thirty to 35 gal. sap would boil down to 1 gal. of syrup. Jean Nance wrote me from Neoga, IL: “We make maple syrup in small batches, from 10 maple trees. If you have 8 qt., you are going to get about 8 oz. of syrup. Until the volume is down to perhaps 16 oz., you are essentially boiling water and don’t have to watch it at all. The last bit of boiling down does have to be watched carefully. The main problem is steaming up the house—everything drips!”

A rule of thumb is that while boiling down from the start to \( \frac{1}{10} \) the original volume, you don’t need to watch it. From \( \frac{1}{10} \) to the final stage (\( \frac{1}{50} \)) though, you do have to pay attention. At this stage later sap begins to develop a layer of thick white foam on the top. (Beginning-of-the-season sap is less likely to foam and boil up.) Skim off that foam with a strainer and discard it; wear a leather or rubber glove while skimming. Boiling up (and possibly over) is a problem related to the physics of surface tension; just add a drop of cream and it will go back down. (Without the drop of cream, you won’t be able to boil it as hot and fast for fear of the boiling up.)

Once begun, the boiling-down process should proceed promptly. Sap that stays in the pan too long darkens in color and gets a heavy flavor. But it is fine to add more sap to a batch that is already in the process of boiling down.
Testing the Syrup. You can test your boiling sap for density with the regular sugaring tests or with a hydrometer, sugar thermometer, or candy thermometer. Boil until your candy thermometer shows 219°F at sea level. For every 550 feet above sea level where you are, add 1 degree Fahrenheit to that temperature. An easy old-time test: Unfinished sap will drop back into the pot off an ordinary spatula that has been dipped into the boiling sap, but finished syrup will cling to the bottom of it.

If you intend to sell your syrup you need the equipment to get it to exactly the correct density and labeled with its grade, available from a sugaring supplier. For commercial markets maple syrup is graded by established standards for color and density. The lighter amber the better grade. Dark-colored syrups have a caramel flavor rather than a maple flavor.

Maple Sugar. You will make maple sugar if you don’t watch the boiling sap carefully in its last stages. If allowed to get even slightly too dense, the syrup will gradually, over the succeeding months, precipitate out rock-sugar crystals, which will collect on the bottom of your jar. These crystals are hard and tasteless. It’s safer to stop a little short of the ideal density than to let your syrup go a little past it.

On the other hand, if you deliberately want to make a maple candy, then pour some of it onto clean snow. When it’s close enough to done it will cool on the snow into a glasslike rock sugar. To make the whole amount into candy, then pour some of it onto clean snow.

If allowed to get even slightly too dense, the syrup will gradually, over the succeeding months, precipitate out rock-sugar crystals, which will collect on the bottom of your jar. These crystals are hard and tasteless. It’s safer to stop a little short of the ideal density than to let your syrup go a little past it.

On the other hand, if you deliberately want to make a maple candy, then pour some of it onto clean snow. When it’s close enough to done it will cool on the snow into a glasslike rock sugar. To make the whole amount into candy, then pour some of it onto clean snow.

Straining the Syrup. If you skip this step, you’ll have debris in the bottom of your syrup that you’ll have to discard after the clear syrup above it has been poured off and used. So, after the syrup is completely boiled down, strain it through flannel or a paper coffee filter to remove that debris. Or use a commercial felt strainer.

CANNING MAPLE SYRUP If you filtered it, you have to put the syrup back on the heat and bring it back to a boil. Then pour it boiling hot into clean jars or any other sterilized container that you can get a really tight lid on. Pints are a good size for this precious stuff. Fill to very near the top of the container. Then lay the sealed container on its side so the top gets sterilized too. Some people use a paraffin dip. If your syrup isn’t carefully canned, it will get moldy. Refrigerate after opening.

MAPLE SNOW CANDY Marlissa Carrion wrote me from New York about her childhood in Ohio: “When Mom and my aunt would be heating maple syrup, we used to run out in the yard in the winter with a big roaster pan and scoop up fresh-fallen snow in it. Then we’d trail ribbons of maple syrup into the cold snow. It would harden to a kind of candy.”

CANNED MAPLE-WALNUT ICE CREAM TOPPING Mix together in a saucepan 1 c. maple syrup, 1¼ c. corn syrup, ½ c. water, and ½ c. sugar. Boil, stirring once in a while. After it has commenced boiling, add 2 c. walnut pieces, stir in well, reduce heat to a simmer, and let cook 15 minutes or until thick enough to suit you. Then ladle hot syrup into hot jars. Leave ¼-inch head space. Put on lids. Process 10 minutes in a boiling water bath canner.

OTHER SUGAR-SAP TREES: Sugar maples are the best known, but not the only sweet-sap trees.

Palm Sap. Palms are the tropical-zone sugar-sap tree. In the blooming stage they send energy to the flowering and soon-to-fruit high part of the plant in the form of a rich, very sweet sap. To tap it, you must climb the trees all the way up to the flower stalk, which is located high in the palm’s crown. Cut it open and establish a drainage arrangement. The flow of sap can be continued for weeks by cutting open the flower stem each time it heals shut. Pounding on the tree can help, too. A palm tree being tapped for sweet sap will not produce nuts as long as it’s being tapped for sap.

Butternuts and Birch. Butternut trees can be tapped in the same way like maple trees and their sap boiled down to make a sweet syrup. Birch trees (even in Alaska!) can be tapped for syrup. Black (sweet) birches give lots of sap. Tap in April, same as for maple. Birch sap is less concentrated than maple sap, but if you boil it patiently enough you get your syrup. Use same directions as for the maples.

NUT TREES

Enter the Wonderful World of Nuts!

If you live where nut trees grow wild, you can bring home bags of nuts for free. But there are fewer and fewer wild nut trees. So consider planting some. Nuts provide fat, protein, and, in the case of acorns, carbohydrates. Most seedling nut trees take 5–10 years, or longer, to bear, but once started they continue producing crops year after year with practically no care—as well as providing a bonus of beauty and shade. World-wide there are nearly 1,000 kinds of nut trees, but in North America there are relatively few types, each with distinct climate requirements. So what nut varieties you can grow depends above all on where you live.

CLIMATE: If you live in Southern California you can raise macadamia nuts. In North Central California, almonds and Persian or Carpathian walnuts are primarily grown. If you live in the Southwest, you can grow pine nuts; in the Southeast, pecans. California, Oregon, and Washington grow fine filberts, hazelnuts, and Persian or Carpathian walnuts. The Northwest is excellent for chestnuts. Black walnuts can be grown well in the central and eastern United States. Nut tree nurseries, agricultural universities, and individuals are constantly working to develop improved varieties of each nut. Incidentally, peanuts are not technically a nut, but rather a southern-suited legume, a member of the pea family.

NUTS FOR SALE: The best-selling volume market nuts from wild trees are pecans and black walnuts. Statistically, almonds are the number 1 nut grown and sold in the United States in terms of volume produced, followed by Persian walnuts, with pecans coming in third. Chestnuts and pistachios are right up there too. Commercial nut growers must invest in expensive machines that shake trees and other machines that pick up nuts, as well as drying and storage buildings, grading, shelling, and packing.
equipment. But there are also nut growers who make a living using very old-fashioned production and processing methods.

**Nut Timber:** Some nut varieties, especially black walnut, are grown for their valuable timber. To do that, plant closer than for an orchard and prune to a strong central leader. As they grow taller, every fall cut off several of the lower branches until you have an 18–20 feet trunk or “bole.” Allow at least 2 times as much branched area on the trunk as limb-free trunk. It’s better to cut those lower limbs (making a straight, valuable trunk) while the tree is small and young rather than later when the wound may be larger and may never properly heal over, resulting in a scarred trunk. Butternut, black walnut, chestnut, and pecan woods are particularly prized for making paneling and furniture.

**Nut Books:** Look in your library for *Nut Tree Culture in North America* (Richard A. Jaynes, editor), which offers a wealth of information for serious nut growers. “The Annual Report” (1910–present), put out by the Northern Nut Growers Association, contains lots of nut culture info. Other good sources are *Nuts for the Food Gardener* by Louise Riotte (Garden Way, 1975), and *The Improved Nut Trees of North America* by C.A. Reed and J. Davidson (1958).

I’ll describe only about 20 nuts in this book, a fraction of the world’s nut-bearing plants. Read about the rest of them in *Edible Nuts of the World* by Edwin A. Menninger.

**Nutworking:** These organizations welcome questions from amateurs. 

**Illinois Nut Tree Association:** Robert Adams, Treasurer; 309-367-4650; RR 3, Metamora, IL 61548-9310.

**Kansas Nut Growers Association:** William Reid, Secretary; 620-597-2972; PO Box 247, Chetopa, KS 67336.

**Nebraska Nut Growers Association:** Todd Morrissey, Treasurer, 402-472-3674; 122 Mussel Hall, East Campus, U. of Nebraska–Lincoln, Lincoln, NE 68583-0714.

**Northern Nut Growers Association:** members include commercial nut growers, nut scientists, and amateurs. Visit their website for nut tree info and to ask questions of an expert: www.nutgrowing.org. NNGA’s Membership Directory, quarterly newsletter, *The Nutshell*, “Annual Report,” access to the lending library, and an invitation to the annual meeting—all for $20/yr: Nancy Pettit, Treasurer; 302-659-1731; fax 302-659-1732; PO Box 550, Townsend, DE 19734-0550; chestnutsunltd@email.msn.com.

**Pennsylvania Nut Growers Association:** Tucker Hill, Assistant Secretary, edits PNGA’s newsletter, *The Nut Kernel*, and is the person who answers questions. I am indebted to him for reading this section, painstakingly correcting my errors, and supplying valuable info: call/fax 717-938-6090; 654 Beinhower Rd., Etters, PA 17319-9774; tuckerh@epix.net.

**Society of Ontario Nut Growers (SONG):** a Canadian association of nut growers interested in hardy nuts and good publications: Ernie Grimo, Treasurer, RR 3, Niagara-on-the-Lake, Ontario L0S 1J0, CANADA.

**Getting Started**

**Planting Nut Seed:** Nuts are very perishable and can easily lose their germination ability if they dry out or mold in storage. It works best to plant nuts very soon after you harvest them. Plant in a cold frame or directly into your orchard. But this presents another problem since squirrels and rodents are likely to dig up the nuts and make a meal of them. The answer is to plant with some sort of cage over the seed. A good technique is to put the seeds between layers of sand in a wire-screen covered box. Or to make an individual cover that you can leave until the seedling is developed: a tin or aluminum can with its bottom cut out and its top slit and folded back enough to let in light but not enough that a critter could get through. Push a can fixed like that down on top of each seed you’ve planted. Seed nuts need time out in the cold outdoors in order to stratify and be able to germinate come spring. It doesn’t hurt them to freeze.

**NOTE:** Grafted trees will produce much sooner than seedlings. Only quality trees are grafted, so if you buy grafted trees you’re guaranteed good nuts.

**Nut Nurseries:** These are only a few of many, but all these are recommended. More entries may be at the individual nut listing.

**Burnt Ridge Orchards** offers hardy almonds, pine nuts, ginkgo nuts, monkey puzzle nut trees, hazelnuts, walnuts, chestnuts, northern pecans, and oaks that grow edible nuts! 432 Burnt Ridge Rd., Onalaska, WA 98570; 360-985-2873; fax 360-985-0882; burntridge@myhome.net; landru.myhome.net/burntridge.

**Cammberly Farm** sells seedlings of hardy pecans, sweet chestnuts, hardy almonds, heartnuts, kingnut hickories, Carpathian walnuts, sweet kernel apricots, persimmons, pawpaws, filberts, hazelnuts, etc. Catalog $2, payable to R. D. Campbell: 905-262-4927; RR 1, Niagara-on-the-Lake, Ontario L0S 1J0, CANADA.

**Exotica Rare Fruit Nursery** will send Bunya bunya, cashew, chestnut, ginkgo nut, Italian stone pine, jojoba, macadamia, and Ecuadorian black walnut plants to CA, NV, or AZ only: PO Box 160, Vista, CA 92083.

**John Gordon Nursery** offers a few grafted nut trees and many kinds of seedlings, nut seeds, and scion wood: 716-691-9371; 1385 Campbell Blvd., Amherst, NY 14228-1404; nuttreegordon@hotmail.com; geocities.com/nuttreegordon.

**Grimo Nut Tree Nursery:** John and Lisa Brittain spring-ship grafted and seedling trees—Persian walnuts, black walnuts, heartnuts, butternuts, apricots, Korean pines, hazelnuts, chestnuts, hickories, pecans, and fruits—to the U.S. or Canada: phone/fax 905-934-6887; RR 3 Lakeshore Rd., Niagara-on-the-Lake, Ontario L0S 1J0, CANADA; nuttrees@grimonut.com; www.grimo nut.com.

**Grinnell Nursery:** Sid ships custom grafted hazel, Persian walnut, and black walnut by UPS or US Postal: 517-625-7176; 14495 Morrice Rd., Perry, MI 48872-9548; grinnellnursery@tds.net.

**Lennilea Farm Nursery** sells grafted trees and seedlings: 215-845-2077; RR 1, Box 314, Alburtis, PA 18011.

**Nolin River Nut Tree Nursery** is a small family-owned outfit that offers custom grafting and 200+ varieties of budded or grafted black and Persian walnuts, butternuts, northern pecans, hicanos, hickories, butternuts, Chinese chestnuts, heartnuts, pawpaws, and persimmons. Free catalog: 207-369-8551; 797 Port Wooden Rd., Upton, KY 42784; john.brittain@gte.net; www.nolin nursery.com.
Pacific Tree Farms offers varieties for the Southern zone.
Specially in new and rare trees: 619-422-2400; 4301 Lynwood Dr., Chula Vista, CA 91910.
Raintree Nursery: For the backyard grower, they offer
Ennis and Butler filberts, filbert hedges, trazels, filazes, beaked hazel (Corylus cornuta), Chambers and Spur­
geon black walnuts, Layeroka and Colossal chestnut, Titan almond, and the Goldenhorne tree (Chinese edi­

Nut Crop Management and Recipes

**STORAGE:** Nuts need protection from both air and heat to prevent the oil in them from becoming rancid. They keep best in the shell—best of all at 32–36°F, at 60–70 percent humidity. And use them up within a year. If you have shelled nuts, they’ll keep better whole than chopped. They’ll keep better unroasted than roasted. Shelled nuts, if stored in a tightly closed container in the refrigerator, will keep for several months, which isn’t bad if you can spare the refrigerator room. You can also freeze either shelled or unshelled nuts. They’ll keep up to 2 years there.

Dry nuts at least 2 weeks before storing. It doesn’t hurt nuts to freeze, so they can be stored outdoors. But don’t store nuts where light, heat, mice, or moisture can get at them.

**CRACKING:** To crack 1 nut or a bushel of nuts, the basic procedure is the same: Lay the nut on a hard surface and hit it with a hammer. Hard shells will be easier to crack and nut meats less fragile and liable to break if you first soak the nuts in warm water. After the soaked nuts are cracked, spread out the nut meats to dry for several hours before you put them away. For very hard-shelled nuts, try freezing them first, then crack them while they’re still frozen.

But gadget-makers have invented wonderful aids to this chore, not only the old-time hand-held nutcracker, but also modern techno marvels like the famed Potter Walnut Crackers from 918-224-0567; PO Box 930, Sapulpa, OK 74067. They crack both hard- and thin-shelled nuts (hicko­ries, hazels, pecans, almonds, butternuts, Brazils). Burnt Ridge Nursery offers the Asuite Nutcracker, a hand-cranked tool that cracks more than one nut at a time and is easily adjusted for English walnuts, hazelnuts, pecans, and almonds. The large 10-in. hopper will crack nuts nearly as fast as the hopper is filled, as much as 50 lb. of hazelnuts (90 percent whole) in about 1 hour. Their Top Cracker will shell all your pecans, walnuts, almonds, filberts, even Brazil nuts. Or get the Amish-made “Our Best” nutcracker from Lehman’s (it can crack black walnuts): 888-438-5346; www.Leihmans.com.

**ROASTING:** Bob Keene, Amboy WA, who is also the food columnist “Cousin Grace,” sent the following note and recipe: “Carla, the so-called ‘roasted’ nuts people buy are not roasted, but deep fat (French) fried. That can be avoided.”

**QUICK STOVETOP NUT “ROASTING”** Roast the nuts in a heavy frying pan or Dutch oven on top of your stove. It will take 10–15 minutes on very moderate heat. Add 1 t. salad oil per cup nut meats. Mix the oil in well before start­ing. It will help you get even browning. After the nuts are done, sprinkle salt over them if you want. If oiled, cool on ab­sorbent paper.

**COUSIN GRACE’S (BOB KEENE’S) TRAIL MIX BALLS** “Use about 1 part any dried fruit to 3 parts nuts. The fruit—dates, raisins, figs, berries—acts as a binder. The nut portion can be any kind of nuts: pine nuts, sunflower, walnuts, pecans, filberts, peanuts, pumpkin seeds, etc. First chop the fruit and nuts in a food processor or meat grinder. If you don’t, the stuff won’t stick in balls. After the mixture is run through the food processor, pick some up in a teaspoon and make it into a ball. To prevent the balls from sticking to each other, roll them in sunflower seed meal, rice flour, or whatever. They can be stored and carried in Ziploc bags or empty margarine tubs.”

Thank you, Cousin Grace, for your great recipes, and say “hi” to your wife from me.

**RUTH’S NUT CANDY** “Grind 2 c. any kind of dried fruit. Combine with ¾ c. any kind of nut butter. Optional: add the juice and grated peel of 1 lemon. Mix thoroughly, then form into any sort of shape. Or use cookie cutters. Roll in coconut if you like coconut.”

**BASIC NUT/SEED BUTTER** Blend a cupful of nuts or seeds to produce your butter. If they seem lacking in spreadability, add a little more oil. Sesame seed butter is called “tahini” and is good spread thin on a cracker.

**MIXED NUT BUTTER** Prepare ¼ lb. almonds, ½ lb. pecans, ½ lb. filberts (hazelnuts), and ½ lb. roasted peanuts. Put them all through a grinder and then mix well. Pack in a glass or some other straight-sided container and chill. When wanted for use, dip the container in hot water and the contents will more easily slip out. Cut into slices. Good for vegetarians.

Through the Nut Alphabet

**ACORN:** The little acorn grows on the mighty oak (you knew that). Oaks can grow to be very old, over 200 years! They can reach a very large trunk diameter and a crown spread of up to 50 feet. (Crown spread is measured from branch tip to opposite branch tip.) A wonderful book called *Acorns and Eat 'Em*, by Suellen Ocean, provides a field guide to 18 kinds of oak trees and their acorns, plus recipes. Yes, it tells how to harvest, prepare, and cook acorns! Send $15 for the book ($15.91 CA residents), or $19.95 for her video version ($21.25 CA residents) to Ocean-Hose, PO Box 115, Grass Valley, CA 95945.

**Oak Varieties.** The 2 main categories of the some 300 varieties of oak are the black (and red) oaks and the white oaks. Most unprocessed acorns aren't immediately edible for people—too bitter from the tannin content. (But tannin is used in tanning hides into leather.) Black oak acorns contain so much tannin, they're scarcely worth the effort to make edible. But acorns from the white oaks (they have rounded lobes on the ends of the leaves and no bristles) contain less tannin and what is there can be gotten out by leaching. White oak varieties that are good for acorn-growing are the "white oak," "swamp oak," "but oak," and "chestnut oak." The bur oak (*Quercus macrocarpa*) grows wild in eastern North America. The Oregon or Garry white oak (Q. garryana) is another suitable choice. Burnt Ridge Nursery sells 6 different oak varieties, including the cork oak and ones with good acorns for human or stock feed.

**Oak Timber.** Among the oaks suitable for the Northwest climate are the cork oak (Q. suber), which has an edible acorn plus a bark that is used for cork. In old-time Europe these trees were grown on cork estates in Portugal. Oak timber is valuable. White oak is also considered the world's best wood for holding liquids and is ideal for making barrels because of the reddish-brown "gum" that blocks the wood pores. Varieties vary considerably in growing speed, time to bearing, and acorn production.

**Climate.** Oaks can grow from Alabama northeast to New England, north to Minnesota, and east to Texas. The Ohio and Missouri areas are fine for oaks.

**Harvest.** Young oaks typically produce a couple bushels of acorns per tree. Old ones can produce prodigious harvests of acorns, even as much as a ton per mature tree, but more likely about a third of that. Oaks vary hugely in the amount of acorns they will produce from variety to variety, and from year to year. Some oak trees have alternate-year bearing cycles; some give a light harvest one year and then a heavy crop on the third. The ilex (holly) oak bears as much as 900 lb. of acorns on alternate years. Some bear significantly only every third or fourth year but give 500–600 lb. of acorns at that time. The emory oak, however, is said to bear almost every year, at least 4 bushels. One of the reasons for delayed bearing may be acorn crops that are lost to early frosts. But the tree tends to make up for lost time when it does get a crop past the frost risk. The larger the tree, the larger the acorn crop it can bear. Grafted oak trees generally yield at least double the acorn harvest of wild ones.

**Acorns for Livestock Feed.** Acorns provide food for both humans and their livestock (especially pigs, which will feed themselves off the acorns that drop and get fat on them)—a tradition that goes back to antiquity. Acorns are the best keepers of any of the nuts. They'll lie under the tree for a long time without rotting, which makes them perfect for a forage crop. Pigs will roam happily under the oaks, eating nuts as needed. Chickens love acorns that have been broken up so they can get at the nutmeats.

**ACORN MEAL.** Fortunately, tannin is very soluble in hot water. So, peel the acorns. Grind them up. Sook the "flour" in very hot water. The water will turn brown, because of the tannin coming out. Throw away the water and repeat 4 times. Another way to do this is to line a colander with a straining cloth, put the ground acorns in, and gradually pour a gallon of water, as near boiling hot as you can manage, through. There will still be some dark chocolatey color to the paste, but after exposure to a gallon of hot water, you can be confident that enough tannin has been removed to render the acorn meal edible. Spread the acorn paste on a baking sheet and bake at a low temperature until thoroughly dry. If it has caked, grind again, and you have your acorn flour. You can substitute acorn meal for cornmeal in any recipe, or use part acorn meal and part cornmeal, or 1/2 acorn meal and 1/2 oatmeal.

**ALMONDS:** Almond (Prunus amygdalus or Prunus dulcis dulcis) trees are related to peach and plum trees and are similar in habits. They grow 15–30 feet high with an equal spread of branches. Some varieties are bushy, others more treelike. Almonds start to bear nuts after 3 years of growth, but they don't achieve full-scale production until they're about 12 years old. But once your almond is mature and bearing nuts, it will yield for another 50 years, if kindly cared for.

**Climate.** The sweet almond does best with a long, warm growing season (zones 7–9), plus low humidity. Most almond orchards are on the West Coast, principally in California. Almond's tendency to bloom a month earlier than peaches means that although the trees can survive in northern areas it's hard to get a nut crop during any year you have an early frost.

**Varieties.** Almond extract is made from the bitter almond tree, which grows in Europe and whose nuts contain enough prussic acid that you couldn't eat more than a few. Bitter almonds are hardier than sweets and can be raised anywhere that peaches can. There are dwarf almonds that can be grown in containers. There have to be 2 different cultivars, but the almond is pollinated by bees rather than wind so the pair doesn't have to be planted really close together. New Halls have received a lot of publicity, but Tucker Hill wrote me, "I've spoken to a number of people who were disappointed with this almond."

**Planting.** Soak dried seeds a day, then stratify at 40°F or simply plant the seed in the fall where you want it to grow. Choose well-drained soil. Protect seed from being dug up by squirrels by placing a "cage" over it until it is well-started. Or bud graft on a seedling rootstock. Good stocks are bitter almond, peach, peach–almond hybrid, plum (if resistant to oak fungus), or any other almonds. Nemaguard and (peach) Lovell are good for waterlogged or irrigated areas. Good scions are Bartre, Nonpareil, and Mission. Plant the smaller (15-foot) varieties 20 feet apart. Avoid unnecessary pruning of the young tree because that will delay nut production. Train like a peach.

**Harvesting.** Your almonds will be ready for harvest in August or September. *How to Grow Vegetables and Fruits by the Organic Method*, edited by the Rodale staff, available from
sugar and 2 stiffly beaten egg whites. Work it all together, pound them to a paste in a mortar, or put several times

OLD-TIME MACAROONS
Blanch ½ lb. almonds and pound them to a paste in a mortar, or put several times through a grinder set on “fine,” or blend. Add ½ lb. powdered sugar and 2 stiffly beaten egg whites. Work it all together, then form balls about the size of a whole nutmeg. Bake at 250°F until light brown.

MACAROONS WITH ALMOND PASTE
Add gradually to ½ lb. of almond paste, ¼ c. sugar and 3 beaten egg whites. Mix well and add ¼ c. powdered sugar and 2 T. flour. Put teaspoonfuls on a paper on your cookie sheet. Flatten the shapes a little. Bake at 250°-300°F for about 30 minutes.

MARZIPAN
In the old days marzipan was also known as “toy candy,” a traditional holiday treat. To make it, mix 1 c. almond paste, 1 c. powdered sugar, and ½ t. orange or vanilla extract, or rose water (the traditional flavoring). Knead it a long time—20 minutes maybe—and then set it on a rack to dry. After drying, it can be shaped into tiny replicas of fruits, or whatever takes the cook’s fancy.

Coloring: After drying your molded shapes at least overnight, paint them with food-coloring using a small paint-brush. Or dip them into the color Easter-egg style. Then give them time to dry. You can also give them accessories such as cloves for stems and leaves made of bits of angelica.

Glazing the Figures: Leave them covered with heavy sugar syrup 8 hours. Make the syrup by cooking 5 lb. sugar and 2/2 c. water to the soft-ball stage — 234–240°F. Remove syrup from heat and let it cool. Add marzipan in a single layer. It is important throughout to avoid disturbing the syrup as much as possible. Then drain your candies and let them dry again.

BEECHNUTS: Beech trees can live very long, well over a century, and grow very large. Although the Beech was originally wild, domestic varieties have been developed that yield larger-sized nuts than the wild or seedling trees. Brown beechnuts are good to eat. The American beech grows to 50–75 feet high. Beech trees are very hardy, suitable for zones 4–9, and only rarely lose a crop due to spring frost. They have good disease resistance and no insect problems. They are self-fertile. Plant them 80 feet apart. The tree produces a crop of triangular nuts covered with a burr.

BRAZIL NUTS: This tropical nut grows wild in the Amazon forests of Brazil. It can’t be grown unless you have virtually tropical conditions, including heat, lots of rain, and fertile soil. The most southern tip of Florida might be suitable. Mature Brazil nut trees are big and beautiful. Their nuts grow inside hard wooden outer husks about 4 inches across, 18–24 nuts to the husk. They’re delicious eating—rich in fat, protein, a little carbohydrate, and a lot of calcium!

CASHWEDS: The cashew, Anacardium occidentale, is a little evergreen tree that comes from the West Indies and can’t grow outside the tropical zone. Trees bear only after 4 or 5 years. You can plant seeds, which grow reasonably soon, or graft.

The fruit, called “cashew apples,” is ready to harvest in early summer. Sticking out of the base of each cashew apple is the cashew nut inside an outer shell. But the nut is protected by a substance similar to poison ivy, released to do its damage if the shell is broken by some would-be cashew eater. The solution is to roast the nuts before shelling because that disarms them. The cashew apple has no such problem. You can eat it raw or cooked or juiced or anyway you would a regular apple.

CHESTNUTS: The chestnut (Castanea) tree produces abundant flowers from which honeybees love to gather pollen and nectar. A single tree can produce 250 lb. or more of nuts every year. Chestnuts are specialty nuts that are especially popular at Thanksgiving and Christmas time.
Varieties. There are chestnut varieties that bear early (Meiling Chinese chestnut), middle, and late. By planting some of each you can prolong your harvest season. The other big factor to consider is blight resistance.

American. The splendid American chestnut was a relatively fast-growing tree, reaching up to 60 feet tall with trunk diameters of over 3 feet in less than 60 years. And that chestnut timber was an excellent hardwood with many uses. But those native American chestnuts (*Castanea dentata*) of the eastern and southeastern United States all died as a result of the terrible air-borne blight disease that arrived from the Orient in 1904 in a shipment of plants—and still attacks any vulnerable chestnut. Before that, the American chestnut, a superior variety both for timber and nut production, grew huge and wild, making up as much as half of the natural forests in its area. There were also large commercial chestnut orchards, the chestnut being an economical and valued “tree corn.” Although new suckers continue to try to grow from the stumps of some of the old giants, they are struck down by the blight after reaching 20–30 feet.

The chestnut blight, incidentally, presents a very clear example why we should always maintain genetic diversity, even at the cost of supporting some obviously less desirable varieties of a species!

Hybrids. The few American chestnuts that have survived have been propagated and hybridized with European (the Spanish) or Asian (the Chinese) chestnuts. Burnt Ridge offers many chestnut varieties. Chestnut Hill Tree Farm sells bare-root Dunstan seedling chestnuts through the U.S., January to April. Dunstan is a blight-resistant American-Chinese hybrid. (Actually, not one person has ever died of the blight, and this is the most widely planted chestnut in the U.S. today.) They have large nuts, timber tree form. They have been grown successfully from Maine to Florida, west to Illinois and Texas, and on the Pacific Coast from Washington to California: 386-462-2820; 15015 NW 94th Ave., Alachua, FL 32615-6709; www.chestnuthillnursery.com.

Chinese Chestnut. *Castanea mollissima*, the most blight-resistant and most popular chestnut variety, grows about 35 feet high and bears tasty nuts. It is hardy as a peach, rarely suffers frost damage, and lives a long time. Most nut trees prefer neutral or slightly alkaline soil, but this one favors a slightly acidic one. Its wood is very brittle. Head back long branches to avoid breakage.

Chinquapins. These are a small, native-American, Southern chestnut, which is basically resistant to the blight.

Japanese Chestnut. There are several varieties of this one (*Castanea crenata*). Mostly they grow into a large bush or small tree, but some grow into trees as tall as 30 feet. In the past, this tree hasn’t been as blight-resistant as the Chinese, but the folks at the the Connecticut Experiment Station (New Haven) have managed to create some promising new crosses of the American chestnut with the Japanese that are quite blight-resistant. Essate-Jap and Sleeping Giant. This variety is more suitable for the warmer zones, hardy only in zone 7 or south of it.

Native Northwest Chestnut. The *Castanopsis chrysophylla* species hasn’t been hit by the blight. The Northwest is now one of the best areas in which to grow chestnuts because of fertile soil and moderate climate—and because the chestnut blight has not yet found its way into the area.

Planting. Chestnuts are not self-pollinating; plant 2 or more. Open-pollinated European or European–Chinese hybrids are for dual-purpose timber plantings, blight-resistant Laye­roka seedlings for nut orchard pollinators, graftedayeroka and Skookum for nut orcharding, and others. Nanking, Kuling, and Abundance are older favorite varieties.

Fall planting is possible, but chestnut seeds (nuts) must experience at least 3 months at temperatures 40°F or below in order to germinate. They will grow best if planted lying on their sides, in humus-rich soil of pH around 5.5, protected from nut-eating predators. Or you can store your seed in a very cool place. With luck chestnuts retain germination ability for as long as 3 years. Or you can graft or bud. Serious chestnut growers almost all use grafted trees.

Pruning. Chestnut wood is brittle, so prune early for a strong central leader, horizontal crotches, and balanced branch arrangement. Prune only when leaves and nuts have fallen and the tree is dormant. Chestnut pollen is carried by wind or insects.

Harvesting. On the tree, the chestnuts grow inside of burrs. When ready in the fall, the burrs split and spill out the nuts inside onto the ground. You must pick them up before they have a chance to get moldy, wormy, or eaten by squirrels or 4-legged furries.

Storing. If you put chestnuts in water, bad ones will float. When you refrigerate them, give them air by packing them in loosely covered containers or in plastic bags that have holes in them. Unshelled chestnuts will stay fresh for several months if refrigerated, and for much longer in the freezer.

Cooking. Human food for some 6,000 years, chestnuts are an unusual nut because they are mostly starchy with only a little fat, so you can do vegetable kinds of things with them. Prepare like a vegetable main dish; grind into a flour; prepare in a soup or sauce; add them to pasta, pastry, or desserts; and, of course, roast them over an open fire.

Shelling by Roasting. Roast in an oven 15–20 minutes at 375°F. Then peel.

Shelling by Boiling. With a sharp knife, cut a crisscross gash on the flat side of the shell of each chestnut. Simmer until they are quite soft, about 15 minutes. Remove nuts from water, shell, and remove brown skins with a sharp knife. Then go ahead with any of the following recipes. It helps to lift the nuts out one at a time and peel off both shell and inner skin while the nut is still damp.
Freezing. Shelled, blanched chestnuts should be frozen if you won't be using them within a few days. Just pack any chestnut puree recipe in containers that can be closed tightly. Use in cooking without thawing ahead of time.

CHESTNUT-MEAT-STOCK PUREE. Cook peeled chestnuts in meat stock, or in a half-and-half mixture of milk and water until they're tender. Puree nuts in a blender or food mill. Make a soup by mixing some of the puree with the stock.

CHESTNUT-SQUASH PUREE. Mix chestnut puree with squash or pumpkin puree for a special side dish. When freezing this puree, prevent separation by mixing in either 1 T. butter or 1 T. honey to each cup of puree before freezing.

PLAIN CHESTNUT PUREE. Boil peeled chestnuts in lightly salted water until tender. Then mash and add a little butter, salt, and pepper.

CHESTNUT POULTRY STUFFING. To the puree, add bread crumbs, beaten eggs, and a little of the juice in which the chestnuts were cooked.

CHESTNUTS AND SPROUTS. Sliced chestnuts are good with Brussels sprouts.

PLAIN CHESTNUT CHICKEN SOUP. Chestnuts go well with chicken soup. Cook 1 c. peeled chestnuts in 2 c. chicken soup until tender. Add about 6 c. more chicken soup. Season with salt and pepper and serve.

FANCY CHESTNUT CHICKEN SOUP. Heat ¼ c. butter in pan. Fry a half dozen chopped green onions or 1 small chopped globe onion until golden. Add 1 lb. fresh, simmered, peeled chestnuts. Fry 1 minute, stirring constantly. Add ½ c. chopped celery or celeriac and 2 c. chicken stock, and cook 30 minutes or until chestnuts are quite tender. Strain solids out of the broth and puree them. Then stir back into the broth. Reheat just to a boil. Add salt and pepper to taste, a pinch of nutmeg, and 1 c. light cream (or half-and-half). Do not boil.

DIFFERENT CHESTNUT SOUP. Puree 2 lb. fresh chestnuts, or use 1 lb. unsweetened chestnut puree. Heat puree in 1 qt. vegetable stock. Add 1 c. finely grated carrot (or salsify) and cook on low heat about a half hour. Melt 2 T. butter in a separate pan. Add 2 T. flour and cook, stirring constantly, until it begins to darken. Add the hot chestnut soup in slowly, stirring to keep it blending. Add ¾ c. red wine, ¼ t. nutmeg, ¼ t. cayenne, and salt and pepper to taste. Cook 10 minutes more over low heat (stirring often!). Sprinkle a little paprika over each bowl you serve.

CHINQUAPIN: See “Chestnuts.”

COCONUT: There are many different varieties of palms, all tropical species. The beautiful coconut palm (Cocos nucifera) grows in both the East and West Indies, the tropical Americas, the South Pacific, Southern California, and Florida. They can grow as high as 100 feet tall. It has no fruits maturing all year round. Coconuts are salt tolerant. Ocean sprays, wind, flooding, or even an occasional covering with salt water doesn't hurt them. Palms can also be tapped for their sweet sap. But they need lots of humidity, a frost-free climate, 40–60 inches of rain fairly evenly distributed through the year, and a minimum average temp of 72°F.

Planting. A coconut husk high on the beach may have dropped from a tree into the ocean and floated for thousands of miles before washing ashore. Under natural conditions, eventually it will sprout and grow. To plant the seed yourself, place an unopened coconut into a partially shaded nursery bed. Leave the top half of the shell outside the dirt. Keep it moist. If you plant while the nut is still a bit soft it will germinate in only a few weeks. Once the nutshell gets fully hardened, it may take as long as 4 years to germinate.

Harvesting. Dwarf trees bear in 3–5 years, standards in 5–10 years. Once the tree starts, coconuts will continually ripen year round, more every year—from 50, when it's young, increasing to maybe 200 when the tree is fully mature at 15–20 years. The fruit is covered with an outer husk that is made of tough fibers that are very resistant to saltwater. It changes from yellow or green (depends on variety) to brown as it ripens. Those husks are used to make fishing nets, doormats, rope, and brushes. The nutmeat is inside a tough shell, which itself is inside the husk. The shell can be used as a bowl. You can harvest using a knife fastened to the end of a long pole.

Opening a Coconut. Pound something sharp through one of the 3 “eyes.” The shell is thinnest there. Then drain the coconut milk into a cup. Next, whack the shell with a mighty hammer blow and it will crack wide open so you can get at the nutmeat. It can be eaten fresh or dried.

MAKING COCONUT MILK. The store product called “coconut milk” or “mix” for making alcoholic drinks is not the real thing and can't be substituted for genuine coconut milk in tropical cuisine. The clear liquid at the center of the coconut is sometimes called “coconut milk,” but usually coconut milk for cooking is produced by the following method: Cut fresh coconut meat up into cubes about 1 inch on the side. Measure out an equal amount of hot water. Place water and coconut in your blender and blend at a high speed for a couple minutes. Let rest 30 minutes. Set a strainer over a bowl and pour the puree into it. Squeeze out as much “milk” as you can by pressing on the pulp. Giving the coconut milk an extra straining through an even finer mesh makes it nicer. Coconut milk will keep fresh only a few days in the refrigerator. If you need to store it, freeze it. Real coconut milk can be used to make sauces, soups, desserts, and curries.

SHREDDING COCONUT. Open a hole in your coconut, and pour out the milk. Drink the milk or save it for cooking. Grate the coconut meat or shred it with a vegetable shredder.

TOASTING SHREDDED COCONUT. Put the shredded coconut in a flat pan and put the pan in the oven at about 200–300°F. Stir occasionally until it is dried. You can also sun-dry coconut. All you have to do is cut the meat into thin slices, spread it on your trays, and put it in the sun to dry. Dried coconut is called “copra.” Store copra in airtight cans or jars. Add copra to puddings, eat it as a sweet, or use it in any recipe in place of nuts.

COCONUT MILK MADE FROM DRIED COCONUT. Combine 1 c. natural (unsweetened) dried coconut with 1½ c. hot water. Let rest 5 minutes. Puree and strain.

COCONUT CREPES WITH POLPANI FILLING. Sift together ¼-lb. sorghum flour and ¼-lb. wheat flour 3 times.
You can grow filberts in colder climates if you get the late-bridged, and improved plant, one of the nuts with the disease resistance, the best chance of escaping frost damage, and the best general hardiness. There are many other species.

Filberts: The filbert is a long-domesticated, much-hybridized, and improved plant, one of the nuts with the distinction of regularly appearing in holiday nut mixes. This nut is popular as a yard-grown tree, being easy to grow, hardy (zones 3–6), and naturally on the small side. In Washington and Oregon filberts are grown commercially. You can grow filberts in colder climates if you get the late-blooming kind. Filberts occasionally lose a crop to frost (again, hazelnuts are hardier).

Propagating. You can reproduce filberts easily by layering. To layer, bend a low filbert branch clear to the ground, cover the middle portion with dirt, and put something heavy on top to hold it down like that. Soon that covered (layered) section will have taken root on its own. Eventually you can cut it loose from the parent tree, and later yet you can transplant the newly rooted to wherever you want it. The filbert doesn't have the long taproot of the walnut family, so it's easier to transplant. Grafting and budding are another option. Good stocks: Turkish tree hazel (C. colurna); and C. americana and C. cornuta, both disease-resistant Americans. Good scions: Barcelona and Nonpareil.

Place flour in a bowl. Add salt to taste, and the yolks of 6 eggs. Add 3 1/2 c. thick coconut milk. Mix with a wooden spoon. Gradually add 3 1/2 c. more of thick coconut milk. Beat the whites of the 6 eggs to a very stiff foam and fold them into the batter. Set the crepes batter aside and prepare polpani. (You can substitute any crepe filling for the polpani.)

To prepare polpani (brown sugar and coconut filling): Place 4 oz. unrefined brown sugar in a pan. (The original recipe calls for 4 oz. “jaggery,” which is an unrefined brown sugar made from palm sap.) Add 2 T. water and a 1/2-inch piece of cinnamon stick. Stir and cook over heat until syrup thickens. Add 4 oz. fresh coconut scrapings and a pinch of salt. Keep on low heat a few more minutes, until mixture thickens.

Now put your pancake pan on the heat and melt a little butter, margarine, or coconut oil in it. Pour enough batter into the pan to make a pancake about 5 inches wide and very thin. When it is cooked on one side, turn it over. When both sides are done, slip the crepe onto a plate, put a spoonful of the polpani in the middle of it, and then roll it up.

**COCONUT BREAD** Combine 2 c. shredded coconut, 1 c. mashed other fruit, and 5 eggs. Mix well. Sift together 2 t. salt, 2 t. baking soda, and 4 c. any flour (doesn't have to be a wheat flour!). Add 1 c. brown sugar and mix all ingredients well. Let rest 20 minutes. Stir once. Pour into a greased pan. Bake at 350°F. Cool, then serve.

**COCONUT OIL** When dried coconut is pressed, it yields coconut oil.

Green Coconut. You don't have to wait until a coconut is fully ripe to eat it, although that is the proper stage at which to harvest if you want to press it from it. The immature coconut flesh is soft: “green coconut.” Eat it with a spoon. It's delicious, nourishing food, traditionally given to infants, the elderly, or ill people.

**Filbert Family:** Hazelnuts and filberts aren't the same thing, but they are related. The hazelnut (Corylus americana) is a native American filbert. It's a small bush that can grow up to 8 feet tall. The filbert (Corylus avellana) is a large bush that can be pruned to take the shape of a small tree. Filberts grow up to 15 feet tall. Both filberts and hazelnuts are relatively quick growing and produce nuts early within other varieties, the females bloom first. You're fortunate if you can get them both to bloom at once, which is what you need for fertile seeds.

Growing from Seed. Growing filberts from seed can be difficult if you're doing it on purpose. On the other hand, volunteers from careless birds or forgetful squirrels may grow generously. To grow, seeds must have been successfully pollinated, then chilled at 40°F or below for at least 3 months. If your seed doesn't germinate the first spring, don't despair, because sometimes it will after 1 or 2 years or even longer. If you plant numerous seeds in pots, flats, or a nursery bed in your garden, you can hope for better success. In their permanent location, plant filberts 20–25 feet apart.

**Pollinating.** Barcelona is a good pollinator for Daviana. Filbert trees have unusual blooming patterns. The trees do not have a natural dormant period. They can be loosely classified into early bloomers, mid-bloomers, and late bloomers. Early bloomers start about November and continue into January and February. Mid-bloomers bloom mostly in the winter months. Late bloomers start later and continue until March. To make it even more murky, sexes may bloom at different times. The males of some varieties bloom first; within other varieties, the females bloom first. You're fortunate if you can get them both to bloom at once, which is what you need for fertile seeds.

**Pruning.** Easterners usually let filberts grow as a large bush (limited to 5 or 6 stems so the center doesn't get too dense), but on the West Coast, they are often pruned to a single main stem to make them look like small trees. Prune mature plants in a way that lets more light into the center of the tree. Prune only during winter.

**Cooking with Filberts.** Filberts may be toasted, ground, and so forth. For baking they are usually left unblanched, for the pinkish skin adds much to their flavor and food value.

**Removing the Skins.** Spread the nuts on a cookie sheet or in a shallow baking pan. Bake at 300°F for 15 minutes, stirring occasionally. After they have cooled enough to handle, you can rub the skins off with your fingers. If you plan to
chop filberts, toast them after chopping. Store toasted nuts in an airtight container. Filberts make a great nut flour.

Harvesting. Filberts that are pollinated in January or February will grow in spring and drop in September and early October. The female flower has already been growing a year and a half when the filbert nut, which has been attached to it almost 8 months, finally drops. Pick up the nuts as soon as possible to prevent mold and to reduce loss to birds and squirrels. Give them the water test—floaters are not good. Dry them by spreading them out in a dry room and stirring them occasionally. Store in the shells in a place where mice and rats won’t be tempted.

Hazelnuts: These trees differ from filberts in that their smaller size allows you to plant them only 10 feet apart. The nutmeats are good-tasting but tend to be smaller than those of the filbert. Winkler is a good variety. Hazelnuts make a nice raw nut butter. You can mix it with vegetable or fruit juices to make a salad dressing.

Heartnuts: See “Walnuts.”

Hickories: Hickories (Carya) grow wild in the central and eastern United States. They naturally grow into straight, very tall trees (maybe 50 feet) and are sold for their unusually strong wood, used to make tool handles. Hickory wood is also a prized firewood, and the bark is excellent for smoking meat. It takes a hickory tree an average 5 years to start bearing nuts. When mature, they’ll produce 4 or 5 bushels per year. They can be stored in the shell for months in a cool dry place.

Hickory Varieties. Hickories include pecans, bitternuts, shagbark, water hickory, mockernut, shellbark, and pignuts. There are still other varieties that are natural hybrids, and more that have been developed by plant breeders for the big commercial pecan market. The value of the nuts depends on the variety.

Bitternut. The bitternut is practically inedible. Bitternut is the hickory that can grow farthest north, even in southern Canada, though the shagbark, shellbark, and mockernut hickories are also very hardy.

Shellbark and Shagbark. The pecan is the prime culinary and market variety; the shellbark and shagbark compete for second-best. The shellbark bears a large, white, 4-cornered nut with a sweet kernel. The shellbark hickory grows wild from Tennessee north to New York and is a good nut tree, straight, very tall trees (maybe 50 feet) and are sold for their unusually strong wood, used to make tool handles. Hickory wood is also a prized firewood, and the bark is excellent for smoking meat. It takes a hickory tree an average 5 years to start bearing nuts. When mature, they’ll produce 4 or 5 bushels per year. They can be stored in the shell for months in a cool dry place.

Shellbark and Shagbark.

Hickories include pecans, bitternuts, shagbark, water hickory, mockernut, shellbark, and pignuts. There are still other varieties that are natural hybrids, and more that have been developed by plant breeders for the big commercial pecan market. The value of the nuts depends on the variety.

The shellbark hickory grows wild from Tennessee north to New York and is a good nut tree, though the shagbark, shellbark, and mockernut hickories are also very hardy.

Shellbark and Shagbark.

Pecans. Pecans (Carya illinoinensis) are a hickory variety—a good tree that is easy to grow, does fine in yards, and bears a nut that is easy to shell. Some small varieties have been developed that are more suitable for a small yard. A paper-shell pecan tree can give you 100 lb. of pecans a year. One way to choose your varieties is between southern early-bearers (Candy, Elliott, Shoshoni, Success, Western, etc.) and southern late-bearers (Curtis, Mahan, Schley). Read ATTRA’s “Sustainable Pecan Production” at www.attra.org/attra-pub/pecan.html.

Climate for Pecans. Big pecan crops are possible all over the southern and southwestern United States and in California. The southern pecan is the least hardy and requires a long growing season, so commercially they are usually grown only from Georgia on south. However, northern pecans are grown in Kansas and Nebraska, as well as Illinois, Indiana, Ohio, and Pennsylvania. The variety you buy needs to be exactly chosen for your climate zone. Tucker Hill warned me to beware of Southern pecan propaganda. “Northern pecans are smaller but higher in flavor. Both Kansas and Nebraska are producing outstanding pecans. We do quite well here in Pennsylvania.”

Planting Pecans. You can plant seeds, grafted, or bud. But seeds can’t be depended on to breed true. In the South, plant seeds in the ground any time following the nut drop and before the next spring, as long as the contents of the nut haven’t dried out. Northern varieties need to be chilled in the ground or in your storage area at just above freezing for about 2½ months in order to germinate. To bud pecans, large varieties should be selected for stock. Seedlings take years to reveal what you’ve got—8 or more. Grafted trees usually take about half as long. Plant orchard pecans 30 per acre. Grow 2 different varieties near each other in order to have pollination.

Harvesting. If you have trouble getting your nuts off the tree you can knock them from the branches with a pole. In the shell they will keep well in the refrigerator.

Vegan Pecan Burgers. From Ruth of Bonaire: “Combine 1 c. ground unroasted pecans, 1 c. wheat germ, 1 c. bran flakes, 1 c. grated onion, ½ c. grated carrot, 1 T. tamari, and water enough to moisten, if needed. Shape the mix into patties. Fry on a nonstick or potato-rubbed skillet. Serve on buns together with your favorite toppings.”

Pecan Macaroons. Beat 1 egg white until stiff. Then gradually beat in ½ c. pecan nut meats (chopped fine). Drop mixture by teaspoonfuls onto a baking sheet covered with buttered paper. Make smooth rounds of your drops. Sift powdered sugar over the top. Bake at about 350°F.

Pralines. Combine 1½ c. powdered sugar, 1 c. maple syrup, and ½ c. cream. Boil to the soft-ball stage. Remove from heat, and beat until creamy. Add 2 c. chopped pecans (or any other nuts). Pour into a buttered pan and cut into squares.

Planting Hickories. Plant a nut, or a seedling, or grafted/named variety. But this tree has a long, strong, early-developing taproot, so don’t consider transplanting unless it’s a very, very small tree and then plant carefully and put that small tree where you’ll want to keep it. And if the taproot is cut or bent while transplanting, prune it just above the injured part.

Pruning. Prune after the nuts have fallen, in early fall. Take off a few lower limbs each year while the tree is young until you achieve a 6–8-foot bottom trunk. After that, mature trees don’t usually need any pruning.

Macadamia. This nut tree is a good-looking evergreen that’s native to Australia where it’s known as the “Queensland nut.” Later grown also in Hawaii, they are now getting
started in California and Florida, too. In Australia where the soil is fertile and the moisture abundant enough, they can get 40–50 feet tall.

**Planting.** Macadamias need to root in deep soil to keep themselves from being blown over, and they seem to do best in an acidic soil. Stratify the seeds during your coldest season; then plant them in individual pots in a greenhouse-type situation. They are slow to germinate. When you transplant be careful not to disturb the root mass. They can be grafted to better cultivars. Warm climates only.

**Harvesting.** For some reason, only a few of the hundreds of tiny macadamia blossoms produce nuts, but there are so many flowers to start with that your crop can still be generous. The nuts mature inside a husk and require more than half a year's time. The husk ruptures itself when the nuts are mature, allowing them to fall to the ground. During the harvest season (about a month long), go out at least twice a week and gather up all the nuts off the ground. Then dry them thoroughly.

**Using Macadamias.** You need a special tool (such as vise-grip pliers) to crack the shells because they are so hard. Before you use the nutcracker, spread the nuts on a baking sheet and roast at 200°F for 1 hour. Cool slightly; then shell. Store shelled nuts in the refrigerator in a covered container.

**MACADAMIA SALAD DRESSING** Ruth of Bonaire combines 1 c. of apple/celery juice or carrot juice with 3 oz. macadamia butter made from unroasted nuts. Or, she suggests using orange juice for a tropical flavor.

**MACADAMIA WALDORF** Also from Ruth: "Dice 6 tart apples. Pour the juice of 2 oranges and 1 lemon over. Chop 4 stalks celery. Drain the juice off the apples and blend juice with 3 oz. macadamia butter. Mix dressing by hand with apples and celery. Serve in lettuce-lined bowls."

**PEANUTS:** These are a variety of the legume, pea family (see Chapter 4).

**PECANS:** See "Hickories."

**PINE NUTS:** Pine nuts are also called "piñon nuts" or "pignoli." The evergreen trees (Pinus) that bear them are easy to grow and hardy across a wide range (zones 3–10), but all pines are harmed by smog so they don’t belong in the city. Piñons can thrive, however, on dry, rocky hillsides in desert climates. Pine nut trees range in appearance from tiny macadamia blossoms produce nuts, but there are so many flowers to start with that your crop can still be generous. The nuts mature inside a husk and require more than half a year's time. The husk ruptures itself when the nuts are mature, allowing them to fall to the ground. During the harvest season (about a month long), go out at least twice a week and gather up all the nuts off the ground. Then dry them thoroughly.

**Planting.** You can buy started pines from nurseries, collect them from the woods, or plant seed. Plant in well-drained soil (moist is okay). Don't fertilize. This is naturally a desert plant, and once the tree gets going, it doesn't need much watering. It doesn't need pruning either, unless there is dead wood needing to come off or it's growing somewhere that’s definitely forbidden.

**Eating.** Pine nuts are hard to crack open. Once you do get the nuts out you have top-notch food. Store them in something airtight, frozen if you want to hold them more than a month. To use: roast, salt, and eat out of hand. Or add to any rice, stuffed cabbage, Italian, or pesto recipe.

**PISTACHIO:** This deciduous nut tree (Pistacia vera) can be grown as a single tree or in a group—several make a great hedge because of the tree's tendency to grow densely. But pistachios thrive only within rather narrow climate limitations. They need some winter chilling, about 30 days of cold, but are likely to die if the temp gets below 10°F. They need a hot summer, 100 days of that. They need dry air; high humidity can be a problem. In general, you could try pistachios in zones 7–9, especially if you live where olives grow. California's Sacramento Valley is just right. In southern Turkey, ideal conditions are also present; there, pistachio trees grow wild. Within its climate zone, the pistachio is hardy and able to thrive despite thin soils; they can root even into rock crevices.
Pollination. Pistachios come female or male. You must have both female and male trees in order to have any nuts, although if you absolutely have room for only 1 tree, a length of male branch can be grafted right onto a female tree and will accomplish the job that way! The females grow to be 20–30 feet high, males even higher.

Planting. There are 2 female varieties available: Red Aleppo and Kerman. A male pistachio has got to be Peters. Few nurseries carry them, and then only in containers rather than bare root. The male and female must be planted within 50 yards of each other for pollination to be certain. Plan on planting a few: you want both sexes, and individual plants produce nuts only every other year, so to get annual production you need several plants.

Growing. They grow well from seed, or by bud-grafting, so long as they have the right climate, full sun, well-drained alkaline soil, some pruning, some manure fertilizing, and organic mulching. Once your pistachio pair is well-started it will be quite resistant to water shortages. However, if you give the trees more water, they will bear more nuts.

Pruning. Pistachios crave to be bushes. If you want trees, train to a central leader with a scaffold of 4–5 lateral branches starting 4–5 feet above ground. An unpruned pistachio can grow really dense.

Harvesting. Your pistachio tree won’t be mature enough to bear nuts until it’s about 10 years old, and it will be 15 years before it’s going well. Once bearing, in the fall the fruit will be apparent as heavy bunches of yellow or red nuts hanging prettily from the ends of branches. The color change of the shells to those pretty, bright shades signals that the nuts are getting ripe. When the nuts come away easily when picked and when the shell separates easily from the inside when squeezed, it’s time to pick the nuts from your tree. If you don’t get right at it, squirrels may do it instead. Expect 10–20 lb. of harvest from a newly producing tree. As a pistachio tree gets older, it steadily increases nut production.

Storing and Using. After picking the nuts, remove their hulls right away, for nuts in a pile in the hull tend to start spoiling almost within hours. Dry the unhulled nuts spread out in a single layer in the sun for a week. In the shell they will keep in a cool place for many months. They’re hard to work to shell. If you keep running into empty shells, that means your summer was too chilly for this plant, or else the pollen wasn’t transported successfully. After shelling, the nuts and have to prune the trees in such a way that rodents from chewing on their bark.

Grafting. Grafting any Juglans is risky because some crosses of black walnuts (and butternuts) get graft failure after 12–15 years. That’s a terribly long time to wait only to learn it didn’t succeed. Growing from seed is satisfactory for timber production, but a combination of growing from seed followed by grafting is best for nut production. The grafted tree also produces timber. If you are planting walnuts, check on the sex life of your variety. Some are self-fertile, but some need a partner. It matters, because it’s quite likely you don’t have space for two of them!

Pruning. Walnut wood is so strong that there is no need to worry about weak crotches. Basal-prune and train for a strong central leader while very young. If branches are producing so heavily that they are at risk of breaking, prune back some length. Make your pruning at a fork. Prune only after nuts have dropped, in early fall. You may also cut back old unproductive wood to stimulate new fruiting branches. Walnuts pruned in spring bleed severely.

Walnuts—Black Walnut: Native to North American zone 4, black walnuts do everything slowly and grandly. They bear late, unless grafted, but once started, a mature black walnut tree can produce nuts generously. They grow slowly; it takes them 100 years to get near full growth and 30 more to start feeling middle-aged. They get wonderfully big. The largest of the walnuts are the largest of any nut tree, except maybe the beech or pecan. They are beautiful in your yard. However, keep in mind that roots of both black walnut and butternut defend their space by manufacturing a toxin that is deadly to some other plants. The black walnut is afflicted with few diseases or insect pests. When they do get old enough to die, they’re worth a fortune for furniture making. Plant some for your grandchildren! Or great-grandchildren? Read Black Walnut for Profit by B. Thompson (1976), for more information on walnut for timber and commercial nut sales.

Planting. Varieties vary as to hardiness and pest resistance. Plant 80 feet apart in neutral soil.

Harvesting. Black walnuts only rarely lose a crop to frost. Commercial walnut growers use mechanical shakers to harvest the nuts and have to prune the trees in such a way that their machines will work, but private parties devise their own shaking systems, or wait for the walnuts to fall naturally off the tree at summer’s end. At that time there is a thick yellowish-green husk covering them. Before they fall from the tree, it’s a grass-green hull. There are recipes for a ketchup made from those green walnuts in all the old-time recipe books. I never had the nerve to try one. I chewed into a green walnut once and was puckered up for the rest of the day. If they aren’t poisonous, I can’t understand why not.

Dehulling. Best way to get those hulls off is to gather up all the walnuts in their hulls and transport them to your driveway. Use rubber gloves. The juice in the hulls that have been mashed by being walked on or some such will stain...
your fingers (it also makes a great home-grown furniture stain). So use rubber gloves to handle them. Spread them out and let the cars run over them for a while. The tires will mash those husks away without harming the nuts. In about a week the job will be done. Get out your rubber gloves again and move the walnuts indoors for stage 2 of their treatment. Don’t leave them lie in the sun and wind. It will hurt the nutmeats inside. Don’t dawdle around and delay harvesting them until the husks turn black—bad for your walnuts. (Don’t be surprised by maggots in black husks. They are there before, just more obvious in the black husks, and a routine, harmless situation.) A cement floor of a sheltered building where you can spread them out and stir them around once in a while will be perfect. A cool, darkish, well-ventilated attic would work very well, too. It’s important to dry them not too quickly and not too much.

Cracking. Black walnuts are comparatively difficult to crack and the nut meats are hard to get out whole from all the little chambers. But they sure do produce. (Heartnuts are relatively easy to crack.) The ideal is to hit the walnut hard on that sharp point enough times so that it splits from top to bottom into 4 neat sections. However, Tucker Hill, my nut consultant advises: “This is next to impossible. With a hammer in the hand of an amateur, not smashing the nut to smithereens will be sufficient accomplishment!” Practice helps. Once the shell has been cracked, Tucker advises: “Use a wire cutter to clip away the shell from the kernel. That is easier than digging out the kernel with a nut pick.”

In the December 1992 issue of The Nutshell, Tucker wrote about visiting a gentleman whose system was that he “husks them with a board and a slightly deflated back car tire, cleans them in a wringer washing machine, dries them on 5 x 10-foot wire frames, and hand-cracks enough nuts to pick out roughly 100 lb. of kernels . . . his homemade nut cracker was of his own design and one of the heaviest crackers I have ever seen . . . effective, efficient, and easy to use.”

Storing. In the shell, properly cured, walnuts will store until the next fall. You can bake the nutmeats right after cracking in a 215°F oven for 15 minutes, and they’ll keep a good long while. Or you can freeze them, or merely keep them in the refrigerator.

Walnuts—Butternuts: These are Juglans cinerea, a medium-sized variety of walnut also known as “oilnuts” and “long walnuts.” In addition to bearing nuts, they can be tapped for their sap like maple trees. They are the hardiest of the walnuts, thriving in zone 3, and the least likely to lose a crop to frost damage. Butternuts are one of the most northerly in range of the nut trees, growing well across the northern tier of the United States and even in southern Canadian provinces. English walnuts bear younger than black walnuts. And then there are hybrids in which Persian walnut tops are grafted onto black walnut bases.

Planting. Butternuts have a bushing tendency, so if you want a treelike appearance, pinch and prune to a strong central leader during the first few years. Prune a nut-bearing tree only in early fall after all the nuts have fallen off. Don’t worry about weak crotches; butternuts have such strong wood that there is little tendency to break.

Harvesting and Shelling. Your tree will start producing about the third year. The nuts grow in clusters inside a spongy, hairy husk. The husk is easy to get off. Butternuts are really hard to shell. You can wear a glove to protect your hand and stand the butternut on solid iron, like an anvil, then hit the pointed end with a hammer. In half an hour you might have a pint of nut meats. They are a little easier to shell if you first cover them with boiling water and let them soak for 15 minutes. Inside the hard shell that you hammer off, the nut parts are almost, but not quite, separated by woody membranes, like a black walnut. You have to pick the nut meats out, and they break in the process. Butternuts can be stored in a cool dry place for several months (longer if refrigerated).

Cooking with Butternuts. They are the fattiest of all nuts, good in cake or homemade bread. Just add to any recipe and cut back the shortening a trifle.

Walnuts—English (Persian) Walnut: Juglans regia is the botanical name for the Persian walnut—the more correct of the common names since this tree originated in Persia and then arrived in the colonies via English boats. So it originally needed a relatively warm climate to thrive. But now there is a Carpathian variety from Poland that can grow almost anywhere in the temperate zone up to the northern tier of the United States and even in southern Canadian provinces. English walnuts bear younger than black walnuts. And then there are hybrids in which Persian walnut tops are grafted onto black walnut bases.

Planting. English walnuts are usually self-fertile so you need only one. However, some Carpathian and black walnuts need 2 trees to make nuts. To save seed from English walnuts, harvest nuts while still in the hull. They must be chilled 6–8 weeks at 35°F or so before they’ll germinate. Plant 1 inch deep in flats to see which germinate. Transplant only during the dormant season. Or to plant seed directly outside, plant under protection from wild nut-eaters. To graft, cut scions from proven cultivars when they are at least 1 year old. Patch bud in summertime or whip graft. Stocks are best if 2 years old. You’ll find the least risk of Juglans dying back with these stocks: California black walnut, English walnut, Eastern black walnut, and the Paradox.

Walnuts—Heartnut: J. sieboldiana, or heartnut, is the smallest walnut, growing only 35 feet tall. It rarely suffers frost damage, lives long, has good disease resistance, the mildest-tasting kernel of all the walnuts, and nuts that crack unusually easily.

Temperate-Zone Fruits

“Fruit” means different things to different people. To a plant scientist, a “fruit” is a plant's seed container. So acorns, pea pods, apples, and ears of corn are all equally fruits. But to others, fruits mean delicious, soft things that grow on trees,
vines, bushes, or brambles—and which usually have seeds inside them somewhere: apples, bananas, grapes, berries, and so on. And fruits are sweet.

Maybe seeing a grumpy, tired, teething baby close its eyes in sleep is really the sweetest thing in the world. Maybe it’s hearing the man you’ve been married to for many years say “I love you,” and mean it. Maybe it’s finding out that something you’ve been worried sick about is going to be all right after all. I’m sure it isn’t anything in the recipes in this chapter.

Most true sweets have their bitter side. The sweet is so sweet because it’s such a relief after what’s come before. When I think of food sweets, my favorite thing to think of is fruits and berries. Those are the best tasting of all to me, never caused a cavity that I know of, and don’t need a thing extra in season to make them a joy to eat.

On the subject of bearing fruit, a reader sent me this quote from a Native American spiritual leader called Black Elk. I taped it to my computer (yes, now I use one and what a help it is!) until I knew it by heart.

A vision without a task is a dream. A task without a vision is drudgery. But a vision with a task can change the world!

I do have a vision, and I do have a task—several visions in fact, and thus several tasks. One of them has to be to tell how to grow all the temperate-zone fruits!

**INFORMATION AND NETWORKING:** The Harrowsmith Book of Fruit Trees by Jennifer Bennett is good on temperate zone fruits. Any library has lots more references. The Home Orchard Society is dedicated to promoting the growing of fruit-bearing plants and to preserving historic fruit varieties. Write for their newsletter and info about pruning workshops, scion exchanges, orchard tours, and rootstock training: PO Box 230192, Tigard, OR 97281-0192; 503-639-6250.

**PEACH TREE BORERS:** These are a bad problem for peach, apricot, cherry, and plum trees in places like Pennsylvania, readers tell me. They not only attack peach trees but also wild and cultivated cherry, plum, prune, nectarine, and apricot trees. You’ve got them if you find masses of tree gum that contain red-brown larval droppings and sawdust on the tree trunks near the ground. The borers eat on the roots and the inner tree bark from below the soil surface to 10 inches above it. The trees first do poorly and the leaves get off-color. Then, often, they die. The borers themselves are about an inch long. They look like worms that have brown heads and cream-colored bodies. They eat in late summer and fall, then winter in their burrows in the tree. In spring they feed again until their pupal stage, which they spend in the top inch of soil around the tree. The adult insects emerge about June. They have long black bodies except for a broad orange band (female) or yellow stripes (male). The female lays eggs on the tree and in the nearby soil. After hatching, the larvae begin boring and feeding.

The best cure is prevention. Paint your newly planted trees with exterior white latex and add a sticking agent for longer-lasting protection. Keep the tree growing at the proper rate with plenty of water and fertilizer. Any tree weakened by injury, drought, hunger, or sunburn will be more susceptible to attack by borers. If your tree does get infected you can worm it by digging up the dirt surrounding it down to 6 inches. Find the wormholes by making cuts around the damaged areas. Use a flexible wire in the burrows to skewer the worms. Do it again in 2 weeks. Fill up the holes and replace the dirt. Put mothballs or lots of ashes on the ground around the tree trunk to discourage a return visit.

**Apples**

These are the most popular temperate-zone fruit. They grow easily, store well, and have many uses. The modern apple tree is available in a wider range of sizes than that of any other fruit: from 30-foot standards down to 6-foot dwarves. However, the modern apple is also, in apple-growing areas, plagued by many pests and diseases, especially where summers are wet. It’s important to choose trees that will be most resistant to whatever pest problems are prevalent in your area. Last I heard, the Liberty was about the most disease-resistant variety available, but the heroic folks who develop trees may have an even better one now.

**VARIETIES:** There are more than 1,000 apple varieties and many nurseries that specialize in apples, some just in “antique,” old-time apple varieties, some in the most modern cultivars, some that carry both. Both Lawson’s and St. Lawrence Nurseries carry 100+ varieties. You can get a free list of “Disease Resistant Apple Varieties” from ATTRA at 800-346-9140. They also offer “Considerations in Organic Apple Production” and “Organic and Low-Spray Apple Production.” At Applesource, the wise and wonderful Tom Vorbeck sells not trees, but mail-order apples. His website, [www.applesource.com](http://www.applesource.com), includes a grower section with Tom’s suggested apple varieties for central Illinois backyard growers: 800-588-3854 (LUV-FUJI); 1716 Apples Rd., Chapin, IL 62628. You can choose apple varieties to ripen early, middle, or late in the season; apples with specialized resistance to a particular disease or to all of them; or apples with low-chilling needs suited to southern California and Florida. In fact, there are apple varieties suitable for every temperature through the temperate zone (even to -40°F!). There are apples grown especially for eating out of hand, or for cider, or for cooking, or for winter storage. And green, red, or yellow apples. And short-lived or long-lived apple trees. And tall or “standard” (a large tree that gives a large harvest), shorter standard, semi-dwarf (12–18 feet), or dwarf (6–12 feet) apple trees. The semi-dwarf and dwarf apples will fruit in containers. Standard apple trees are bigger—up to 30 feet—and thus take more room than any other standard fruit tree. And you’ll have your choice of trees that are 1, 2, or 3 years old.

**Pollinizers.** Each variety of apple has its own specifications that you’ll learn when you’re shopping for it. Suffice it to say that most regular apples need a pollinator, but most
crab apples don’t. But even the “self-pollinators” will produce better if planted near a pollinating variety. So plan to plant 2 varieties—at least unless your neighbor has an apple tree already.

**Crab Apple.** This is an apple species distinct from the regular apple. It is unlike any of the others in many ways: It has the smallest fruit and is the only apple that is not comfortably eaten raw because of its extreme tartness. On the plus side, crab apple trees are the hardest of all apples and thus are a treasure for frigid areas. They have by far the showiest spring blossoms, they are usually self-fruitful, and their fruits make excellent jelly, good peeling, and unforgettable pickled fruit. Crab apples come in both standard and dwarf sizes. When shopping, beware of ornamental varieties; their fruits are as edible as any, but usually smaller. Transcendent is a good edible crab apple. Adams and Robinson are good for disease resistance. Dolgo is the most cold-weather hardy variety. No need to thin crab apple fruits.

**Sweet Pickled Crab Apples** Wash the crab apples and remove the blossom ends. You’ll need a peck (about 2 gal) of them. Make a syrup of 1 qt. vinegar, 3 lb. brown sugar, 1 t. whole cloves, and 1 stick cinnamon. Boil. Add apples and cook them in this syrup. Remove apples, put them in a jar, and pour the syrup over them. Seal. Additional good-tasting things to add to your syrup are cider, allspice, ginger, nutmeg, and lemon juice.

**Crab Apple Preserves** Core the crab apples with a sharp knife through the blossom-end, leaving the stems on. Use 1 lb. granulated sugar and 1 c. water per 1 lb. of prepared fruit. Put sugar and water over the heat, and boil it to dissolve the sugar. Skim, and then drop the apples in. Let them boil gently until clear and the skins begin to break. Take the apples out with a perforated skimmer and pack them in jars. Pour the syrup over them and seal. Optional: slices of lemon boiled with the crab apples, 1 lemon per 3 lb. of fruit.

**Planting:** First the seeds must experience a period of chill. At least 2 months on damp paper, covered with more damp stuff, in a jar in the refrigerator should have them stratified enough to sprout. Then move them to a nursery bed. But most apples grown from seed will bear only small, sour fruit and not be worth the space. That’s why apple trees are almost always propagated from cuttings, or by grafting or budding. Standards need to be spaced 40 feet by 20 feet. Dwarfs are spaced 8 feet by 10 feet. Plant in well-drained soil. Allow full sun for strongest disease resistance and sweetest apples.

**Growing:** Maintain organic mulch plus a yearly spread of manure or rich compost for feeding. Make sure young trees get regular watering. Once they’re several years old, apple trees can make it just with summer rain if your climate provides that reasonably often. Otherwise give them a thorough, deep soaking at least once a month. Prune only while dormant. Some growers do no pruning for 2 years after planting, then prune only minimally to keep the center open. Thinning out to get better air circulation helps combat mildew in your tree. The apples grow on “fruiting spurs”—little branches that grow off bigger ones. If you prune, don’t take these out, because in the case of the apples, the fruit is grown year after year on these same spurs rather than on new wood. If you thin the young fruit to get bigger individual fruits, thin to 6–8 inches apart.

**Harvesting:** Standard apples take 5–8 years before the first fruiting and take up to 10 years to get into full production, yielding 5–20 bushels per tree per year. Once mature, however, your trees can live and fruit for as many as 30 more years. Dwarf apples fruit in 2–4 years and yield 1–2 bushels per tree. For best storing, pick them before they’re dead ripe. Don’t pick right after rain; they should be dry. You can use a ladder, but it’s safer to use an apple picker, which is a long pole with a stiff wire loop and basket on the end of it. Sort the apples while picking—setting aside bruised, very ripe and soft ones, and ones with wormholes to make into applesauce or give to the animals. When storing green apples, put the very greenest and soundest ones into storage. Don’t throw them around. If an apple falls off the tree instead of being picked, put it into a box for quick use since even if it doesn’t show, it has been bruised and will spoil more quickly. You can make good cider out of the “windfalls.” In fact, if it’s cider you’re making, harvest by shaking the tree! If wasps are active around your tree, pick late in the day to avoid grabbing a wasp along with the apple.

**Preserving Your Apple Harvest**

**Root Cellar Storage.** The keeping qualities of raw apples vary. The best apples for storing are said to be Yellow Newtown, Winesap, Arkansas, and York Imperial. In our orchard we have early apples that come on at the same time as the apricots, and, of course, we don’t worry about raw storage for them. What we don’t eat we can as applesauce or apple butter. They are better applesauce apples than storing apples anyway. Ditto for the next crop of apples. The last crop consists of apples that don’t turn red until fall is really on, and they aren’t picked until after the first frost. It is October as I write this, and I have only just begun to harvest these red apples. These are the ones we store for winter. Obviously, the later you put them into storage, the later you have them. They keep better on the tree than in the basement. Only when they really show a determination to fall from the tree do I pick in earnest. We also have a big green late apple. It gets very large, never does turn red, and is very good. These apples are so good we always just eat them up.

Cool storage is vital. It just amazes me how fast the apples start to shrivel, lose that nice crisp texture and flavor, and plain old rot when we bring in a box from the storage shed to the kitchen—literally within a couple days. The secret is keeping them cold but not frozen. In warmish weather they tend to rot first at the bottom of the box. Adjacent apples won’t catch the rot very fast but eventually they’ll soak up a noxious rotten flavor, so picking over the apples—but carefully not to bruise them—is a good idea once in a while. Apples on top that have been touched by frost will be brown and then bad in the frosted place.

A way to help keep your apples cold is to give the cellar access to frosty night air and then shut it up tight during the daytime. With the best of luck they will even keep until spring. But the apples shouldn’t freeze. You could insulate your boxes under straw in the barn, or inside barrels underground, with a straw and dirt covering. Another way to store apples is in a big box lined with crumpled newspaper and then a heavy quilt or some such. My apples are stored in cardboard boxes in the bunkhouse under an old mattress. The children enjoy fresh raw fruit so much when it is out of season. I bring apples into the house as needed. We
\section*{FREEZING APPLES FOR PIE}

For apples to use in making pies and so on, just wash, peel, core, and slice them. About 50 lb. of apples will make about 35 frozen pints. To keep them from turning dark, quarter (or slice) them into a solution of \( \frac{1}{2} \) c. salt per gal. water. Or else dunk them into boiling water for \( \frac{1}{2} \) to 2 minutes. Then drain the apples, rinse them under cold water, and drain again. Method 1: Scald, drain, chill, cover with a thin syrup (\( 1 \) c. sugar per quart of water plus \( \frac{1}{2} \) t. ascorbic acid), leave headspace, and freeze. Or Method 2: Mix \( 1 \) qt. apple slices evenly with \( 1 \) t. ascorbic acid and \( \frac{1}{2} \) c. sugar. Then put into plastic bags or freezer boxes, seal, and freeze. Or Method 3: No sugar. Just pack 'em plain. The slices break apart quite easily while still frozen for making apple pie or crisp, or you can add a small amount of water and make applesauce. Or Method 4: Freeze whole apples, unpeeled. Just wash, put into plastic bag, seal, and place in freezer. To use frozen whole apples, thaw under cold running water until they can be peeled. Then remove the core and slice. (Work fast; an apple that thaws before peeling darkens.)

\section*{FREEZING APPLESauce}

Applesauce turns out nicer, I think, canned than frozen, but you can freeze it by just making it, then cooling, packaging, and freezing.

\section*{PINK Applesauce}

Use red apples and leave the skins on while cooking. Proceed as above. Strain.

\section*{APPLE-Rhubarb SAUCE}

A real treat! Make cooked rhubarb sauce in the spring and freeze it. When the apples come on, take it out, combine half and half with applesauce, and enjoy.

\section*{Drying Apples}

You have to slice them; they aren't dried whole. Fully ripe sweet apples are ideal. Usually they are peeled and cored and what’s left is made into doughnut-type rings about \( \frac{1}{4} \)-inch thick to oven dry, \( \frac{1}{4} \)-inch to sun dry. Let the slices fall into cold water while you are working to prevent “rusting.” \( \frac{1}{4} \) c. lemon juice or 1 t. ascorbic acid per 2 c. cold water. If your apples are small, wormy, or too mealy to make into doughnut rings, cut into slices of whatever shape you can. Old-timers then strung them on a thread and hung them in the sun, but now we usually just spread them out on a surface. Using an oven or dehydrator, dry them at \( 140^\circ F \) on a cookie sheet—turning once in a while—until they are leathery.

\section*{Apple Leather}

If apples need sweetening, add it. Cinnamon or coconut are good mixed in: 4 t. cinnamon or \( \frac{1}{2} \) c. coconut per 2 c. puree. Start by peeling, coring, sectioning, and grinding the apples in your grinder. Be sure and catch the juice that runs out. Add \( \frac{2}{3} \) c. cider (juice) per gallon of ground apple, and then cook the whole mixture over low heat. When it is boiling and has cleared some, sweeten it if needed, and then spread it out in sheets to dry.

\section*{Cooking}

Apples are one fruit that you will have raw for a very considerable time out of season. That gives you so many great possibilities for ways to use them. I like apples in salads, apples in puddings, apples in any dessert, fried apples, and baked apples.

\section*{Baked Apples}

Peel and core the apples (or don’t peel if they’re on the small side or never sprayed). Place in a shallow pan with a piece of butter and a dab of honey in the center of each apple. Sprinkle with cinnamon. Add 3 cups water to the pan and bake, covered, at 375 F. until tender and juicy. Or, if you bake uncovered, taste often. The apples will be nearly transparent when done. Serve with whipped cream. Or the traditional “hard sauce” of hot brandy, butter, and sugar. For a really special dish stuff the apple center before baking with pitted, mashed dates. Or raisins. Or nuts. Or both.

\section*{“APLETS” CANDY}

You’ll need 2 c. cold homemade, unsweetened applesauce, 2 c. sugar, 2 T. unflavored gelatin, \( \frac{1}{2} \) c. cold water, \( \frac{1}{2} \) c. chopped nuts, a few drops of orange extract, and some powdered sugar. Sprinkle the gelatin into the cold water and let it stand. Put the applesauce through a sieve to make sure it’s fine, then add the sugar, and cook until it gets very thick. Remove it from the stove and add gelatin. Stir well. Add nuts and flavoring, mix, and pour mixture into a buttered 8-inch-square pan. Let stand overnight but do not refrigerate. Next day cut into squares and roll them in the powdered sugar. This keeps well and can be made a week or more ahead of the holidays.

\section*{“COLETS” CANDY}

Use the Aplets recipe, substituting the same quantity cooked and sieved dried apricots for the applesauce.

\section*{Apple-Plum Butter}

Use from 2 to 3 times as many apples as plums. Cut up the fruit and cook in a little water until tender. Then put it through the colander. Add sweetening. Continue cooking until the butter is thick enough to serve the name. This is Mike’s favorite. He likes it on waffles or pancakes or toast, and so do I and the children.
APPLE KETCHUP  Peel and quarter a dozen round, tart apples. Stew until soft in as little water as possible. Sieve them. For every quart of sieved apple, add 1 c. sugar, 1 t. pepper, 1 t. cloves, 1 t. mustard, 2 t. cinnamon, 2 medium-sized onions—chopped very fine, 1 T. salt, and 2 c. vinegar.

MAKING CIDER: You'll need about a bushel of apples to make each 2–2½ gal. cider (or "juice"). Any kind of apples can be used, and you can try different blends for the sweetness-tartness qualities you prefer. Professional cider makers or serious hobbyists can get really picky about how much of what kind of apple, but hey, it's all apple juice. The important thing is to find a way to make use of what you have. In general, good eating apples are also the best cider apples. The only apples you seriously shouldn't use are sprayed apples, partly rotten apples, or apples that have been lying on the ground very long.

UNPRESSED CIDER  Even if you don't have a cider press you can make cider. Clean and cut your apples. Put them through a grinder or chopper, saving all the juice, and then squeeze your grindings through a strong cloth bag.

Cider Presses. In these modern times you may already own an electric, centrifugal juicer, which may be fine if you want to make just an occasional 2–3-gal. batch. It may or may not be heavy-duty enough to make large amounts of cider. And then again a cider press doesn't require electricity. Companies that carry supplies for home wine-making carry fruit presses. The press can also be used for crushing large amounts of other heavy fruits to make juices: grapes, peaches, pears. For larger batches you can get ever-larger sizes of presses, more expensive as they get bigger. Or you can make an apple press out of a screw or small hydraulic jack (a 1-ton jack for a bushel-press). A typical old-time press that holds a bushel of apples produces about 2 or 3 gal. cider for each pressing.

Cider presses come in various sizes. The smallest one may be called a "fruit press" and can be used to make cider only if the apples are preground. The fruit press is also good for juicing berries, cherries, soft fruit, or precrushed fruit. This is often sold as a "cider press." A big cider press has an electric motor that can make 30 gal. of cider an hour. A grinder is part of that machine. Or you can get a manually operated cider press with a grinding attachment (also manual). Pre-grind them. Whole apples tend to tear up the press. Happy Valley Ranch specializes in mail-order cider presses; free catalog: 16577 W. 327th St., Paola, KS 66071; 913-849-3103; fax 913-849-3104; hvr@micoks.net; www.happyvalleyranch.com.

Preparing the Apples. Wash (!) your apples and cut out the wormholes. Usually its handiest to cut all the apples in 2 pieces as you go, in order to get at the wormholes. Cut out rotten spots or scarred places where the apple rubbed against the tree. But it isn't necessary to take out the seeds.

The Pregrinding. The press I have will not extract juice from apples very well if they are whole or even in chunks. If you have a press or pressing system that requires a pre-ground apple, then the apples should be chopped to a fine pulp or mashed before squeezing. You can use a hand food chopper, a meat grinder, a food processor, or a special electric grinder for making large quantities of apple pomace (the ground apple is called "pomace"). Grind it twice if you can't get it fine enough the first time through. Save the juice that results from grinding to add to the cider later. You also need a wooden pestle to use for a follower on the grinder contents rather than risking your fingers. You put the mashed fruit in a cheesecloth or nylon mesh bag and then put the bag into the press. Or else line the press with that cloth.

Pressing Out the Cider. Put the cleaned and cut apples into the metal cylinder and press. There is a crank device to put the pressure on. Have a nonmetal container ready to catch the juice. This process can't be rushed. Apply pressure, and then wait until the juice stops coming. Now apply still more pressure. The more patient you are about pressing and waiting, the more cider you'll get, and the clearer it will be. You can drink it the moment it comes out of the press if you like. Or heat a cup of freshly pressed cider, and add a dash of powdered spice to it!

The Filtering and Settling. You could use it strained or unstrained. If you don't strain it, the bottom couple inches will collect a visible pulp. If you want to strain it, just pour the juice through a couple thicknesses of cheesecloth. Rinse your cloth whenever the holes clog.

Before canning or freezing cider you can let the freshly pressed juice stand, and the pulp will gradually settle out. To start, pour the juice through a cheesecloth or diaper or such into its settling container. This should be a pan, bowl, jug, or bottle made of crockery, stainless steel, glass, or unchipped enamel—never regular metal because the juice is acidic. Keep the juice below 40°F for 12–36 hours—long enough to get the cider clear enough to suit you. (It takes about 4 days to get it absolutely clear, and by then you're risking some fermentation.) But some people prefer their apple juice with some sediment in it so maybe you won't want to bother with this step at all.

Storing Cider. Cider doesn't need any sweetening. You can drink it fresh. If you keep it refrigerated, below 36°F, it might stay fresh as long as 2 weeks. But store cider is pasteurized, treated with chemicals for preservation, and then canned. If you don't either freeze or can the cider, sooner or later, depending partly on the temperature but maybe as soon as 3 days, you will have first fizzy cider and then "hard cider." You need to preserve it before that stage unless you're making apple wine—and to do that you need more.
instructions than what I'm providing. You can freeze it, use it as the liquid when canning other fruits, or can it straight. When you can with apple juice, you can reduce or eliminate the sugar.

Freezing Cider. You don't need any heat treatment. Just pour it in containers and put in your freezer. Figure that it will expand about 10 percent when frozen, so you don't break your container. Plastic containers or glass jars with plenty of headspace are all right. You can line tin cans by putting a plastic bag inside them. Twist and tie the bag over the top of the juice and freeze it that way, too. It will keep frozen as long as a year.

Canning Apple Juice in Jars. This recipe is also good for citrus, grape, or pineapple juice. Make your juice. Add 1 c. sugar to 1 gal. juice, if desired. Heat to simmering (185°–210°F). Pour hot juice into hot jars. Leave ½-inch headspace. Process in boiling water bath. Process pints and quarts for 5 minutes at altitudes under 1,000 feet, for 10 minutes at 1,001–6,000 feet, and for 15 minutes above 6,000 feet. If you are packing it in ½-gal. jars, and that is an option with these fruit juices, then you process 10 minutes at lower than 1,000 feet, 15 minutes at 1,001–6,000 feet, or 20 minutes if above 6,000 feet.

Pasteurizing Apple Juice. Use your dairy thermometer to get the temperature right. Heat it to 170°F and keep it there for 10 minutes. If a scum forms, skim it off. You don't want to get it hotter or keep it hot longer because you'll get a cooked flavor, and it won't be cider to be excited about. Have ready your spotlessly clean bottles, jugs, or whatever, and caps. Pour the hot cider immediately from your pan into the preheated, sterile bottle and lid or cap at once with scalded lids or caps. Now set the bottle into a hot water bath of 165°F for 5 minutes. Next move the bottles to a tub or sink containing lukewarm water for 5 minutes. Then cool them down some more under cool running water. The reason for such gradual heating and cooling is so your containers won't break. The best caps are screw caps fitted with rubber gaskets rather than cardboard linings. The rubber gaskets give you a much better seal.

CIDER TEA. Half cider and half tea, this drink is flavored with lemon juice and sweetened to taste. Or combine 4 c. cider, 2 c. tea, and the juice of 2 oranges and 1 lemon. Sweeten to taste.

CIDER BLENDS. Mix cider half and half with plum, pear, cherry, or raspberry juice. Combine before freezing if possible.

CIDER ALE. Combine 1 c. orange juice, ¼ c. lemon juice, 2 c. cider, and 2 c. ginger ale. Sweeten to taste.

CIDER PUNCH. Combine 8 c. cider, 2 c. cranberry juice, the juice of half a lemon, and 4 c. ginger ale. Sweeten to taste.

CIDER ICE. Dissolve 1½ c. sugar in 4 c. cider. Add 1 c. orange juice and ¼ c. lemon juice. Mix and freeze.

OLD-FASHIONED APPLE CIDER BUTTER. This is the traditional apple butter made of pared apples boiled down with cider. Boil 6 c. apple cider in an enamel or stainless-steel pan. (Optional: For extra redness start with 12 c. cider and boil it down to 6 c.) While the cider is boiling down, core and quarter about 10 lb. of apples. Add apples when the cider is ready and continue cooking slowly until they're tender. Put it through your colander. Put your butter back into the pan and add 1½ c. brown sugar (or more to taste)—it depends some on the sweetness of your apple variety. Optional: Add ½ t. ground cinnamon, ¼ t. allspice, ¼ t. cloves, and a pinch of salt. Continue cooking over very low heat, stirring a lot, until the cider and sauce do not separate when a spoonful is placed on a plate. Then pour into containers for canning or freezing.

Apple-Pear

See “Oriental Pear.”

Apricots

This wonderful fruit tree gives a large harvest of fruits that are somewhat like small, orange-colored peaches. Apricot trees live long; old ones look gnarled and wise.

VARIEITIES: Like apples, apricots tend to have disease and pest problems. Plant the most resistant varieties. They come in either standard (20–25 feet), semi-dwarf (12–15 feet), or dwarf (4–8 feet) sizes (which will fruit in containers). The fruits of all varieties are very similar; the differences are in chilling requirements, etc. with one big exception: the edible-kernel apricot or “sweet kernel.” All apricot kernels (the nut inside the pit) are high in cyanide and basically poisonous except for these varieties, which have an almond-like edible nut, and are also listed here under nuts.

CLIMATE: There are apricot varieties suited to a range of temperate zones. Because they need winter chilling to break dormancy, no apricot varieties will grow in subtropical climates. Manchurians are shrubby types that are the most cold-hardy. Choose a type hardy enough for your area and one that blooms late enough that most years your crop will be safe from frost-kill (29°F or lower). Zones 4 and 5 are marginal for apricots unless you use the Manchurian, have an ideally protected planting site, or grow dwarfs in containers, which you can bring in during severe cold or during untimely spring frosts.

PLANTING: Accomplish this by cuttings, budding, or grafting. Planting the seeds just won't pay off. Plant in well-drained soil where each tree can get full sun: standards 20 feet by 20 feet, dwarfs 12 feet by 12 feet. Keep in mind that apricots tend to grow as wide as they are tall. Don't plant on land that has had melons, peppers, potatoes, raspberries, strawberries, or tomatoes growing there for the past 5 years, as the apricot can pick up a disease from those plants. Like other temperate-zone fruit trees, apricots bloom in early spring. Some apricots need a pollinizer tree and some don't, but even the ones that don't usually bear better with cross-pollination, so plant 2 varieties.

GROWING: Apricots can usually make it without many amenities. You can choose not to prune, not to thin, and not to mulch, and probably still get a crop. Moderation is the secret to apricots. An organic mulch including some compost helps keep the roots warm in winter and cool in summer and nourished always, but too rich a diet can result in diseases and splitting. If your summer is dry, they need a monthly deep watering, but too much water if your soil doesn't drain well can make them sickly. Like apples, apricots bear their fruits on “fruiting spurs” that produce for 3–4 years. The conventional wisdom is that some conservative annual pruning will increase harvest, and that hand-thinning will give you larger fruits. I've missed pruning and gotten fruit anyway, and I don't think the thinning is worth the effort if the fruit is for home use rather than competing in a supermarket produce aisle.
Scab. Apricots are subject to a fungal disease called “scab.” That's what it looks like, and all unsprayed trees have more or less of it—domestics often more than wild trees for some strange reason. You can trim off the scab to eat the fruit raw. To can it, either trim the blemishes or go ahead and can the fruit, scab and all. Given a good cooking your apricots will be just as delicious as if the scabs weren't there. The scab is not harmful to eat, softens up, and is hardly noticeable for family use. Beats eating poisons. This is called peaceful co-existence.

Harvesting: Apricots take about 3 years to begin fruiting. Harvest time is a wonderful crisis that usually comes in July. Mature standards yield 3–4 bushels, dwarfs 1–2 bushels. The fruit ripens all at once. You know it's ripe when the color has gotten bright and the fruit is soft. Once ripe, apricots are highly perishable, so the next challenge is a crash effort toward eating up or preservation: by canning, freezing, drying, making jelly or jam, or juicing into “nectar.” You can't get ahead of the game by picking green fruit, they look and feel leathery and no moisture comes out at all. Spread the drying tray (or whatever you use) and half orange or grapefruit juice. É

Canning: Wash the apricots, cut them in half, and take the pit out. (If you leave in the pit—which contains cyanide—your syrup will get cloudy and the fruit won't taste good.) Raw Pack. Pack your halved apricots into overlapping layers, cut side down, in clean jars. Boil syrup (or any fruit juice or plain water). Leave ½-inch headspace. Put on lids. Process in a hot-water bath. At altitudes up to 1,000 feet, process pints for 25 minutes, quarts for 30; at 1,001–3,000 feet, process pints 30 minutes, quarts for 35; at 3,001–6,000 feet, process pints 35 minutes, quarts for 40; at 6,000 feet and higher, process pints 40 minutes, quarts for 45.

Hot Pack. Heat the halved apricots in your chosen liquid thoroughly through to boiling. Boil 5 minutes. Then fill hot jars with the hot fruit, and immediately process in a boiling water bath. At altitudes up to 1,000 feet, process pints for 20 minutes, quarts for 25; at 1,001–3,000 feet, process pints 25 minutes, quarts for 30 minutes; at 3,001–6,000 feet, process pints 30 minutes, quarts for 35; at 6,000 feet and higher, process pints 35 minutes, quarts for 40.

Freezing: Wash the fruit, cut in half, take out the pit, peel or not as you prefer. Twenty pounds of fresh apricots will make about 25 pt. frozen apricots. Method 1, halves: Cover with syrup (or any fruit juice, or plain water) and freeze. Method 2, mashed: Steam the mashed apricots about 4 minutes, mash, sweeten to taste, pack, and freeze.

Drying: Wash fruit, cut into halves, remove pits. Do not peel. Optional: Preserve color by dipping into a solution of 1 t. ascorbic acid per 1 c. cold water. Now soak 10–15 minutes in mildly salty water (2–4 T. salt per 1 gal. water). Drain. Lay on tray with the pit side up. They're done when they look and feel leathery and no moisture comes out when you squeeze.

Apricot Leather. Wash and pit the fruit. Puree your apricot halves (leaving the skins on). To each cup of mashed apricots, add 1 T. honey and ¼ t. cinnamon (or any other sweetening or spice that suits you, like a dash of nutmeg or nothing at all). Spread the drying tray (or whatever you use) with plastic, or oil it. If you use plastic, make sure some hangs off the edges. Spread your fruit paste on the surface and set it out to dry. When it's done you can just peel the plastic backing away.

Apricot Leather and Juice. Steam or cook slightly 1 gal. pitted apricots. Add 1½ c. pineapple juice. Drain off the juice—the more juice you get off, the quicker what's left will dry. Sweeten the pulp that's left if you want. Almond extract is a good flavoring; add 3 t. Can the leftover juice. Spread out your pulp to dry.

Dried Apricot Sauce. Chop 1 c. of dried apricots. Cook with about 2 c. water until tender. Then add 1 t. lemon juice, and sweeten to taste. Add a little more water if it turns out too thick, or cook some more if it's too thin. Or use any other dried fruit.

Apricot Juice. Pit and quarter the apricots. Bring to a boil in just enough water to prevent scorching. When tender, mash with a potato masher and then press through a sieve or colander. This is a "puree." (Optional: add 1 T. lemon juice per 3 c. puree.) For juice, strain again through something finer. Sweeten, if desired. Incidentally, 1 lb. apricots is approximately 10 whole ones or 2 c. chopped or crushed apricots.

To can the apricot nectar, use applesauce processing times. Apricot juice dilutes to taste very successfully, same as grape.

Apricot-Citrus Juice. Combine half apricot puree and half orange or grapefruit juice.

Apricot Punch. Combine 1 part apricot juice or puree with 2 parts any other juice.

Apricot Nectar from Canned Apricots. Blend or puree 1 qt. canned apricots. Add water to thin, if needed. Serve right away.

Cherries

This fruit in all its varieties is a favorite of mine! Cherries grow in zones 4–9. Sour cherries are hardier than sweet, able to handle more cold, and do well in the northern half of the United States. Sweet cherries appreciate a mild, even climate, such as that around the Great Lakes or in the Pacific Northwest. But if you have a bit of sheltered land you can sometimes sneak them into harsher zones. Chokecherries are wonderfully hardy, growing on mountain sides and in Canada where almost no other fruit tree can make it.

Varieties: Cherries come in several basic varieties: sweet, sour, and hardy. In general when people say "cherry" they mean sweet or sour. Among the sweets and sours, you can also choose among early, midseason, or late-fruiting trees. Better yet, plant a series, and have fresh cherries for months! The Sweets. These fruits can be black, yellow, or red in color. The standard-sized trees take 6–7 years to first fruit, need 25 feet by 25 feet orchard space, and get 25–35 feet tall (make good shade trees!); semi-dwarfs 10–15 feet tall; dwarfs 6–8 feet tall. Sweet cherry dwarfs take 4–5 years to fruit, and can be grown and will fruit in containers. Sweet
cherry trees tend to grow right and need little pruning.

**The Sours.** Compared to sweets, the sour varieties, also called “pie cherries,” are more disease-resistant, more hardy for cold climates (hardy enough to make it “wild”), fruit a couple years sooner, and require less room. The bad news is that the fruit is sour-tasting, not so pleasant for eating any way except in pies or preserves. Sour standards grow 15–20 feet tall, the dwarfs, 8–10 feet. “Dukes” are hybrid sweet–sour cherries, less sour than the sours, harder than the sweets.

**The Hardy Cherries.** These are the chokecherry, sand cherry, and bush cherry. The importance of them is that they can be cultivated in places where so few other fruits can. All 3 are very tart. You can use the same recipes interchangeably for any of them. Can and freeze according to sweet or sour cherry recipes. (Recipes follow.) The bush cherry grows on bushes that are 4–5 feet high. Like the other 2 hardy cherries, it can be grown where sweets and sours can’t, even in the Dakotas and Alaska. Sand cherries can grow in Alaska, Canada, and the northern United States.

Chokecherries grew wild where I lived in Montana as a little girl. They’re a native, wild cherry tree. People who haven’t grown up with chokecherries generally don’t appreciate them much at first. They grow on a bushy sort of tree in places cold enough that you really appreciate any kind of fresh fruit. They come on in the fall after the frost, and for weeks on end on the way to and from school, walking or riding my pony (it was always one or the other for the 2-mile stretch) a pause to refresh at the chokecherry grove was my pleasant stop along the way, for the fruit stays on the tree quite a while. The chokecherry pit is very large in relation to the tiny cherry-like flesh around it. You spit out the pits.

**Note:** The seeds are poisonous (contain a cyanide). Don’t ever grind or use the chokecherry seeds or can chokecherries with the seeds in. The leaves of the tree are also quite poisonous, so don’t try making tea with them.

The flavor of chokecherries is so sour (“choke”) that it will pucker you up, but, once you’ve learned to endure and even love chokecherries, you eat them anyway, pucker up, spit out all the seeds, and reach for another handful! You can buy started chokecherry trees from some mail-order nurseries and hometown nurseries.

**Planting Cherries:** Graft or bud. Cherries need a pollinator tree except for the sour cherries, which can usually self-pollinate. The pollinator needs to be a different variety of cherry—and make sure you have 2 that bloom at the same time. But not all varieties will pollinate all other varieties. So before you buy, consult about the pollination aspect! Prune the young cherry once for good shape. Keep in mind that if it’s a standard, it needs to be climbable. After that, prune in mid-June, if at all.

**Harvesting:** Standard cherries start bearing 3–5 years after their final transplanting, but they’ll keep growing and increasing their harvest for another 10–20 years. The yield of a mature standard sweet could be up to 3 bushels; sours, 2–2½ bushels. There’s no such thing as a really dwarfed cherry though. So if you raise cherries, you’re going to be doing some “cherry picker” picking. Pruning off the top of a cherry tree won’t increase cherry production down lower, so don’t try it. Let the birds have the high ones and you take the low ones. Harvesting cherries is work, but they’re worth it.

**Birds.** I take my biggest losses to the birds. They love cherries. It helps to have predator birds to keep a balance in your ecosystem; in so many places birds of prey are nearly extinct. And some growers plant mulberry trees around or among their cherries because birds like that fruit even better. Commercial cherry orchards have automatic, periodic “cannon” noisemakers. Private folks sometimes throw bird-proof netting over the cherry tree and that works the best of all if you don’t mind the look of it.

**Preserving:** Sweet cherries are wonderful canned, frozen, in jam or jelly, dried, or eaten fresh. Sour cherries are rather sour for raw eating, but they make great pies and jam. The cherry pitter is an excellent invention, especially for those of us who like to dry cherries! A typical pitter can pit a pound of cherries in less than 5 minutes. You can order one from Lehman’s, Box 41, Kidron, OH 44636.

**Canning Cherries (Sweet or Pie):** Cherries can be canned with or without pits. I used to think it was insane to go to all the work to take out the pits when the kids could spit them out so easily and the flavor was fine with them in. But with those newfangled cherry pitters, it’s a more realistic option. I still prefer them whole though. I put up over 100 qt. of cherries last year. They contained an occasional stem or leaf because I put the children to work packing for me, but despite that, they looked very attractive and tasted fine. Cherries can more easily and nicely than any other fruit except maybe peaches. I give canned cherries as gifts sometimes to visitors—I’m that pleased with the product. That’s sweet cherries. Canned sour cherries are . . . sour and not pleasant unless you do something extra with them, like stick them in a pie.

**Hot Pack.** Add ½ c. water, juice, or syrup per quart cherries. Bring to a boil in a covered pan. Pack hot cherries into hot jars. Cover with cooking liquid, allowing ⅜-inch headspace. Process in boiling water bath. At altitudes to 1,000 feet, process pints for 15 minutes, quarts for 20; at 1,001–3,000 feet, process pints 20 minutes, quarts, 25; at 3,001–6,000 feet, process pints 20 minutes, quarts, 30; at 6,000 feet and higher, process pints 25 minutes, quarts, 35.

**Raw Pack.** Pack cherries into jar. Shake jar to settle them down. Cover with boiling syrup. Process in boiling water bath. At altitudes to 1,000 feet, process pints or quarts for 25 minutes; at 1,001–3,000 feet, process pints or quarts 30 minutes; at 3,001–6,000 feet, process pints or quarts 35 minutes; at 6,000 feet and higher, process pints or quarts 40 minutes.

**Maraschino Cherries** Wash 2 lb. good ripe, but not overripe, Royal Ann cherries. Combine 1 c. limewater (from a drugstore) and 4 c. cold water, pour it over the cherries, and let them soak 6 hours. Now drain cherries, rinse well, and pit them. Combine 3 c. sugar, 1–½ c. hot water, and 2 T. red food-coloring. Heat to boiling and add the pitted cherries. Let them cook on low heat for about 10 minutes. Cool and let rest in the refrigerator until the next day. Now reheat to boiling and stir in 1 T. almond extract. Then hot-pack the cherries in hot, sterilized jars—half-pints only—together with enough syrup to cover. Use cherry canning instructions.

**Chokecherry Jelly** To 3 c. chokecherry juice, add the juice of 2 lemons and 3 c. sugar. Boil at least 25 minutes, or until a drop of juice on a saucer will jell. Pour into jars and seal. Half crab apple, half chokecherry also works nicely. And those are 2 fruits that go together; those and gooseberries will grow in the high mountain country where other fruits won’t.
QUICK CHOKECERRY JELLY  You'll need about 9 half-pint jelly jars for this. Combine 3 c. chokewerry juice and 6 1/2 c. sugar, and bring to a boil, stirring constantly. Stir in 1 bottle liquid fruit pectin. Bring to a boil again and boil hard 1 minute, stirring nonstop. Take off heat. Stir and skim 5 minutes. Now pour into jars. Adjust lids. Process in a waterbath canner for 5 minutes.

VIRGINIA'S CHOKECERRY SYRUP  This wonderful, unusual-tasting pancake and waffle syrup was one of my mother's specialties. Here is my friend's recipe for it: Combine equal parts of berries and boiling water. Mash berries thoroughly with a wooden mallet or spoon. Squeeze pulp through a cloth supported by a colander. Combine equal parts juice and sugar. Bring to a boil. If you like it thicker, boil it down to the density you want. Another way is to combine water and berries and cook a few minutes, then mash with a mallet and proceed as above. Some cooks add pectin to the pulp—1/2 box to 6 c. juice—boil and then add sugar. It hastens the process. Get it thick enough and you'll have jelly.

CHOKECERRYAPPLE BUTTER  Combine 4 c. apple pulp and 2 c. (seedless) chokewerry pulp. Mix well and heat to a boil, stirring carefully. Add sugar to taste and 1/2 t. almond extract. Ladle into hot jars. Put on lids. Process by applesauce times.

SAND CHERRY JELLY  Use 2 c. sand cherry juice, 1 c. tart apple juice, and 1 1/2 c. sugar. Use the chokewerry jelly directions.

SAND CHERRY JAM  Cook fruit with water to cover until soft. Put it through a sieve. Measure. Add an equal quantity of sugar. Simmer until thickened.

FREEZING CHERRIES:  First wash them. Pit cherries you'll want for salads or cooking. Leave some unpitted for eating. You can even freeze them plain with the stems on! For cherries frozen in a syrup you can freeze covered with apple or pineapple juice, or any sweet syrup (such as 2 c. sugar per 1 qt. water plus 1/2 t. powdered ascorbic acid), or a sprinkle of sugar. Lemon juice is good in there, too.

FREEZING SOUR CHERRIES FOR PIES:  Pack 1 qt. sour cherries with 3/4 c. sugar, thoroughly mixed until sugar dissolves. Fifty pounds of cherries make about 35 pt. for freezing.

DRYING CHERRIES:  Wash, pit, and halve the cherries or chop or leave whole as you prefer. Place halves or sections sticky side up, spread out. Dry at 115°F in your dryer or at 140°F in your oven. Stir once in a while. They don't need to be turned. They will be chewy when dry. Drying cherries takes up to 36 hours in the oven or dehydrator, possibly significantly less, or 1–2 days in the sun. They come out sort of like raisins. And, in fact, you can substitute dried cherries in any recipe that calls for raisins, or add to any baked goods, or stew them up like stewed prunes.

CHERRY ICE  Pit 1 1/2 qt. cherries. Mash them with a potato masher as well as you can. Add 1/4 c. honey and the juice of 1 lemon. Mix well. Freeze, stirring occasionally since it freezes first on the sides of the bowl and you'll want to pull that to the center. Serve with homemade whipped cream, slightly sweetened.

CHERRY JUICE  Stem, sort, and wash your cherries. Drain and pit. If the cherries are red, crush them, heat to 165°F (don't boil), and strain the juice through a jelly bag. If they are a white variety, grind and press them for juice without heating them. Cool, let stand overnight, and pour off the juice to be your cherry juice or else strain it through a bag. Sweeten it if you think it's necessary. Sweet cherry juice doesn't have the flavor and tartness of sour cherry juice. Adding some sour cherry juice will improve your product if you are working with sweet cherries.

QUICK CHERRY DRINK  Mash through a colander 1 qt. very ripe pitted cherries. Add 1 qt. water and the juice of 1 lemon. Sweeten to taste. Strain and chill. Serve with ice.

OLD-TIME CHERRY PUNCH  Combine 9 c. water and 9 mint leaves. Simmer 5 minutes and strain. Add sweetening and cook 5 minutes. Cool. Combine the mint tea, 2 c. orange juice, 2 c. lemon juice, 2 c. cherry juice, 2 c. pineapple juice, and 4 c. regular tea. Mix and let rest an hour. Serve chilled. It makes a lot.

SAND CHERRY–RHUBARB PIE  Combine 1 1/2 c. pitted sand cherries and 1 1/2 c. diced rhubarb (or blueberries). Mix in 1 c. sugar and 1 T. flour. Place in pastry-lined pie dish. Dot filling on top with 1 T. butter. Cover with pastry. Bake at 425°F until done.

Elderberries

These resemble chokewerry, only they are even smaller. There are lots of elderberry trees around here. Under natural conditions elderberries grow at lower elevations, chokewerry at higher ones, but they both like mountains and the sides of canyons. Elderberries are on the sour side. They have a lot of seed, which you sort of collect in your mouth until there are enough to bother spitting out. Or go ahead and swallow them. Elderberry blossoms are listed in Chapter 5 for tea-making. There are red elderberries and blue ones. The blue are best. They grow up to 30 feet tall.

NOTE: The sap of the red elderberry is very poisonous. Even the berries taste foul to the point of being inedible. And some varieties of elderberries must be thoroughly cooked or they're poisonous. Consult an old-timer if in doubt.

Here's what Criss Wilhite, from Fresno, CA, wrote me about elderberries: "Another thing we dry is elderberries. We go to the mountains in August and cut bushes of elderberries and elderbloom. We dry the elderbloom for tea. We dry the berries on their stems. It takes only a few days. Then we remove the woody stems and forget about the smaller ones. The berries this way are great in home-grown and ground cornmeal mush or muffins or any baked goods. Elderberry juice is great to mix with apple juice or sauce. We also make elderberry–gooseberry juice."  "Elderbloom" is the flower petals.

ELDERBERRY JELLY  Remove large stems from elderberries. Place about 3–1/2 lb. ripe berries in a large pan. Crush, cover with water; and cook on low heat about a quarter hour. Strain to get elderberry juice. Measure juice. For each 3 1/2 c. juice (you can stretch it with apple juice), add 1 1/2 c. fresh lemon juice (strained). Heat that combo. Add 7/8 c. sugar, and boil, stirring constantly. Add 1 package powdered fruit pectin and boil hard 1 more minute. Take off heat. Skim off foam, pour into hot, clear jars. Cover with paraffin immediately. Or put lids on and process in boiling water bath 5 minutes.

ELDERBERRY TEA  Use 4 c. fresh ripe berries and 2 c. water. Stir, mash well, and strain, squeezing to get all the
juice you can. Freeze or can. When wanted, let simmer a bit. Sweeten with honey. Dilute to taste.

**Elderflower LEMONADE** Gather elderflowers in June or July when they are in best bloom and remove from the stalks. Slice a whole lemon thinly into a pitcher. Place 4 large heads of elderflowers face down in there, and pour 4 c. boiling water over. Cover with a cloth and let rest and cool about 12 hours. Next day, strain off the solids, add sweetening to taste, and serve.

**Elderflower TEA** Pick blossoms in full bloom. Use fresh, or dry and store. (See Chapter 5.) At cold or flu time, put 1–2 t. in a cup. Pour boiling water over. Strain. Add honey to sweeten.

**Elderflower FRITTERS** Start with 10 elderberry blossoms with stems. Dip the blossoms in clean water for a few minutes. Shake off the mix. Water 3/4 c. flour, 1/4 t. salt, 3 beaten egg yolks, and 1/2 c. milk. A tablespoon of rum or brandy adds flavor. Heat frying pan with 1 inch of oil. Dip each blossom into the flour and egg mixture, fry, and serve. Good with a green salad.

**Elderflower CLEANSING CREAM** These flowers have an ancient fame for being good for the skin. You can dry them to have year-round. Drop a few in your bathwater or make this special cleansing cream: In a double boiler heat 1 c. homemade buttermilk with 1/4 c. elderberry flowers for half an hour. Remove from heat and let rest for a few hours. Heat again. Strain out the flowers. Add 2 T. honey. Store in a very cool place.

**Elderflower SOOTHING, PROTECTING, HAND AND FACE CREAM** Melt either 1 lb. pure (clarified) lard or the same of petroleum jelly. Then pack in as many elderflowers (stripped from stems) as you can get in and covered. Maintain the flower–lard mix on a very slight heat (don’t boil!) for 60 minutes. Then drain, and rinse in cold water several times. Now crush the berries. Add 3 c. sugar, 1/4 c. lemon juice (or 1/4 c. cider vinegar like the old-timers), and 1/2 t. cinnamon. Cook over low heat, stirring until the sugar dissolves. Then boil hard, stirring constantly, until it arrives at the jellying point. Take off heat. For the next 5 minutes, alternately skim and stir. Have ready clean, hot jars. Ladle your jam into them, and put on lids. Process in a boiling water bath for 5 minutes.

**Jujube**
This fruit tree is hardy in zones 6–10, but it's filed in this book with “Subtropical and Tropical Fruit.”

**Mulberry**
There are many species of mulberry growing around the world. *Morus alba* is a shrubby Chinese variety, 6–8 feet tall, whose leaves are relished by silkworms. Commonly called the “white mulberry” (or often mistakenly called the black), it is common in the South. Its berries can be black or red. *Morus nigra*, the “black mulberry,” is a semi-hardy tree (zones 5–10) that can get 30 feet tall and can survive north to Virginia in the east or Seattle in the west. There are also named varieties that have big, sweet berries in black, red, or white, instead of the rather insipid-tasting old-time tree mulberries. Weeping mulberries are a decorative variety that fruits, but their fruit is of very low quality.

**PLANTING**: Most “mulberry” trees in nurseries are fruitless ornamentals. You can get edible types from Raintree Nursery, Burnt Ridge, or Hidden Springs. Once started, you can grow more trees from cuttings or from seed. Cuttings transplant easily as long as you keep them moist. Nature plants mulberries via the birds. To grow a mulberry orchard as some old-time pig farmers and chicken farmers did as a source of livestock feed, plant them 25–30 feet apart. They'll grow on almost any soil, even gravel or rocks. Mulberries don't need fertilization but will benefit from mulching their first year. Most mulberries are self-fertile. Pests are not a serious problem. Mature plants are able to endure drought quite well.

**Harvesting**: Mulberries resemble blackberries in shape and size and also have many seeds. They're fully ripe when black and soft. The almost-but-not-quite-ripe berries are red and tart and can be used in anything you'll add sugar to. Late June and July are harvest time for birds, beasts, and people. They are less tart and less pleasant-tasting than blackberries, but are healthy to eat. One way to harvest them is to spread a sheet of cloth or plastic underneath the tree, then shake the branches until the fruit falls. Or let the berries fall naturally and gather them regularly. Mulberries stain something fierce. Pros handle them with thin plastic gloves (order through a beauty shop) on their hands. You can use them in the recipes below... or grow silkworms! Silkworms eat mulberry leaves. You can buy silkworm eggs and get info about growing them from Karen Emery, Royal Hare, 707-579-2344; 946 Lodi St., Santa Rosa, CA 95401.

**Preserving**: You'll have to deal with the fruit immediately since it doesn't keep. Make pies or jelly, or freeze.

**Spiced Mulberry Jam** Stem a mixture of ripe and green mulberries until you have a quart. Cover them with cold, salty water (1/4 c. salt per quart of water). Let set 5 minutes. Then drain, and rinse in cold water several times. Now crush the berries. Add 3 c. sugar, 1/4 c. lemon juice (or 1/4 c. cider vinegar like the old-timers), and 1/2 t. cinnamon. Cook over low heat, stirring until the sugar dissolves. Then boil hard, stirring constantly, until it arrives at the jellying point. Take off heat. For the next 5 minutes, alternately skim and stir. Have ready clean, hot jars. Ladle your jam into them, and put on lids. Process in a boiling water bath for 5 minutes.

**Freeze**. Wash and dry the berries, and lay them on a tray for quick freezing. Once hard, move them into freezer containers. If you have both gooseberries and mulberries, try freezing them mixed half and half, unsweetened. They go well together baked in a pie, etc. Or try freezing mulberries with sugar (1/4 c. sugar per 4 c. mulberries).

**Frozen Mulberry Cream** To serve, thaw for almost an hour; then prepare sweetened whipped cream and stir the fruit into it.

**Drying**. Lay mulberries spread thin in a single layer outside on a screen, out of the sunshine, in a warm, dry situation. Don't let birds rob you. It takes 4–5 days to dry them like that—less in a food dryer.

**Nectarines**
See “Peaches.”

**Pawpaws**
This fruit is a North American relative of the South American custard apple (cherimoya). The fruit doesn't survive shipping, so it's not a commercial crop, but for the home gardener this can be a wonderful choice. A deciduous shrub (with leaves up to a foot long), the pawpaw can also be pruned into a single-trunked tree and grow as tall as 20–30 feet high, but it's more naturally inclined to be the sort of plant you'd use as a screen or hedge. They can grow in either
full sun or a somewhat shaded location, and they adapt well to being in the middle of a lawn. Once established they are hardy, usually pest- and disease-free, and expand vigorously.

**CLIMATE:** The wild pawpaw is classified as both a subtropical and temperate-zone plant, for it grows from Florida to Texas and as far north as Michigan. Pawpaws need some winter chilling (they’re hardy to −30°F), prefer hot summers, and are suitable to try in zones 5–9, especially in midwestern areas. They need at least 30 inches of rain per year or the equivalent in irrigation.

**VARIETIES:** There are both inedible and edible varieties, and the edible ones can be hard to find. If the fruit has white flesh it’s a bitter, inedible variety. If the fruit has dark-colored flesh, it’s an edible one. Most “pawpaw” trees sold by regular nurseries are seedlings intended merely to be ornamentals. For your edible pawpaw look for named varieties that are specifically edible.

**PLANTING:** The easiest way to get started is to plant a grafted tree from a nursery. If you’re transplanting a grafted nursery plant, prune back to just a foot beyond the graft point. Pawpaws do best in well-drained, well-mulched, and well-fertilized, deep and slightly acidic loam, but no matter how good your care they tend to be very slow-growing. Keep their soil slightly moist. Growing wild, a pawpaw prefers a fertile bottomland site along a stream or a hillside. You can use the “cuttings” or “layering” methods, or you can try to bring home a wild one by transplanting, but pawpaws are notoriously hard to get started in those ways.

**Transplanting a Wild Pawpaw.** Pawpaws are not easily domesticated. They grow wild but are hard to transplant. There’s a theory that pawpaws need the action of a symbiotic fungus and that you should add soil from near the base of an already established plant to your planting hole. Surely, you should try transplanting only a very young pawpaw, and try to get the entire root system and keep the roots thoroughly moist during transition (and for the first year after the move).

**Pawpaws from Seed.** To use your own seed, keep the seeds damp or else plant them immediately after removing from a fruit. To hold pawpaw seeds indoors over winter, store in a plastic bag in the refrigerator. They are very slow to germinate. Your spring-planted seed may not germinate until mid-summer and may even wait a whole year to come up. An alternative, easier method is to do it nature’s way and plant the entire pawpaw in the fall. Cover the fruit with only a very thin layer of dirt. When the seedlings come up, remove all but the best-looking ones. Exotica carries pawpaw seeds.

**Planting for Pollination.** Pawpaws bear lovely maroon flowers in spring. They blossom early enough that the bees may not be active enough for thorough pollination. Old-time pawpaw lore has it that if you lay a hunk of rotten meat close to the blooming trees, the meat will attract flies that will help pollinate. Pawpaw pollination is rather unpredictable, with some needing cross-pollination and others not. Plant more than 1 tree for best results.

**Pruning.** Once your pawpaw gets going, pruning and cutting off suckers will be necessary every year. If you want a tree, prune away all suckers and lower branches to create a single trunk. If you want a hedge, let the suckers grow that come up in the area where you want the screen to grow; otherwise clip them out. If you have a grafted pawpaw, remove all root suckers, since they’re not the part you want to proliferate. An unpruned pawpaw grows into a dense thicket.

**Harvesting:** In fall your pawpaw crop gradually turns from green to yellow and on to brown (ripe). Harvest when they’re slightly soft. Just exactly when to pick them from the tree depends on how sweet you like them. If you harvest a couple weeks earlier than dead ripe, they will be much less sweet than later, but pleasant in another way. If you leave them on the tree too long, they get mushy and are likely to fall off on their own and be damaged. Look out for late-ripening fruits from late-blooming flowers and leave them on the tree to finish. Handle them gently, and bring them into the house to finish ripening.

**Eating or Preserving:** The flesh of a ripe pawpaw is yellow-orange with a mild banana-like flavor and a custard-like texture. Pawpaws keep only 1 or 2 days. Use pawpaw fruit in a custard pie recipe, make jam or jelly from it, eat it raw, bake it into bread, make dried fruit sections or a leather, or freeze (eat frozen pawpaw immediately after thawing).

**NOTE:** Don’t eat pawpaw seeds. They are classified as “mildly poisonous.”

**Peaches (and Nectarines)**

Peaches and nectarines are my favorite fruits in the world to eat out of hand. I have a little nectarine tree growing in the orchard. Last year a neighbor ran over it with his pickup and practically broke my heart, but one branch survived, and I have hopes for it yet. A nectarine is a variety of smooth-skinned peach. I used to think it was a cross between a peach and a plum, but now I know that’s wrong. Nectarines have existed for centuries and sometimes mysteriously appear growing on a peach tree branch. You can sometimes grow a nectarine from a peach tree seed if that peach has some nectarine in its ancestry and was pollinated by a nectarine.

Peach trees are short-lived, bearing only 10–15 years. If you have trouble growing peaches, try genetic dwarf peaches—they are easiest of all. From California to Georgia, in North and South Carolina, Colorado, Utah, these fruits can grow. They’re a little more tender, though, than apples or pears. They need well-drained soil. Peach leaf curl is a big problem in damp climates.

**VARIETIES:** Peaches were grown in China 4,000 years ago. There are hundreds of varieties. When you choose yours, look for disease-resistant kinds whose climate adaptations are a perfect match for your site, such as the very winter-hardy, spring-frost-resistant, and disease-resistant RedGold nectarine if you live in a chilly place. Among peaches, you can get a very early one, such as Harbinger, or a medium one, such as Red Haven, a late one, such as Lor­ing, or a very late one, such as Stark Autumn Gold—and have peaches constantly coming on from summer through fall. And you can choose between “clingstones” that have a pit to which the peach flesh adheres (best for canning) and “freestones,” easiest to eat raw.

**Pollination:** Peaches bloom early, before their leaves come out, so the crop is always at risk of early frosts. Nec­tarines don’t need a pollinizer, but most peaches do. Consult about pollination needs when you buy.

**Canning Peaches:** Wash them and dip them in boiling water, then quickly into cold water. That loosens the skins so you can slip them off. Now cut the peaches in
halves and take out the pits. If you're slow you can drop the fruit into water containing 2 T. each salt and vinegar per gallon water to prevent darkening. But I just work fast.

**Raw Pack.** Pack your halved peaches into overlapping layers, cut side down, in clean jars. Add hot syrup (or any fruit juice or plain water). Leave ½-inch headspace. Put on lids. Process quarts in a boiling water bath for 30 minutes at altitudes under 1,000 feet, 35 minutes at 1,000–3,000 feet, 40 minutes for 3,000–6,000 feet, or 45 minutes above 6,000 feet. You can process pints 5 minutes less.

**Hot Pack.** Heat the halved fruit in your chosen liquid thoroughly through to boiling. Boil 5 minutes. Then fill hot jars with the hot fruit, and immediately process. Process quarts in a boiling water bath for 25 minutes at altitudes under 1,000 feet, 30 minutes at 1,000–3,000 feet, 35 minutes for 3,000–6,000 feet, 40 minutes above 6,000 feet. You can process pints 5 minutes less.

**CANNING NECTARINES:** Do just as for peaches.

**PEACH KETCHUP** My husband’s favorite. He likes it with game or ham, as a dipping sauce, or in the gravy. Combine 1 qt. stoned, sectioned peaches, 1 chopped onion, 1 c. sugar, ½ c. vinegar, ¼ t. salt, ¼ t. allspice, ½ t. cloves, and ½ t. cinnamon. Boil 1 hour. Fill clean, hot jars. Process in water bath 15 minutes and seal.

**PEACH BUTTER** Scald, peel, stone, and slice 7 lb. of whole peaches. Cook in ½ c. water very slowly until soft—about 3 hours. Then sieve. Add 1½ c. brown sugar.

**PEACH LEATHER** For general instructions about making fruit leather, see Chapter 7. Get the fuzz off the peaches either by washing or peeling. Cinnamon and nutmeg add a nice touch. Peaches are so sweet you certainly don’t need to add any sugar.

**PEACH SAUCE** Use about ½ c. water per 1 lb. peaches. Cook only 5 minutes or so. Optional: add cinnamon and nutmeg.

**PEACH JUICE** Heat the peaches before extracting juice. (But my preference is to can rather than juice peaches because they are the perfect canning fruit.)

**PEACH SPECIAL** Combine half peach juice, half orange or grapefruit juice.

**PEACH SAUCE** Use about ½ c. water per 1 lb. peaches. Cook only 5 minutes or so. Optional: add cinnamon and nutmeg.

**PEACH JUICE** Heat the peaches before extracting juice. (But my preference is to can rather than juice peaches because they are the perfect canning fruit.)

**PEACH SPECIAL** Combine half peach juice, half orange or grapefruit juice.

**PEACH SAUCE** Use about ½ c. water per 1 lb. peaches. Cook only 5 minutes or so. Optional: add cinnamon and nutmeg.

**PEACH JUICE** Heat the peaches before extracting juice. (But my preference is to can rather than juice peaches because they are the perfect canning fruit.)

**PEACH SPECIAL** Combine half peach juice, half orange or grapefruit juice.

**PEACH SAUCE** Use about ½ c. water per 1 lb. peaches. Cook only 5 minutes or so. Optional: add cinnamon and nutmeg.

**PEACH JUICE** Heat the peaches before extracting juice. (But my preference is to can rather than juice peaches because they are the perfect canning fruit.)

**PEACH SPECIAL** Combine half peach juice, half orange or grapefruit juice.

**PEACH SAUCE** Use about ½ c. water per 1 lb. peaches. Cook only 5 minutes or so. Optional: add cinnamon and nutmeg.

**PEACH JUICE** Heat the peaches before extracting juice. (But my preference is to can rather than juice peaches because they are the perfect canning fruit.)

**PEACH SPECIAL** Combine half peach juice, half orange or grapefruit juice.

**PEACH SAUCE** Use about ½ c. water per 1 lb. peaches. Cook only 5 minutes or so. Optional: add cinnamon and nutmeg.

**PEACH JUICE** Heat the peaches before extracting juice. (But my preference is to can rather than juice peaches because they are the perfect canning fruit.)

**PEACH SPECIAL** Combine half peach juice, half orange or grapefruit juice.

**PEACH SAUCE** Use about ½ c. water per 1 lb. peaches. Cook only 5 minutes or so. Optional: add cinnamon and nutmeg.

**PEACH JUICE** Heat the peaches before extracting juice. (But my preference is to can rather than juice peaches because they are the perfect canning fruit.)

**PEACH SPECIAL** Combine half peach juice, half orange or grapefruit juice.

**PEACH SAUCE** Use about ½ c. water per 1 lb. peaches. Cook only 5 minutes or so. Optional: add cinnamon and nutmeg.

**PEACH JUICE** Heat the peaches before extracting juice. (But my preference is to can rather than juice peaches because they are the perfect canning fruit.)

**PEACH SPECIAL** Combine half peach juice, half orange or grapefruit juice.

**PEACH SAUCE** Use about ½ c. water per 1 lb. peaches. Cook only 5 minutes or so. Optional: add cinnamon and nutmeg.

**PEACH JUICE** Heat the peaches before extracting juice. (But my preference is to can rather than juice peaches because they are the perfect canning fruit.)

**PEACH SPECIAL** Combine half peach juice, half orange or grapefruit juice.

**PEACH SAUCE** Use about ½ c. water per 1 lb. peaches. Cook only 5 minutes or so. Optional: add cinnamon and nutmeg.

**PEACH JUICE** Heat the peaches before extracting juice. (But my preference is to can rather than juice peaches because they are the perfect canning fruit.)

**PEACH SPECIAL** Combine half peach juice, half orange or grapefruit juice.

**PEACH SAUCE** Use about ½ c. water per 1 lb. peaches. Cook only 5 minutes or so. Optional: add cinnamon and nutmeg.

**PEACH JUICE** Heat the peaches before extracting juice. (But my preference is to can rather than juice peaches because they are the perfect canning fruit.)

**PEACH SPECIAL** Combine half peach juice, half orange or grapefruit juice.

**PEACH SAUCE** Use about ½ c. water per 1 lb. peaches. Cook only 5 minutes or so. Optional: add cinnamon and nutmeg.

**PEACH JUICE** Heat the peaches before extracting juice. (But my preference is to can rather than juice peaches because they are the perfect canning fruit.)

**PEACH SPECIAL** Combine half peach juice, half orange or grapefruit juice.

**PEACH SAUCE** Use about ½ c. water per 1 lb. peaches. Cook only 5 minutes or so. Optional: add cinnamon and nutmeg.

**PEACH JUICE** Heat the peaches before extracting juice. (But my preference is to can rather than juice peaches because they are the perfect canning fruit.)

**PEACH SPECIAL** Combine half peach juice, half orange or grapefruit juice.

**PEACH SAUCE** Use about ½ c. water per 1 lb. peaches. Cook only 5 minutes or so. Optional: add cinnamon and nutmeg.

**PEACH JUICE** Heat the peaches before extracting juice. (But my preference is to can rather than juice peaches because they are the perfect canning fruit.)

**PEACH SPECIAL** Combine half peach juice, half orange or grapefruit juice.

**PEACH SAUCE** Use about ½ c. water per 1 lb. peaches. Cook only 5 minutes or so. Optional: add cinnamon and nutmeg.

**PEACH JUICE** Heat the peaches before extracting juice. (But my preference is to can rather than juice peaches because they are the perfect canning fruit.)
Harvesting: Pears fruit on long-lived “spurs,” which are short special fruiting branches. Oriental pears, like apples, should be left on the tree until ripe. But common pears are always picked green and stored to ripen. If you leave them on the tree to ripen they tend to go bad at the center or fall off and rot on the ground. Standards produce 3–5 bushels per year, dwarfs less than 1. Pick the pears when they are fully grown but still hard and green—when they change from deep green to pale green and a slight tug will separate them from the tree. Once off the tree, they’ll ripen best at 65°F and 85 percent humidity. Bartlett pears ripen the quickest—in a couple weeks. Keiffer pears are fast, too. Keep below 75°F Oriental pears never get truly soft like the common pear will. When the pears get ripe you need to go ahead and eat them or preserve them some other way.

Preserving

Root Cellar Storage. Pears will not keep in storage unless picked early and stored then! Don’t put any bad ones in the storage box. Box them shallower than deep. It helps to wrap them individually in paper (not newsprint unless you’re going to peel them). Keep them where it’s cool. The ideal is 32–40°F, 80–95 percent humidity. How long they’ll keep depends on the temperature and the variety—maybe 2 or 3 months, maybe even 5. Use up or can up because pears stored overly long won’t ripen normally when taken out.

Drying. Use sweet pears. Wash, peel, and slice them into halves. (Optional peeling method: Boil the fruit until the skins will slip off. Cool. Remove skins.) Scoop out the core with a teaspoon. Lay out the pear halves, or halves cut into slices, on trays or cookie sheets. In oven or dehydrator, dry at 115–140°F with the oven door propped open ¼ inch. Stir or turn once in a while. It takes 12–24 hours, or 2–3 days if drying in the sun. They’re done when they’re leathery and the center isn’t moist (cut to see). Store these dried pears in the refrigerator or freezer.

Stewed Dried Pears. Pour 4 c. boiling water over 2 c. dried pears. Mix in ¼ c. sugar or other sweetening, 4 whole cloves, and 2 t. grated lemon peel. Cook on low heat a half hour. This serves my tribe; divide recipe in half for a smaller family.

Pear Leather. Peel the pears and core them. Don’t sweeten. Use usual leather-making procedures, as explained in Chapter 7.

Canning Pears. It’s best to use them while ripe but still quite firm. Wash, peel, cut into halves lengthwise (or quarters), and core. Work fast or else keep them in a salt–vinegar solution (2 T. salt and 2 T. vinegar per 1 gal. water), and then drain well before canning. Use packing process and times for canned peaches. Add syrup, fruit juice, or plain water (a diabetic friend raves about how delicious his pears are canned in just water!). Optional: add 1 t. lemon juice per quart.

Ginger Pears. To make this “spiced fruit,” peel and quarter 2 lb. hard late pears, removing cores. They shouldn’t be too ripe for best results. Slice thinly. Grate the rind of 1 lemon, and squeeze it to get its juice. Combine lemon juice, lemon rind, ½ c. water, and 2 lb. sugar in a kettle. Add 2 oz. ginger root or crystallized ginger and simmer about 45 minutes, by which time the fruit should be transparent. When the syrup is thick, pour it into jars. Process 10 minutes.

Freezing. Consider first that pears don’t freeze very well. They’re much nicer canned or dried than frozen. Fifty pounds of pears will make about 45 pt. to freeze.

Pear Juice. Follow directions for apple cider under “Making Cider.”

Persimmons

Diospyros varieties grow over a wide range of temperate climate zones and can handle the competition of a lawn. The tallest kinds can get up to 40 feet tall; the shortest are shrub-like. Persimmons are always ornamental, some for extraordinary leaf coloring (Hachiya), and especially in fall and winter, because the brightly colored fruit stays on the tree long after its leaves have dropped. The plant gives a generous harvest, and its wood is valued by carvers. In the western United States, the persimmon is virtually disease- and pest-free. Boreys may go after its trunk in the East, but they can be picked off by hand.

Persimmons are memorably puckering (tannin)—just like biting into a walnut hull, until they ripen; don’t even try it. Then they make a sudden, miraculous transformation, and become the sweetest—and one of the most delicious—of all fruits. Some varieties get sweeter than others; some have more tannin, and hold it longer, than others. When the usual persimmon becomes very soft, the stage at which it becomes edible, it will be very high in sugar content.

Varieties: Worldwide there are hundreds of persimmon species, varying in every conceivable way. Because of great variation in time of fruit ripeness, you can select to have them ripening in succession. There are 2 basic types, American and Oriental. In either case, it is a good-looking deciduous tree.

American. This is a newly domesticated native (Diospyros virginiana), available as a tree or shrub. Its tree form is taller than the Oriental at 30–40 feet. It has a myriad of sub-species varying in size, color of fruit, harvest time, presence/absence of seeds, size, and shape of tree. Its fruits, in general, are smaller, from ½ (wild) to 2½ inches across, and fig-like. It grows suckers that will need to be pruned away regularly unless you want a persimmon thicket.

Oriental. The commercial persimmons (D. kaki) are the result of centuries of careful plant selection. They are always a tree, 25–30 feet tall. Hardy to 0°F they need only 100–200 hours in winter below 45°F to fulfill their genetic chilling requirement and enable fruiting so they do well in southern states. The fruits get large: Fuyu, as wide as 4 inches across and tomato-shaped; Hachiya, 4–5 inches in length. The Fuyu tree is on the small side and is the only type that loses its tanin early enough to be eaten while still crisp, like an apple.

Climate: American persimmons are a little hardier than Orientals, good in zones 5–9, as far north as the Great Lakes and Rhode Island. But persimmons are risky in the more northern areas, because a hard frost that hits before the fruit is ripe can ruin it. In general persimmons can’t survive in the northern plains or northern New England. However, once the fruit is ripe, frost, or even freezing, doesn’t harm it. So the challenge is to find a variety that will ripen before frost hits in your area, as well as a plant that is itself hardy enough to survive your winters. Wild Americans grow in Southern Indiana, Virginia, Alabama, and points between. Orientals are better in hot areas, zones 6–10, for they are only hardly down to around 0°F in the United States,
Persimmons are very sweet! Dry as above. Then chop the dried fruit into slices. Spread them out to dry in a single layer, none touching. Dry at 115°F for 18–36 hours (or 3–5 days in the sun)—until there is no more moisture, even in the center. Your dried persimmons will be brown and chewy, leathery. Turn twice during the drying. You can serve dried persimmons as a candy. Or use them to make a homemade trail mix in combination with other dried fruits, plus some nuts and seeds. Or substitute for “raisins” in any recipe, add to any baked goods, or sprinkle over fruit. Persimmon pulp can be made into a good leather (sieve out the seeds).

**DRIED PERSIMMON “SUGAR”** You can make a pure fruit sugar out of the highest-sugar kinds, which, when dried, are very sweet! Dry as above. Then chop the dried fruit into sections and dry a second time—until very hard. Then blend or grind in a mortar to a powder. That powder is your persimmon sugar. Use it in place of sugar.

**Freezing.** Freezing is suitable for the soft, sweet kinds of persimmons. (The crisp Fuyu that lasts and lasts, is best eaten fresh.) Method 1: A thoroughly ripe, seedless persimmon can be frozen unpeeled and whole. To eat, thaw and spoon out of its skin somewhat like a sherbet. Or peel (the skin will slip if you hold the fruit under running water), dice, and serve with cream. The cream freezes as the fruit.
Plums

These are an easy fruit to grow. My family, though, will ask about 3-4 inches wide. Roll it up in the waxed paper, pint jars only two-thirds full. Can at 15 lb. pressure for square greased baking dish, at 325°F for 1 hour. To can it fill a roll in a 9-inch-square greased baking dish, at 325°F for 1 hour. To can it fill pint jars only two-thirds full. Can at 15 lb. pressure for 25 minutes.

PERSIMMON ROLL CANDY Start with 2 c. fresh or frozen persimmon puree. Mix in 1 c. sugar, 1/2 c. brown sugar, 1 lb. smashed graham crackers, 1 c. chopped nuts, and 1/2 lb. miniature marshmallows. Lay out a sheet of waxed paper and spoon 1/2 of persimmon mixture onto the paper in a roll shape about 3-4 inches wide. Roll it up in the waxed paper, with a sheet of aluminum foil or plastic wrap on top of that, and freeze it. Do the same with the rest of the mixture. To serve, partially thaw a roll, and cut about 8 slices, each of which will be an individual dessert serving. Top the slice with vanilla ice cream or whipped cream.

PERSIMMON FRUIT BARS Combine 1 c. chopped dried persimmon with 1/2 c. of a combination of other chopped, dried fruits (apricots, cherries, peaches, figs, or what have you). Add 1 c. chopped nuts, and 1/2 c. flour that has been thoroughly mixed with 1 t. baking powder and 1/4 t. salt. In another bowl cream together 1/2 c. butter and 1 c. sugar until fluffy. Add 2 eggs and 1 t. vanilla to butter-sugar mix and mix well. Now add the fruit-flour mix to the rest, a cup at a time. Blend thoroughly after each addition (with a spoon, not a mixer). When finished combining, spread it into a greased 9-inch-square pan and bake 45 minutes in a 350°F oven. When done, cool completely before cutting. Slice into 1-inch by 3-inch bars. Roll bars in powdered sugar.

SO WHAT'S A PRUNE? A prune is a kind of European plum, a freestone. It is blue-black and oval, with firm flesh. The sweetest varieties of plums make the best prunes. Blue Stanleys are the usual commercial choice. So, you dry prune kinds of plums and you have prunes. You dry any other kinds and you have dried prunes. There are yet more mysteries to prune production (see "Drying Plums").

Pollination: Japanese plums and European plums won't cross-pollinate. Most European plums are self-fertile. All Japanese plums need cross-pollination, but they are limited to another variety of Japanese plum to do the job. Consult when you buy.

Pruning: Japanese plums need heavy pruning with the strong upper wood whacked back to weaker branches. European plums should not be pruned so severely.

Harvesting: It takes 3-4 years after planting to get your first plum crop. Plums fruit on long-lived spur branches, so don't prune those all away. For bigger plums, you can thin the fruit to 3-4 inches apart, but I don't think it's worth the trouble. Let them ripen on the tree. Pick them when they're soft and they separate easily.

Preserving

Canning. Choose ripe, but still firm plums that are only just beginning to get soft. Among the best varieties to can are Greengages and similarly "meaty" kinds. Wash and drain them. Experienced plum canners prick the skins of the plums a couple times with a fork if they're to be canned whole. That helps prevent the fruit from splitting. Freestones are easily halved and pitted and nice that way.

Hot pack: Add plums to hot syrup and boil 2 minutes. Cover pan and let stand 20-30 minutes. Fill jars with hot plums, cover with cooking syrup. Raw pack: Fill jars with raw plums, packing firmly. Cover with hot syrup. For either hot or raw pack, process in a boiling water bath. At altitudes under 1,000 feet, process pints 20 minutes, quarts for 25; at 1,001-3,000 feet, process pints 25 minutes, quarts for 30; at 3,001-6,000 feet, process pints 30 minutes, quarts for 35; over 6,000 feet, process pints 35 minutes, quarts for 40.

PLUM JUICE Tree-ripened plums of deep color are best. Wash and mash. Simmer until soft in just enough water to cover them. Press and strain. Sweeten if the fruit is tart enough to need it. Can by instructions for apple juice (see "Making Cider").

Freezing. Wash, remove stems and pits, and cut in half. Method 1: Spread out on cookie sheets and freeze like that to get them frozen as quickly as possible. Then move them into freezer bags or boxes, seal, and store in the freezer. To serve the frozen plums, rinse them off and slice them into dishes, letting them defrost enough so you can get your teeth into them. Or eat them whole like fresh fruit. Method 2: Freeze the plum halves in a fruit juice (white grape or apple are good), or syrup, or plain water. These will be best cooked after thawing. Freeze as quickly as possible. Fifty pounds of plums with make about 40 pt. of fruit for your freezer.

Drying Plums. Cut plums in half and remove the pit. Optional: Now blanch the halves by steam for 15 minutes.
Then dry your plum halves (or quarters) the regular way. Some dry them whole, but they're a lot easier to get dry halved than whole. Dry when pliable and leathery. Plums dried without pits are good for pies.

**Dry Prunes.** For results that look somewhat like store prunes, pick the proper variety of fruit when very ripe, and dry it whole. The first secret of prune making is that "very ripe" part. Some expert prune makers even hang a cloth under the tree to catch the plums at that moment of maximum sweetness when they fall from the branch. Another prune secret is to presoak the skin, either by soaking them 20 minutes in very hot water before drying or by soaking them in a lye bath—a solution of 1 oz. lye crystals in 1 gal. water (in a nonmetal container)—for several minutes. Then rinse them well in cool water. Then dry them on trays. To oven-dry prunes, start at 120°F for 15 minutes, and very slowly and gradually increase the heat to 160°F. If you raise the temperature too fast they may burst. Turn them occasionally. It takes about 2 days. A last prune secret is to paint the plums. Let them rest 3 days; then pour off the syrup and dry it whole. The first secret of prune making is that "very ripe" part. Some expert prune makers even hang a cloth under the tree to catch the plums at that moment of maximum sweetness when they fall from the branch.

**Cloning:** In general, quince is hardier than peaches, but also takes longer to get ripe. The principle of rootstock is the same as it is for peaches: root one variety (the quince) on the other variety (a peach). The quince doesn't ripen until 2-3 months after the peach. You can also simply layer the branches and root them in soil. If you plan to put them in the ground in spring and fasten it there somehow. Cover the part that's on the ground with dirt and wait until fall, by which time it will be growing roots. Then cut it off where it connects to the parent plant and transplant to your chosen site.

**Growing:** Quince does best in moist, well-drained soil, but it is quite exceptional among the fruits in that it can endure some wet feet from poor drainage. Prunes fruit best in soil of a medium type rather than either very heavy or very light, and they appreciate full sun. If you want your quince to look like a tree, you'll have to sometimes take out suckers. Prune only in the winter and as little as possible because pruning may result in fire blight. Fertilize only with an occasional mulch or helping of manure because excess nitrogen weakens resistance to fire blight. Quince blooms after apples, in late spring.

**Harvesting:** The fruit is produced on the tips of current growth. It ripens late in October or even November. Don't harvest until they are almost ripe. You can tell because the quinces turn yellow and smell fragrant when they get ripe. They don't drop from the tree just because cold weather arrived, so you've plenty time to get them. Pick somewhat before full maturation, being careful. They seem firm, but quinces actually bruise easily. Store in a single layer and they'll stay good for 2-3 months. If you store quince in the refrigerator or with apples and pears, everything else will end up smelling like quince!

**Cooking:** The reason you've probably never seen a quince is because quinces are sour-tasting and hard, absolutely inedible while still raw. However, when cooked they are good. The Greeks, Romans, and American colonists enjoyed quince dishes: a jelly, or quince blended with other fruit dishes, such as an applesauce made of

---

**Quince**

Quince is an ancient, deciduous fruit, Asian in origin, and a distant relative of the pear. The fruits are yellow, hairy, baseball-sized, and come in several varieties, some round, some pear-shaped, ripening in September. Quince naturally grows as a shrub and makes a good hedge because of thorns and that shrubby style of growth. Or you can prune it (in winter only) to a single trunk and make it grow like a small tree, usually only getting to be about 12 feet tall.

**Climate:** In general, quince is harder than peaches, but a little less hardy than pears. The growing range is wide, from California to the Midwest to the Northeast, zones 5-9. A special cold-zone advantage is quince's blooming time, which is late in spring. In warm, humid areas, quince is more likely to get fire blight and other diseases.

**Varieties:** When ordering plants be sure you get the edible or "orchard" variety (*Cydonia oblonga*). Orange, Pineapple, and Smyrna (probably the best) are good edibles. All quinces are self-pollinating so you need only one. Don't get one of the many ornamental flowering quinces, although they are much harder than the edible. The ornamentals can be deceptive because some produce fruit, but it never ripens and doesn't have the delicious taste, when cooked, of the edible. The fruit of some ornamental quinces will make sauce okay.

**PLANTING:** Use layering, cuttings, or division rather than planting seed, as seedling quinces are unlikely to grow true. To reproduce by layering, simply force a branch down on the ground in spring and fasten it there somehow. Cover the part that's on the ground with dirt and wait until fall, by which time it will be growing roots. Then cut it off where it connects to the parent plant and transplant to your chosen site.

**Growing:** Quince does best in moist, well-drained soil, but it is quite exceptional among the fruits in that it can endure some wet feet from poor drainage. Quinces fruit best in soil of a medium type rather than either very heavy or very light, and they appreciate full sun. If you want your quince to look like a tree, you'll have to sometimes take out suckers. Prune only in the winter and as little as possible because pruning may result in fire blight. Fertilize only with an occasional mulch or helping of manure because excess nitrogen weakens resistance to fire blight. Quince blooms after apples, in late spring.

**Harvesting:** The fruit is produced on the tips of current growth. It ripens late in October or even November. Don't harvest until they are almost ripe. You can tell because the quinces turn yellow and smell fragrant when they get ripe. They don't drop from the tree just because cold weather arrived, so you've plenty time to get them. Pick somewhat before full maturation, being careful. They seem firm, but quinces actually bruise easily. Store in a single layer and they'll stay good for 2-3 months. If you store quince in the refrigerator or with apples and pears, everything else will end up smelling like quince!

**Cooking:** The reason you've probably never seen a quince is because quinces are sour-tasting and hard, absolutely inedible while still raw. However, when cooked they are good. The Greeks, Romans, and American colonists enjoyed quince dishes: a jelly, or quince blended with other fruit dishes, such as an applesauce made of
quince sauce. From Frances Dallosta, Sacramento, CA: “Cut up quince in small chunks, add sugar, cook, and cool. Never let the chunks lose shape and get mushy! It’s like applesauce, just delicious!” Quince mixed with apples or pears also makes a great sauce.

getting quince juice. Cut out the cores and stem and blossom ends (don’t peel) from 3 lb. quinces. Grind the fruit. Combine fruit with 4 1/2 c. water in a nonaluminum pan and heat to boiling, then simmer for quarter hour. Now squeeze out the quince juice in a jelly bag or some such.

quince jelly. Combine 4 c. quince juice, 7/8 c. sugar, and 1/4 c. lemon juice in a pan. Stir together and then heat to boiling. Don’t stop stirring! Now add in 1/2 bottle liquid pectin, and boil as hard as possible another minute—still stirring constantly. Then skim off the foam and pour the jelly into your jars. Cover them immediately with 1/2-inch of hot paraffin. Or make jelly using 2 parts apple juice to 1 part quince, or 1 part cranberry juice, 1 part quince, and 1 part apple juice. Use two-thirds as much sugar as juice. In any case, save the pulp for a quince butter. Or make quince jam.

spiced pickled quinces. Peel about 10 large quinces, cure, and cut them into 1/4-inch sections. Put fruit in a pot. Pour 2 1/2 c. boiling water over it. Cook around 5 minutes. Drain (save the liquid). Measure 1 1/2 c. of the liquid back into the pot. Add about 15 whole cloves, 2 oranges cut into very thin slices, 6 c. sugar, and 2 1/2 c. white vinegar. Boil 10 minutes. Add quinces back in. Boil a half hour more (better stir once in a while). Pour into sterile pint-size canning jars. Process for 15 minutes in a boiling water bath.

quince seed hand lotions. When quince seeds are soaked in warm water they soften and separate into a “goop” and what’s left of the seed. Good, goopy, soothing hand lotions made from this goop were both homemade and commercially produced by the old-timers.

Country poet Dallas A. Sall got this recipe for me from his mother. Soak 2 oz. quince seeds in a pint of warm water for 30 minutes. Strain through a cloth, squeezing well to get the goop off the seeds. To that goop, add 2 oz. bay rum, 2 oz. glycerin, and enough water to make a pint. Add fragrance if you wish.

witch-hazel creme. Sherry McGuanrie of Pouris, Manitoba, Canada, who does chemistry demonstrations, kindly sent me this old-time commercial recipe plus advice that this author should be “editing your Recipe Book to a more manageable size by deleting most of the chatty bits that don’t add to the helpfulness of the text.” So, straight down to business: Soak 4 oz. quince seed in 16 oz. hot water. Dissolve 6 oz. boric acid in 1 28 oz. witch-hazel water. Add 32 oz. glycerin and the witch-hazel water/boric acid solution to the quince seed-water mix. Let that stand for 2 days, stirring occasionally. Then strain and add perfume.

**Subtropical and Tropical Fruits**

That eastern Washington widow Florence Merrifield, who retired in Jalisco, Mexico, keeps sending me tantalizing progress reports: “My banana tree has a bunch of bananas ready and 2 other hands forming. Papayas are getting ripe and some have fallen. And mangos . . . there must have been a ton on the seven large trees in my garden. At last they are all about gone. I also have a large vegetable garden. Some green beans and cukes ready now. Planted 5 more banana trees Saturday . . .”

In general, “southern” or “subtropical” fruits can’t handle freezing or temperatures close to it. Hawaii, southern California, and southern Florida are the most tropical U.S. zones. Northern gardeners can sometimes grow these plants in containers, moving them indoors during cold weather, or in greenhouses, or simply in the house in a sunny window.

**Tropical Fruit Information:** If you can’t grow them, but long to eat organically grown tropical fruits, you can order mangos, bananas, avocados, grapefruit, oranges, and honey from David Starr, a mail-order distributor of organically grown tree-ripened Florida tropical fruits. Free catalog: Starr Organic Produce; 888-262-1242; fax 305-818-6972; PO Box 551745, Ft. Lauderdale, FL 33355; starrorg@msn.com; www.starrorganic.com.

Warm-Climate Gardening, by Barbara Pleasant, covers fruits, vegetables, and herbs for the subtropics. Growing Unusual Fruit, by Alan E. Simmons, covers 100 fruits. Pacific Tree Farms has a terrific book list for subtropical growers, including All About Citrus & Subtropical Fruits, by Moore and Sweet; Fruits of Warm Climates, by Morton; Malaysian Fruits in Colour by Chin and Yong; Manual of Subtropical Fruit, by Papenoe; Tropicales, by Courtright, etc. Florida Gardening: The Newcomer’s Survival Manual is also good. It’s $11.20 from Betty Mackey, publisher, who also offers Herbs and Spices for Florida Gardens ($15.50), and Creating and Planting Garden Troughs: 610-971-9409; PO Box 475, Wayne, PA 19087-0475; bbmackey@prodigy.net.

Join the Rare Fruit Council International for $40 and you’ll get a subscription to Tropical Fruit News, a monthly magazine: PO Box 561914, Miami, FL 33256. Or subscribe to Pacific Horticulture: journal of the Pacific Horticultural Foundation, $25/yr; 510-849-1627; PO Box 680, Berkeley, CA 94701. The High Value Fruit Crop Newsletter, put out by Claude Sweet, offers detailed info on individual exotic food crops, plus a computer system to predict specialty crop profitability for you. Sample $4: RIM Corp., PO Box 370, Carpinteria, CA 93014.

**Avocado:** This is an evergreen tree, 20–40 feet tall in its standard form, 8–10 feet tall as a dwarf. There are 3 basic varieties of avocados. They can be grown in California, Florida, and Hawaii. They need reasonable watering and fertilizing and have a few disease problems. Grafting or budding is far better than planting that big seed. A plant started from the seed will grow foliage, but no fruit.

**Preserving.** You are going to get an abundant harvest of perishable fruit. Eat it, give it, sell it, or make guacamole and freeze it! Or freeze puree for making guacamole later.

**Guacamole**. Peel, remove pit, and mash 4 avocados. Thoroughly mix in 1 chopped tomato, 1/2 t. garlic powder, 1 T. lime juice, plus hot sauce to taste if you’re so inclined (I prefer
it without). This is great in almost any sandwich combination or with chips, in a salad, or as a side dish (without the hot sauce). It can be frozen.

**FROZEN AVOCADO PUREE** Choose avocados that are ripe and soft but have no dark blemished places. Peel, slice into halves lengthwise, discard pits, smash pulp. Option 1: Add ⅛ t. powdered ascorbic acid per quart puree; it will taste and keep better. Option 2: Add 3 T. lemon juice to each quart puree. When thawed, use for sandwich spread, dips, or in salads.

**BANANA:** Bananas have been a domesticated plant for tens of thousands of years. A dried part of banana root that is planted in a warm, moist place will grow again, even after some time. Over the millennia, human selection developed the banana from a fruit with big seeds into a seedless one. Bananas thrive in Central and South America, Pakistan, India, the Philippines, Thailand, and similar climates. Technically, the banana is not a tree. Its trunk is made up not of wood, but of stalks grown up around each other from the roots in a way that forms a hollow tube.

**Planting.** The Banana Tree offers a big selection of bananas, plus brief growing instructions (catalog on Internet): 610-253-9589; fax 610-253-4864; 715 Northampton St., Easton, PA 18042; faban@enter.net; www.banana-tree.com. Bananas are planted with pieces of root. Each banana “root-stalk” has buds that resemble potato eyes. Make sure your piece has a bud. Plant about a foot deep. It will soon send up several shoots. By the time a banana plant is about a foot deep, it will be 15–30 feet tall. Then a purplish flower bud pushes up through the hollow leaf stalk and emerges at the top. It gradually droops and clusters of flowers grow out of it. After the flowers finish blooming and fall off, little fingers of fruit grow from where they were. Each banana is a “finger.” The banana fingers are clustered around the stem in bunches of 10–20, called a “hand.” It takes 3–4 months for the flower bud to evolve from just becoming visible to being a mature bunch of bananas.

**Harvesting.** Pick them green. If bananas are allowed to ripen on the plants, they spoil. Cutting down a banana bunch is a 2-person job. One person, with a knife on the end of a pole, reaches up and partly cuts the stem several feet below the bottom of the hanging banana bunch. The cutter is careful not to cut all the way through because he wants the cut to be just great enough that the weight of the bananas makes them bend over so his partner can just get under them and catch them on his shoulder. Then the cutter trims the stem off the bananas and cuts the “tree” off at the ground. When the bananas have finished growing the plant dies anyway. A banana “tree” will never grow more than just the 1 bunch of bananas. But after the next good rainfall a new banana plant will grow up from the same roots.

**Using.** In food value, bananas are very like potatoes. In tropical countries they are typically steamed, boiled, fried, or baked. For cooking, the firm, green ones are preferred. They are peeled, wrapped in banana leaves, and immersed in a pot of boiling water to boil. When cooked, the fruit may be mashed before serving. To bake, the bananas are chosen green, or slightly ripe, and left in their skins. Or the green bananas may be grated, wrapped in a banana leaf, and baked like that. Or grated green banana is mixed with coconut milk into a paste, and then baked. Bananas are fried plain, or mixed with sugar, flour, and a dash salt, and fried. Or a bread pocket is filled with banana and then fried. Banana “figs” are considered a dessert treat. To make “figs,” ripe bananas are dried in the sun and then sliced. They turn out dark-colored, stock, and sweet. A banana flour is made by grinding dried bananas. The big banana leaves have many uses, too: umbrellas, wrapping “paper,” plates, roof thatching. They can also be made into twine and used to weave mats and baskets.

**Drying.** Perfect bananas for drying are still firm, but flecked on their peels with brown. To prevent darkening, dip sections for drying into pineapple juice (undiluted), ascorbic acid, or a solution of ¼ c. lemon juice in 2 c. water. Method 1: Peel and slice ¼-inch thick onto a drying tray. Method 2: Using a coarse shredder, shred right into your drying pan. Cook 1 minute under the broiler, if you have one. Method 3: Cut in half crosswise, quarter each half and dry.

Spread sections, shreds, or quarters on your drying trays, only 1 layer deep. Dry at 115–125°F in a dehydrator or 140°F in an oven. Turn them over after 3–4 hours, rotate trays occasionally, and stir occasionally. Dry until crisp, about 6–10 hours. Sun-drying bananas takes longer—2 days or more.

**Freezing.** Put ripe fruit through a food mill or mash very thoroughly. Add powdered ascorbic acid or lemon juice to prevent darkening. Freeze. Thaw your puree to use in banana breads or cakes or for baby food.

**BANANA POPSICLES** Linda Crabtree of Kettering, OH, sent me this recipe on February 11, 1976. You'll need firm but ripe bananas and popsicle sticks or popsicle-type sticks; some chilled, strained honey; and chopped salted peanuts. Cut the bananas in half crosswise. Stick a popsicle stick into the end of each banana half as a handle. Coat each one with honey and then roll it in the nuts. Freeze unwrapped until solid.

**BREADFRUIT:** This is the fruit of a very large Polynesian tree Artocarpus. Since its juice hardens on contact with air, natives to the tropics have used breadfruit to waterproof canoes. Breadfruit is similar to chestnuts and potatoes in nutritional value; it provides carbohydrates as well as vitamin C. Just 2 or 3 breadfruit trees can keep a shipwrecked sailor alive.

**Preparing.** Breadfruit is large, as much as 8 inches in diameter, round, with a thick, bumpy outside. **This fruit must be cooked before being eaten.** The fruit’s flesh is an off-white color and tastes honestly like bread. It’s better when prepared on the unripe side rather than being overripe. You can prepare it by boiling it, then mashing and seasoning it with herbs and garnishing it with nut slivers. Or cut it into slices; combine it with sliced onions, carrots, or other vegetables; wrap them in an edible leaf; and barbecue it. Or steam breadfruit until cooked, then scoop the flesh out of the rind, mix it with pineapple chunks, flavor it with molasses, and serve with baked squash. Or cut the breadfruit center into chunks and stuff a bird with it and roast them together. Or boil the fruit, then serve with a pasta sauce. Or bake the fruit until very well done, then serve it with an herb butter.

**CACTUS:** See “Prickly Pear.”

**CAROBOLIA:** The carobola tree (Averrhoa carambola) will grow only in southern Florida, Hawaii, and points south. The leaves are sensitive and fold up when touched. It
blooms pink flowers, 3 sets a year: spring, summer, and fall. You can choose between a sweet-fruit or a sour-fruit kind. Or try *Avverhoa bilimbi*, the "cucumber tree." It's closely related and similar in needs to carambola, though even less hardy.

**Planting.** Pacific Tree Farms carries it. You can grow these from seed. Graft good scions to seedlings if you want more control of fruit type. Baby trees are more vulnerable to cold than their elders, which can live at temperatures down to 28°F—provided it doesn't stay there very long.

**Harvesting.** The carambola fruits are the size of a large orange, good-tasting, and good for juicing.

**CAROB:** The carob tree (*Ceratonia siliqua*) is an evergreen leguminous tree that grows 20-40 feet high. Carob is a prized shade tree, windbreak, or screen plant because of its dense foliage. Carobs can't live where temperatures get lower than 20°F. They also don't appreciate high-precipitation climates. They are perfect for mild-wintered southwestern areas as long as they are away from the coast.

**Planting.** Carob is easy to grow. If you don't have a full-sun site for it, plant where there's light shade, and it will get along. Carob can be started from seed or by budding, but carob seedlings are unpredictable in their fruiting performance. Many trees offered in nurseries are seedlings intended only for ornamentals with no attention to fruiting and no identification of gender. You can get carob seed from Exotica or from Redwood City. Starts are available from Exotica. Dwight Roberts (3111 Victoria Dr., Alpine, CA 91901-3679) will swap carob seed for your regional seed. He also has acacia, loquat, and yucca seed. There are some named varieties, some immune to worms.

**Pollination.** A few varieties are self-fruitful, but most carobs are not, and you need at least 1 male and 1 female tree to get fruit. It's safest to plant at least 5 if you're growing them from seed because you need good odds to get at least 1 of each sex. You won't know what sex they are until after 3 or maybe even 5 years.

**Growing.** Carob gets along in any well-drained dirt—sand or clay being equally acceptable. They don't need fertilizing. The mature tree doesn't need watering although some watering will increase your carob bean harvest. Carob can be allowed to grow its natural way into a multi-stemmed shrub or pruned to be a tree (but prune as little as possible). With no pruning it will eventually get about 40 feet high and 40 feet wide. Carob roots are extraordinarily efficient at finding their own water so this plant is a natural for desert homes.

**Harvesting.** The flat, long (about 10-inch), edible "bean" pods ripen during October and November. When they have turned dark brown, they are ready for harvest. You can eat them right off the tree out-of-hand. If you have a problem with moldy or wormy pods, it means there was too much rain during the pod-ripening time. To deal with the worms, you must pick up and somehow destroy every ground-scattered pod. Carob beans can be fed whole to any of your livestock and will delight them.

**Making Carob Powder.** You'll find carob pods sweet-tasting and chewy, resembling a date. They contain little black seeds. Commercially, the pods are roasted and then ground to create carob powder, a healthy chocolate substitute. But that kind of processing simply is not possible at the household level. If you want to try making a powder of them, first wash the pods, then pressure-cook 20 minutes at 15 lb. The purpose of the cooking is to soften those pods enough that you can split them open to get the seeds out fairly easily. After the seeds are removed, chop pods into pieces, and put them through a drying process. Once they are good and dry, grind into a powder in a blender or with a mortar and pestle. You'll be able to process only a little at a time. Use your powder in general as a chocolate substitute.

**Cherimoya:** *Annona cherimoya* is a small tree from the American tropics. Called "cherimoya" or "cherimoyer," it will grow in the south of California and Florida. The fruits are egg-shaped and can weigh more than a pound. The texture is smooth and the flavor is a combination of peach, pineapple, and banana. The tree grows quickly and fruits after only 2 years, but the flowers have to be hand-pollinated (use a paintbrush) in order to get fruit from the flowers. This fruit is delicious fresh and not preserved.

**Varieties.** The custard apple (*Annona reticulata*) is closely related to cherimoya. These trees are deciduous, frost-tender, and grow up to 20 feet tall. The fruit ripens in late winter. You can plant from seed. Custard apple makes good rootstocks from grafts of cherimoya, soursoap, and sweetsop. Its fruit is terribly sweet, best when eaten chilled. Sugar apple is another related variety. They all need high humidity, well-drained soil, and neither too much cold nor too much heat.

**Citrus:** For more information, read *Citrus—How to Select, Grow, and Enjoy* (Tucson, AZ: H.P. Books, 1980)—very thorough. A Red Flame grapefruit tree can live to be at least 40 years old!

**Citron.** There is a "citron" fruit that looks like a large lemon and grows on a small shrubby citrus tree (*Citrus medica*). The preserved rind is used to flavor cakes and puddings. (Don't confuse with the "citron" that is a small hard-fleshed watermelon variety that is made into pickles and preserves.)

**Citrus Juice.** Tree-ripened citrus fruit (oranges, grapefruits, lemons, limes), if you can get it, makes the best juice. Don't heat citrus juice and don't strain it. Just halve your fruit and extract the juice on a juicer or what-have-you. Don't press the oil from the rind, and do remove the seeds. Don't sweeten the juice unless it is for lemonade and limeade. I've heard that navel oranges don't make good juice for canning or bottling but I don't know why. Cut away the navel ends before you juice them. If you want to strain the juice use something with big holes. To get the maximum juice from the fruit, quickly heat it in hot water for several minutes before squeezing or roll it to soften.

**Juicing Oranges.** You can figure that a dozen large oranges will give you 7 or 8 (8-oz.) glasses of juice. A dozen medium-sized ones would give you 6 or more glasses, and a dozen small ones would give you 4½-5 glasses. It's a good idea to work as rapidly as possible to preserve nutritive values.

**Limes.** These are more acidic than lemons. They can be substituted in almost any recipe calling for lemons, using two-thirds as much lime juice as lemon juice.

**Citrus Combo** Two-thirds grapefruit or orange juice combined with one-third other juice: it can be apricot, peach, nectarine juice or purees, or any other juice you want to experiment with.

**Grapefruit-Grave.** Combine half grapefruit juice and half grape juice. Serve over ice cubes.
**ORANGEADE** Combine 2 T. sugar or other sweetener, 1 c. water, and the grated rind of 1 orange in a saucepan. Boil 5 minutes. Cool. Add 2 c. orange juice and 2 c. cold water. Serve chilled over ice.

**LEMONADE** For each serving mix 4 T. lemon juice, 2 T. sugar or other sweetener, and 1 T. ice water. For a batch, juice 5 lemons. Add 5 c. water and sweeten to taste. Serve with a slice of lemon in each glass.

**PINK LEMONADE** Add to a pint of lemonade prepared in the usual way, 1 c. or less of strawberry, red raspberry, currant, or cranberry juice. (A little cranberry juice goes a long way.)

**LIMEADE** For each glass use 3 T. lime juice, fill with water, and sweeten to taste. Serve with a slice of the lime in each glass.

**ORANGE SYRUP** Strain the juice of 24 oranges and 6 lemons. For each pint of juice add 1 1/4 c. sugar. Boil the juice-sugar mixture, skim, strain and chill.

**IRENE’S LEMONADE SYRUP** Combine 2 c. sugar, 1 c. water, and 2 lemon peels cut into small pieces. Boil 5 minutes. Add the juice of 6 lemons. You can either strain the syrup or just leave the cooked peel in it. Keep it refrigerated.

**ORANGE FLOWER WATER** Combine 1 lb. orange flowers and 1 oz. grated orange peel (no white pulp) with 4 c. water. Let soak 24 hours. Concentrate to 2 cups. Or dissolve 1 oz. orange essence from an herbal supplier in 1 gal. distilled water.

**SIMPLE ORANGE MARMALADE** Cut 6 oranges into quarters and then cut each quarter into thin slices. Discard the seeds. Measure your resulting fruit and then add 3 c. water per cup fruit and let soak overnight. The next day simmer until the rind is tender. Then add 1 c. sugar for each cup of fruit. Cook until fruit is clear and the syrup sheets from a spoon (222°F). Pour into glasses and seal.

**Rinds.** If your rinds are unparaffined save a reasonable amount, grate, and store tightly covered in the refrigerator for appropriate dishes. It's called “zest.” Don't include the white inner pulp!

**COCONUT:** See “Nuts.”

**DATES:** The date palm is one of the oldest food-bearing trees to have been cultivated and also is one of the most useful. Dates grow on a palm with feathery foliage that light passes through easily, so beneath the branches of a 100-foot palm there is enough sun to support another layer of plants. Cultivating a date palm takes a lot of effort, but dates are so healthy and delicious that it's worth it. Date palms are very pestilence problems. Once established, fig trees are long-lived.

**Fig; otherwise the Smyrnas won't get pollinated and their fruits won't mature.** Smyrnas figs are large and delicious, and they dry well (they're familiar commercial dried figs).

**Others.** Dwarf figs are sold in tubs from nurseries. This is one of the best varieties for container planting. Kadota figs are the best to can. Mission and Kassaba figs dry well. Turkey figs are good eaten fresh off the tree.

**Planting.** Don't start from seed; you may get a plant, but you're taking a chance on its fruiting capacity. Propagate by budtings, cuttings, grafting, or layering.

**Planting from a Cutting.** Cut off a 10-24-inch length of previous season's growth. Don't cut it off until the fig is thoroughly dormant, its leaves all dropped. Bury the cutting in sand and store it in a cool place for the winter. In the spring, plant the cutting half underground and half above, in well-drained soil of any type in the place you intend for its permanent home, since transplanting is risky. Plant it where it can get plenty of sun, since less light results in less fruit.

**Planting in a Container.** Start your cutting in a 4-inch pot. When the roots have filled that size, move the plant to a 6-inch one. But if you started your fig in the garden in the spring, but want to shift it to a container in the fall for safety, it will need a still larger pot or a small “tub.”

A wonderful thing about figs in pots is that when winter comes you can simply take them inside and store them until spring. They'll be fine in a cellar, or a basement. To winter

The fig family is a large one, and the different types of fig can be extremely unlike. Not all are even edible. Pollination is totally different and sometimes very complex and difficult, depending on the variety. Some figs are self-fertile, some are not. Plants are available from Burnt Ridge. The California Fig Advisory Board offers lots more info: 559-224-3447; 800-588-2344; fax 559-244-3449; 3425 N. First St., Ste. 109, Fresno, CA 93726-6819; info@californiafigs.com; www.calfreshfigs.com.
June to November. Leave figs on the tree until they're just appears along the branches; that's because the fruit act-sweetened, simply stacked in your container or with wa-pack covered with a light syrup with ascorbic acid added. Leave head space. Or put fully ripe figs into food-grade hours for whole figs, 12 hours for pieces. To store dried small pieces. In a dehydrator or oven, dry at 120°F, 36-48 minutes or dip them into boiling water for just 30 seconds. Drain and dry For quickest drying, poke holes in each fig and cut off the stem and blossom ends. Steam them for 20 minutes and bring to a boil. Let rest a few minutes. Pack into jars acid anyway. Wash thoroughly. Drain. Do not peel or re-move stems. Hot pack only. Cover figs with water or syrup and bring to a boil. Let rest a few minutes. Pack into jars hot. Add 2 T. bottled lemon juice per quart, or 1 T. per pint to the jars. Cover as needed with more hot water or syrup. Leave ¼-inch head space. Adjust the lid. Fill jars with hot figs and cooking syrup. Process in boiling water bath: At altitudes to 1,000 feet, process pints 45 minutes, quarts 50 minutes; at 1,001-3,000 feet, process pints 50 minutes, quarts 55 minutes; at 3,001-6,000 feet, process pints 55 minutes, quarts 60 minutes; above 6,000 feet, process pints 60 minutes, quarts 65 minutes.

**BAKED FRESH FIGS.** Wash about 2 dozen large figs and cut off both ends. Set them in a glass baking pan and pour a nice fruit juice over the top——apple is best. While they are baking (in a moderate oven) stir the juice every once in a while to moisten the figs and roll them over occasionally. Cook them at least 40 minutes. Good with whipped cream.

**SPECIAL FIGS.** Put in the oven as for baked figs (350°F) with the contents of a 16-ounce can apple juice concentrate. After 40 minutes, turn the heat down to 150°F and dry them for 30 minutes more. They come out "candied."

**GUAVA:** This tropical American native, *Psidium guajava*, a.k.a. the "Florida peach," is an evergreen shrub or small multi-stemmed tree (about 20 feet high) that is now grown in subtropical and tropical areas all over the world. To grow guava you need a frost-free zone and warm weather. The fruit has a strong smell that some people don't like. Guavas easily freeze out, but then resprout from the old roots and will be fruiting again in a few years. These trees handle soils that are unusually acid or alkaline but need lots of fertilizer.

**Varieties.** The common guava belongs to the Myrtle family. For eating out-of-hand, people prefer the uncommon guavas such as the "white" guavas, popular in California and Florida. And there are others.

**Strawberry Guava.** This close relative, *P. cattleianum*, a.k.a. "Cattley guava," has round, purplish-red, 1-inch-long fruit. It actually does taste like a strawberry. This one is a little harder than the common guava and, once fully grown, can survive down to 22°F for a bit.

**Pineapple Guava.** *Feijoa sellowiana* is another close relative with similar characteristics—hardy to 15-20°F—but it prefers a cool summer and won't set fruit in a desert, or in the deep south of Florida. It does tolerate some salt in the soil, is disease-resistant, and thrives wild in Hawaii. Pineapple guava is exceptionally good eaten raw. Let it get entirely ripe though; the flavor improves much with the final ripening. The basic rule is that they aren't completely ripe until they actually fall off the tree. To serve, cut in half and spoon the fruit flesh out of the skin like you do a cantaloupe. Good in any fruit mixture.

**Planting and Growing.** Modern orchard guava trees are the result of extensive selection for commercial quality. Make
sure you start with a type bred for good fruiting rather than ornamental talents. Don't plant from seed; they will grow but you could end up with anything. (If you must plant seeds, plant straight from the fruit into your planting site; germination will be in a few weeks.) Plant just before your rainiest season. Most varieties are self-pollinating, but a few are not. Find out when you buy. Guavas do best in deep sandy loam and need good drainage. You can propagate by layering, root cuttings, or grafting. Full sun or partial shade is okay. Pinch to thin. Guavas start to fruit as soon as 2 years after planting. Starting then, fertilize with organic manure or compost 4 or 5 times a year, as long as fruiting continues, and it may do so year around. Weeding is best done by mulching. Winter pruning of old branches will stimulate fruiting. If you have a dry season, you'll have to irrigate then.

**Harvesting and Using.** Guava fruits are a true berry, and the tree bears a lot of them. The shape of the fruit varies with variety from round to pear-like; size varies from walnut- to apple-size. Harvest season is about a month and a half in the summer. Unripe guavas are literally green. As they ripen they turn yellow, perhaps with some red. Inside the thick outer skin, the pulp contains many seeds. Fresh guava has a musky quality, but improves greatly when cooked. Guava fruit can be eaten fresh—they're rich in minerals and vitamins, especially C, but they are more often used to make jelly (guavas are high in pectin) or conserve.

**Freezing.** Peel the fruit, cut off the portion between the peel and the seeds. Freeze that.

**Jujubes:** The jujube is an Asian fruit tree with weeping-willow-type drooping branches. They are thorny, beautiful plants with shiny deep-green leaves.

**Climate.** Jujubes are very hardy trees that will survive in almost any climate (zones 6 to 10), but they require long hot summers to bear fruit and cannot do without full sun. They also like dryness.

**Varieties.** There are both shrub-like and tree varieties—15–30 feet tall—and both evergreen and deciduous varieties. But the Lang and Li varieties are the only 2 kinds of jujubes generally available in the United States, though the Mu Shing Hong and Sui Mon can sometimes be found, too. These are all Chinese jujubes, deciduous trees with clumps of thorns. There are also, if you look hard enough, Indian or Malay jujubes (Ziziphus mauritiana). They are evergreen trees with broad thorns along the undersides of their branches; they are harder plants with a smaller fruit than the Chinese jujubes. They need cross-pollination, so plant 2 different varieties. Jujube starters can be difficult to find, but Pacific Tree Farms lists both Chinese and Indian/Malay varieties in its catalog.

**Planting.** These can be planted from seeds or propagated by grafting. Jujubes do best in high-quality, well-drained soil, but will make do with almost anything. They don't require fertilizing or special care, and are resistant to most diseases, although in very wet climates they may catch funguses. They have suckers that can break through pavement, though. To discourage those powerful wandering roots, water the plants infrequently and deeply.

**Harvesting.** The fruit is harvested in the fall. Jujubes are shaped like huge roundish olives, reddish-brown in color, and crisp to bite into and mild when just coming ripe, but softer and much sweeter when dead ripe.

**Drying.** Jujubes can be eaten fresh, dried, or candied. For drying, harvest very ripe, riper than you would usually eat them fresh. Dried jujubes resemble dates in taste.

**Loquats:** This fruit, also known as "Japanese medlar," Eriobotrya japonica, grows on an evergreen tree. Some people like the taste, some don't. They do well on a beach and near the ocean, full sun to some shade. "Champagne" has a big fruit with the best flavor. The leaves are large. Loquat is an evergreen of the rose family! The fruit is juicy with an acid-sweet flavor and yellow flesh, and it contains a few dark seeds—sort of like eating super-sized rose hips.

**Climate.** Loquats come from southeastern China and are grown in quantity in Japan and Taiwan. There are loquat orchards in California and some grown also in Florida. They're semi-hardy, okay down to 15–20°F, but the fruit crop is ruined by a freeze so they do best in California or the Gulf states. Loquats are harmed if the temperature falls below 32°F Loquats grow 15–25 feet tall where it's warm and wet, 20–40 feet under the best conditions, shorter than 15 under least favorable conditions. They can handle drought once well-started, but you won't get much of a fruit crop unless you water.

**Planting.** Make sure you get a grafted, named variety, not an ornamental whose fruits would not be as good. But most nurseries just have seedlings rather than the grafteds. You need only one; they're self-pollinating. Plant them where the drainage is good because they can't handle wet feet. They do best in gravelly loam or clay on slopes. If you prune, a modified vase form or hollow round headed form is traditional. This tree can get fire blight. Organic manures are considered essential for a good crop in the Orient, applied at a very young stage of the fruit and again after harvesting. Flowers and fruits are both thinned. You can do your own propagation by aerial layering.

**Harvesting.** Loquat flowers appear in September and October. The fruit ripens from January to April of the following year, depending on your variety. The variety called "Early Red" is ready to eat in January. "Advance" ripens March to May. (Loquats are the earliest fruiting fruit in their areas.) The fruits are small, loosely clustered, and yellow. They have top flavor when fully ripe but make better jelly and preserves when somewhat on the green side. They're ripe when fully colored and somewhat soft.

**Canned Loquats** Remove stem and blossom ends. Cut fruit in half and take out seeds. Cook about 5 minutes in water or syrup. Pack hot. Cover with the hot liquid you cooked them in. Leave %-inch head space. Put on lids. Process pints 15 minutes, quarts 20 minutes in a boiling water bath.

**Loquat Jelly** Remove blossom ends from about 10 lb. loquat fruit and cut fruit in half. Add 2 c. water and 1 c. lemon juice. Simmer until tender. Strain and measure juice. Add ½ c. more lemon juice. Boil juice 5 minutes, then add 5 c. sugar. Cook until jelly test works, or add 1 package powdered pectin. Then pour into jars, adjust lids, and process in a water bath for 5 minutes.

**Tropical Fruit Cup** Mix ½ c. sugar and 1 c. water, boil 5 minutes, chill, and add ¼ c. lemon juice. Gently mix 3 peeled, sliced kiwi fruits; 3 peeled, sectioned sweet citrus fruits; and 3 c. fresh, sliced loquats (or 1 c. canned). Pour syrup over fruit. Chill and serve. Fancy: Add some sliced ginger root to syrup before boiling. Remove the ginger before adding fruit.
The Olive Climate

1. Zones 9–10. (See the planting zone map in Chapter 2.)
2. No spring or summer temperatures of 28°F or lower. Those damage blossoms and fruit.
3. Preferably no temperatures below 15°F; those damage the tree itself. At 10°F or below the tree will die.
4. Altitude not above 2,000 feet.
5. Winter is cool enough that there are at least 2 months of chilling when temperatures average 50°F.
6. Pollination doesn't go well in high humidity.
7. A long summer with high heat is needed for fruit to mature.
8. The tree can handle drought (8–10 inches water per year), but will fruit better with deep watering once during blooming and once again in early fruiting. Its long taproot is made to pull up water from the water table. Too much rain and humidity above ground makes it more disease-prone.

Lychee Nuts: The following was written by my son Jacob at age 16: "My mother spent a year and a half in Taiwan (although it seemed like forever), and according to her, lychee nuts were one of the best features of her stay. However, my friend Rosal described them as being 'Disgusting. Like a grape, except really gross,' so it would be best to be sure that you like the fruit before you commit yourself to growing it. Lychee nuts can be found canned or dried in Chinese specialty stores and in many supermarkets. The trees are tall, beautiful, rounded evergreens and are practically free from care. They originate in southern China and the fruit is shaped like an eyeball with a pebbled, paper-thin shell and a grapelike flavor. To preserve, dry or make into preserves."

Growing. The lychee nut will grow only in areas with cool, dry winters and cannot withstand extremes of temperature. In the United States it's grown in Southern California and Florida. It will grow easily in loamy, fertile soil, especially if it is given compost or manure in early spring. It has almost no problems with insects or diseases, though you may wish to spray it with Malathion if it becomes infested with aphids.

Planting. The lychee nut can be planted from seed, air layer, cuttings in sand, or grafting. Air layers work best because the plants reach maturity much more quickly. Transplanting is best done in winter, though you can get away with it in any season.

Varieties. There are a number of Taiwanese varieties, the most popular of them being "Black-Leaf." None of them vary widely from each other. But you may wish to consider the Longan, which is a close relative of the lychee nut. Its skin is yellowish-brown rather than red, and it is a hardier, shorter (35 feet) tree—those are the only real differences.

Mesquite. This multiple-trunked desert native, Prosopis fuliflora, is a nitrogen-fixing legume, a distant relative of carob, and is amazingly well-adapted to desert survival. The long, sugar-rich bean pods provide a food both humans and animals can eat. Stock also enjoys munching on young mesquite. Mesquite roots go amazingly deep and far and are a good source of wood in the desert.

MESQUITE (OR CAROB) BEAN DRINK Soak the seeds in water for several hours to get a sweet lemon-flavored drink. Or grind the seeds and mix that powder with water to get your beverage.

Olives: The mango and Olea europaea, the olive, are the most long-lived of domesticated fruit trees. They both can live to 600 years! Despite its age, an olive grows only 15–35 feet high. It's an evergreen with pretty silvery leaves and abundant, fragrant flowers in May and June.

Climate. Olives will grow in the interior valleys of California, southern Arizona, New Mexico, and Texas.

Planting and Growing. Olives need good drainage and fairly fertile soil (not very alkaline!), and full sun. Give the tree about 30 square feet of its own. The fruit drop is messy so the trees are best situated over a lawn or other ground cover or mulched ground rather than a patio, walkway, or driveway. These are the kinds in order of size of fruit, smallest to biggest: Sevillano, Manzanillo, and Mission.

Buy a fruiting, rather than ornamental, variety. Ornamentals do not fruit, but not nearly as much.

Most, but not all, olives are self-fertile, but cross-pollination gives you more fruit. They tend to bear every other year, so plant more than one. Plant bare-root nursery trees in winter months only. This tree has a long taproot. Coat or paint trunks of your newly planted olive to protect it from sunburn. Keep strawberries away from your trees since they may carry verticillium wilt, a risk for olives. Don't fertilize until fruiting starts, and if then not much.

Olives will grow from ripe (black olive) seeds if you chill the seeds first (3 weeks in the ice-cube tray freezer), but seedlings are genetically unpredictable. So plant from cuttings: just cut off and stick in the ground. Or graft cuttings onto seedling roots.

Olives naturally drop their leaves every 2 or 3 years, in the spring.

Harvesting. The tree takes 4 years to bear. The fruit develops on new wood from the previous year's growth. Thinning gives you larger fruit. Olives are easy to grow but the harvesting and curing is work. Don't harvest olives from public ornamental plants unless you're sure pesticides and herbicides haven't been applied. Olives are first light green, a pale straw color, or rosy red. When fully ripe they're black. Pick green for a "green-ripe" curing. Pick reddish-black for a Greek cure. Pick fruit for curing off the trees gently so it isn't bruised or skinned. You can hold the olives for curing in a salt brine (¾ c. salt per 1 gal. water) in a cool place for just a few days. But if you haven't started curing by then, they'll be too soft. To harvest olives for oil pressing you can leave them on the tree as long as desired, and hit the branches to bring them down onto tarps or plastic you've spread under the tree.

Curing Olives. You can't eat olives straight off the tree. When fresh they're loaded with tannin and, so, very bitter. They have to be "cured" before eating. Lye neutralizes the acid as part of one curing process, but that lye is even more of a risk to you than uncured olives so be very careful when using it.
Be extremely careful when working with lye. If lye comes in contact with human skin, it causes a chemical burn. Flush immediately with water. If it is not flushed, it will continue to burn. If possible, add a little salt to the water. If water is not available, use soda water or soda pop—they're better than nothing. If after 5 to 10 minutes your skin is still red and painful, seek burn care in a hospital emergency room.

If lye is swallowed, call 911. Swallowing lye can be fatal. When swallowed, it burns the esophagus, so vomiting (which may be inevitable) should be avoided. Take milk or ice cream to help neutralize the lye's chemical reaction. Although vinegar, orange juice, and so forth also neutralize lye, they should not be ingested because the combination creates heat. This rise in temperature will burn physically in addition to the chemical burn.

If lye gets into the eye, call 911. Flush the eye immediately with water; add salt to the water if possible. Again, use milk if available, to neutralize the chemical reaction. Most likely you should get to an emergency room as soon as possible. Do not use vinegar or boric acid solution.

But the best advice is: Be Careful!

**ANTIDOTES FOR LYE BURNS**

1. Prepare a solution of 2 oz. (about 4 T.) of lye to each gallon of water. (An easy way to do this is to dissolve a 12-oz. can of flake lye—household lye—in 6 gal. water.) Use a wooden, glass, heavy plastic, or stoneware container. Never use an aluminum container because the zinc will dissolve and may make the olives poisonous. Stir the solution until the lye is well-dissolved. Then let the solution cool to a maximum of 65-70°F.

2. Cover the olives with the lye solution early in the morning. Place a towel or cloth over them and push it down tightly to keep the olives submerged. Stir the olives with a lath or a wooden or stainless steel spoon every 2 or 3 hours until the lye reaches the pits. This usually takes 10-12 hours. You can judge the amount of penetration by cutting sample olives to the pit with a sharp knife at intervals of 1 or 2 hours. The lye solution discolors the flesh to a yellowish-green color. Test the biggest ones. The olive's inside will be a yellowish-green color where the lye has penetrated, but it's hard to see the line of separation between that which has been penetrated and that which has not. Keep an uncured olive handy to compare colors. How long it takes the lye to reach the pit depends in part on the weather and the temperature. It can be from 8 to 48 hours.

If the lye has not reached the pits by bedtime, remove the lye solution and cover the olives with water. The reason for such caution is that if the lye gets into the olive pits, it's next to impossible to get it out again. Next morning, pour off the water and cover the olives with a solution of 1 oz. (about 2 level T.) of lye per 1 gal. water and let stand until the lye reaches the pits completely. This may take as long as 30 hours if the fruit is quite green.

Frequently, this lye treatment is insufficient. Some olives neutralize most of the lye so that it fails to penetrate to the pits. In such cases, prepare a fresh solution of 1 1/2 oz. (3 level T.) of lye per 1 gal. water and allow it to cool. Then discard the used solution and pour in the fresh. Let the olives stand until the solution reaches the pits, then follow the procedure in steps 3 to 5.

3. Pour the lye solution off the olives and throw it away. After the lye stage, you have a long rinsing stage. Then comes the brining period. And then you eat or can them.

4. Rinse the olives twice in cold water, then cover them with cold water. Change the water 4 times each day until you can no longer taste the lye in the olives. This may take as long as 7 or 8 days. (For commercial packers, it takes about 4 days.) EXPOSE THE OLIVES TO THE AIR AS LITTLE AS POSSIBLE DURING THE LYE TREATMENT OR THIS RINSING.

5. Prepare a salt brine containing 4 oz. (about 6 1/2 level T.) of salt per gallon of water. (If the solution seems too salty, reduce the amount of salt to 3 3/4 oz.) Dissolve the salt thoroughly, and cover the olives with the solution. Let stand for 2 days.

The olives are now ready to use. Store them in a cold place, preferably in a refrigerator. They are susceptible to spoilage. Refrigerate and use within a short period of time (2 weeks). Or you can make them last longer by brining.

6. If you do not plan to use the olives within 2 weeks, prepare a brine using 8 oz. (about 13 level T. or slightly more than ¾ c.) of salt per gallon of water. Store the olives in this brine for 1 week. Then replace the brine with a solution of 1 lb. (26 level T. or about 1 ½ c.) salt per gallon of water. After 10-12 days, put the olives in a fresh brine of 1 lb. of salt per gallon of water. In this strong brine, it may be 2 months before your olives begin to deteriorate.

---

**Green-Ripe Cured Olives.** These instructions are from the University of California, Agricultural Sciences Department.

This process will produce straw-yellow to green or brown olives. Choose fruit that is green, straw-colored, or cherry-red. Do not use black-ripe fruit because it is likely to become soft when pickled. **Start early in the morning. This is going to be a 12-hour work day.**

- **1.** Prepare a solution of 2 oz. (about 4 T.) of lye to each gallon of water. (An easy way to do this is to dissolve a 12-oz. can of flake lye—household lye—in 6 gal. water.) Use a wooden, glass, heavy plastic, or stoneware container. Never use an aluminum container because the zinc will dissolve and may make the olives poisonous. Stir the solution until the lye is well-dissolved. Then let the solution cool to a maximum of 65-70°F.

- **2.** Cover the olives with the lye solution early in the morning. Place a towel or cloth over them and push it down tightly to keep the olives submerged. Stir the olives with a lath or a wooden or stainless steel spoon every 2 or 3 hours until the lye reaches the pits. This usually takes 10-12 hours. You can judge the amount of penetration by cutting sample olives to the pit with a sharp knife at intervals of 1 or 2 hours. The lye solution discolors the flesh to a yellowish-green color. Test the biggest ones. The olive's inside will be a yellowish-green color where the lye has penetrated, but it's hard to see the line of separation between that which has been penetrated and that which has not. Keep an uncured olive handy to compare colors. How long it takes the lye to reach the pit depends in part on the weather and the temperature. It can be from 8 to 48 hours.

If the lye has not reached the pits by bedtime, remove the lye solution and cover the olives with water. The reason for such caution is that if the lye gets into the olive pits, it's next to impossible to get it out again. Next morning, pour off the water and cover the olives with a solution of 1 oz. (about 2 level T.) of lye per 1 gal. water and let stand until the lye reaches the pits completely. This may take as long as 30 hours if the fruit is quite green.

Frequently, this lye treatment is insufficient. Some olives neutralize most of the lye so that it fails to penetrate to the pits. In such cases, prepare a fresh solution of 1 1/2 oz. (3 level T.) of lye per 1 gal. water and allow it to cool. Then discard the used solution and pour in the fresh. Let the olives stand until the solution reaches the pits, then follow the procedure in steps 3 to 5.

- **3.** Pour the lye solution off the olives and throw it away. After the lye stage, you have a long rinsing stage. Then comes the brining period. And then you eat or can them.

- **4.** Rinse the olives twice in cold water, then cover them with cold water. Change the water 4 times each day until you can no longer taste the lye in the olives. This may take as long as 7 or 8 days. (For commercial packers, it takes about 4 days.) EXPOSE THE OLIVES TO THE AIR AS LITTLE AS POSSIBLE DURING THE LYE TREATMENT OR THIS RINSING.

- **5.** Prepare a salt brine containing 4 oz. (about 6 1/2 level T.) of salt per gallon of water. (If the solution seems too salty, reduce the amount of salt to 3 3/4 oz.) Dissolve the salt thoroughly, and cover the olives with the solution. Let stand for 2 days.

The olives are now ready to use. Store them in a cold place, preferably in a refrigerator. They are susceptible to spoilage. Refrigerate and use within a short period of time (2 weeks). Or you can make them last longer by brining.

- **6.** If you do not plan to use the olives within 2 weeks, prepare a brine using 8 oz. (about 13 level T. or slightly more than ¾ c.) of salt per gallon of water. Store the olives in this brine for 1 week. Then replace the brine with a solution of 1 lb. (26 level T. or about 1 ½ c.) salt per gallon of water. After 10-12 days, put the olives in a fresh brine of 1 lb. of salt per gallon of water. In this strong brine, it may be 2 months before your olives begin to deteriorate.
Freshening from Holding Solution. Remove olives from holding solution and soak them overnight in fresh, non-salted water. By then they should be nice. They won't keep now. Use them up within 3 days. If at any time your olives seem mushy, moldy, or bad smelling, don't even taste them. Throw them out.

Canning Olives? Since green olives will keep for months simply refrigerated, it makes sense not to can them. Olives are quite low in acid. A food specialist told me that in California the 2 most common sources of botulism poisoning are home-canned taco sauce and home-canned olives.

Anonymous Olives. This letter wasn't signed. “Home-cured olives are such a treat. They are easily done, but you must have to follow instructions closely or you will fail. First have everything you're going to use ready and clean. The olives should be freshly picked and I always make the green ones. I worked in an olive curing plant and the black ones are more difficult to get just right. The olives should be graded so all are the same size so as to cure at the same rate. Throw away all bruised or cut ones. This recipe is to cure 40 or 50 lb. of olives. A wooden keg is best but you can use a crock jar. Only you need a drain hole at the bottom and you do not naturally have that in a crock. I used to use an old wooden washing machine. Dissolve 1 can of lye in 5 gal. cold water. (Soft water works better. Do not use fluoridated water.) Stir with a long wooden stick so the lye fumes don't burn your hands. Now gently pour olives into lye solution. Water will cover olives. Stir gently every few hours to get them well soaked in the solution. Keep them in there until the lye almost reaches the pit. The pit turns lighter. You can cut one in half and see if it is still bitter. You can taste it but do not let it stay in your mouth. Spit it out and rinse your mouth. When the lye has almost reached the pit, drain and cover with fresh water. Change the water every 12 hours for 2 days and be careful not to bruise any of the olives. If you see slick or cut ones take them out. “Now place your olives in a second lye solution using 1 lb. lye to 6 gal. water. Always use cold water. Allow olives to remain in this solution for 4 to 5 hours, or until the lye reaches the pit. You will know when you cut them open. “Drain off the lye and cover with cold water. Change water every 12 hours for a week. Then cover with brine. To make the first brine, use 2 T. salt per 1 gal. water and let stand 1 day. For a second brine, use 2 T. salt per 4 gal. cold water. Allow to stand 1 day. For your third brine, use 2 T. salt to 6 gal. water and allow to stand 2 days. For your fourth brine, use 2 T. salt to 8 gal. water and allow to stand 3 days. Now make a final brine using 1 T. salt to 10 gal. water. Bring this to a rolling boil. Skim scum, let cool, and cover the olives. Have the last brine ready to go over the olives right after you drain them of the next to last brine.”

Keep these olives in a holding solution, same as step 6 in the method above.

Process for Dark-Ripe Olives. This process is more complex than the one for green-ripe olives. The purpose of it is to make the olives dark-brown or black. Start with green, straw-colored, or cherry-red olives. It is best to use fruit that is all the same color (the same degree of ripeness) and nearly the same size.

1. First Lye Treatment: Prepare a solution containing 1 ½ oz. (about 3 level T.) lye per gallon of water. (Follow above directions for preparing the lye.) Pour the solution over the olives and let stand until it penetrates the skins. (Start checking the olives after 3 hours, and then check them every 30 minutes.) Remove the lye solution and expose the olives to the air in the container in which they were treated. This helps give the olives their dark color. Stir the olives 3 times during the first day they are exposed to the air.

2. Second Lye Treatment: Prepare a lye solution of the same strength as for the first lye treatment. Pour this over the olives and let stand until the solution penetrates ⅛-⅛-inch into the flesh. Remove the lye and expose the olives to the air for 1 day, stirring as before.

3. Third Lye Treatment: Use a lye solution that is the same strength as the first lye treatment. Pour it over the olives and let stand until it penetrates ⅛-⅛-inch into the flesh. Pour off the solution and expose the olives to the air for 1 day, stirring as before.

4. Fourth Lye Treatment: Make a solution of the same strength as for the first lye treatment. Pour it over the olives and let it stand until it penetrates ⅛-⅛-inch into the flesh. Pour off the solution and expose the olives to the air for 1 day, stirring as before.

5. Fifth Lye Treatment: Make a lye solution using 2 oz. (about 4 level T.) of lye to 1 gal. water. Pour this over the olives and let stand until it penetrates thoroughly to the pits. Pour off the solution and expose the olives to the air for 1 day, stirring as before.

6. Rinsing: Cover the olives with cold water. Change the water 4 times daily until the olives no longer taste of lye (up to 7 or 8 days).

7. Holding Solution: Cover the olives with a holding solution and store as described for green-ripe olives.

Freezing Ripe Mission Olives. You can preserve pickled ripe Mission olives by freezing, but other olive varieties soften badly when frozen and thawed. You can freeze Mission olives processed either by the green-ripe or dark-ripe method. Cover them with a brine made with 4 oz. (about 6½ T.) of salt per gallon of water. Boil for 10–15 minutes. This will lessen the softening from freezing. Discard the brine and chill the olives in cold water.

Pack the olives without brine in rigid cartons, glass jars, cans, or used coffee cans. The package should be moisture-vapor resistant to prevent drying out. Seal coffee cans with freezer tape. Tightly seal other types of containers in the usual manner. Quick-freeze the packaged olives and store in the freezer.

Before serving, let the olives thaw thoroughly. If desired, roll the thawed olives in olive or salad oil mixed with chopped garlic or other seasoning and let stand overnight.

Drying Ripe-Processed Olives. You can dry processed green-ripe or black-ripe olives in a home dehydrator or in the sun until bone dry. If you use a dehydrator, dry at 145–150°F. The dried olives will keep well in airtight food-grade plastic bags, glass jars, or metal containers. However, they keep best when refrigerated or stored in a home freezer.

Drying Ripe-Processed Olives can be safely used in canning and other foods as described for fresh olives.

Brined Greek-Style Olives. Always use mature, full-colored (dark-red to purplish-black) fruit to prepare this style of olive. You can use any variety, but be sure the fruit is firm and harvested before frost. It is most common to use the Manzanilla and Mission varieties. The cured olives may be
more or less shriveled because of the high salt brine used to preserve them. Some of the olives may fade in color during curing. In general, they tend to darken again when exposed to air.

How to Prepare Greek-Style Olives

1. Sort out defective fruits.
2. Place good olives in a container that can be made airtight. A 1-qt. glass jar is the smallest size recommended.
3. Cover the olives with a brine containing 8 oz. of salt per gallon of water (see step 6 under Spanish-Style Green Olives, below). Fasten the lids loosely. Store the olives at 60–80°F.
4. At the end of 1 week, replace the original brine with one containing 1 lb. of salt per gallon of water, again leaving the covers loose.
5. After 15 days, replace the brine with one containing the same concentration—1 lb. of salt—and seat the covers firmly.
6. If pressure forms, carefully loosen the cover to release the gas. Then close it firmly.
7. If brine spews out, replace it with more containing 1 lb. salt per 1 gal. water.
8. If you prefer less bitter olives, you can replace the brine at 1 month intervals for 2 or 3 months after step 4.
9. If you keep the olives airtight in brine, you can store them for at least 1 year, if the container cover does not corrode. There is no danger of spoilage or possible toxicity because of the high salt concentration of the brine.

10. You can eat the olives within 2 months after preparation if you like fairly bitter olives. In any event, after 2 months in the strong brine, you can use them for cooking in tamale pies and similar dishes. It is desirable to soak the olives in water overnight to reduce the saltiness before eating them out-of-hand.

Store any desalted, uneaten olives made by this method in the refrigerator, in a solution containing 1 part red wine and 1 part red wine vinegar, with a layer of olive oil floating on the surface. Before serving, since the olive oil may congeal in the refrigerator, allow the olives to sit at room temperature until the oil has melted.

Black Olives. The black olive procedure takes longer. The big difference is that the olives have to be exposed to the air as part of the process.

1. Mix 3 level T. lye per gallon of water and soak your olives in it until it merely penetrates the skins. As little as 3 hours may do it. Check often so you don't have an overdose.
2. When the lye has just penetrated the skin and not the flesh, pour off the lye solution and let the olives lay out in the air for a day. Stir them every few hours.
3. Now give your olives another lye bath until the lye has soaked in another \( \frac{1}{6} \) of an inch. Then pour off the lye water and let the olives lie in the air again, stirring every few hours.
4. Again lye bathe them until the lye has gone in \( \frac{1}{6} \) of an inch. (No wonder everybody thinks this procedure is too hard!)
5. Now give them a new solution of 4 level T. lye per gallon water. Leave them in there until it soaks to the pits. Pour off the solution and give the olives another day of fresh air.
6. Now cover them with fresh water, changing every few hours all day long until the lye taste is gone. Freshening will take about a week.
7. Now give them the brining treatment and can them like green olives.

Oil-Cured Greek-Style Olives. Make Greek-style olives from mature olives that are dark-red to black. Mission olives are commonly used, but any variety will do. Use smaller olives because larger ones get soft. The olives will become shriveled since they are salt-cured. These olives are salty and slightly bitter, and you may have to acquire a taste for them.

1. Cover the bottom of a wooden box with burlap. Weigh out 1 lb. salt for each 2 lb. olives. Mix the salt and olives well in the box to prevent mold from developing. Pour a layer of salt over the olives to a depth of 1 inch. Place the box outdoors so the brine forms won't ruin the floor.
2. After 1 week, pour olives and salt into another box, then back into the first box to mix them. Repeat this mixing process once every 3 days until the olives are cured and edible. This usually takes about 30–35 days. Stir things up as gently as possible. Remove any olives that have gotten soft or broken.
3. Sift out most of the salt through a screen. Dip olives in a colander into boiling water for a few seconds, drain, and let dry overnight.
4. For storage, add 1 lb. salt to each 10 lb. olives. Mix olives and salt and put the olives in a cool place. Use within 1 month, or store in a refrigerator (they'll keep up to 6 months) or home freezer (they'll keep up to a year) until used.

Just before using, coat the olives with olive oil by dipping into olive oil. Or put them in a large pan or box and sprinkle a little olive oil over them. Work the olives with your hands to coat them with oil. But don't oil if you plan to use the olives for cooking.

Don't worry because they look all shriveled up and wrinkled. That's how Greek olives always look! This type of olive is useful for flavoring stews, tamale pie, spaghetti, and as a relish eaten out-of-hand.

Using Olives. Use olives to decorate main dishes or eat as finger food. Add to pasta sauce, chopped, to salads, or any meat soup, or baked meat, or omelet mix.

STUFFED OLIVES. Remove the seed. In its place put a strip of pickled pimiento, a nut, or some other tasty morsel.

Homemade Olive Oil. Many people have asked me how they can make their own cooking oils. This is the only system I've ever been able to find that seems halfway possible for people to do on their own. The recipe was written by the late WV Cruess, who was Professor of Food Technology at the College of Agriculture, University of California, Berkeley, CA.

There are 2 ways you can make homemade olive (or any other) oil: by grating, simmering, and skimming, or by pressing it out. By these processes, you get only two-thirds as much oil as from a commercial press. Still that isn't bad for homemade.

Grate/Simmer/Skim Extraction. Ordinary lye will be needed. Make up a solution of \( \frac{1}{2} \) lb. lye per 1 gal. water, using an agate ware or iron pot (not aluminum!). A small basket of wire screen such as is used for making French-fried potatoes will be needed, or a piece of cheesecloth can be
used. Heat the lye solution to boiling and while it is boiling, dip the olives in it for about 20 seconds. The time needed will vary with the toughness of the skins. Leave the olives in the lye until the skins are softened—that is, practically dissolved. Then plunge them into cold water for a few seconds to stop the action of the lye. Place the lye-treated olives on a piece of fly screen tacked to a frame over a large dishpan. Rub them on the screen until the flesh has separated from the pits and dropped through the screen into the pan. A heavy pair of rubber gloves is necessary in this process to prevent your hands from becoming badly stained and roughened by the lye and olive juice.

Place the pulp, which should now be of a pasty or mushy consistency, into a pot with about 2 or 3 times its own volume of water. Heat to simmering, stirring constantly, for about 1/2 hour. Set it aside for several days to permit the oil to rise to the surface. Usually a fair yield of oil can be obtained by skimming it from the surface of the pulp. The pulp may then be boiled a few minutes with more water and allowed to stand again. The process should be repeated several times. The secrets of success are to rub the olive flesh to a fine-grained pulp and always use a large excess of water with the pulp. The yield of oil is also sometimes increased by adding about 1/4 lb. salt per gallon of water used with the pulp.

Oil obtained by this process must be washed and should be filtered as described later.

**Pressure Extraction.** The simplest way to prepare olives for pressing is to place them in a strong sack, then hammer the sack with the broad side of an ax or with a heavy board until they are thoroughly crushed and broken up. The olives will crush even better if boiled a short time beforehand to soften them. Now press them in your store-bought or homemade olive press.

**Making a Homemade Olive Press.** Materials needed: a heavy auto jack, 2 lengths of steel cable or chain or heavy rope, 1 shallow wooden watertight tray, 1 piece heavy burlap material to hold the crushed fruit, a pair of 2-inch by 10-inch by 16-inch boards for the bottom, a pair of 2-inch by 4-inch by 20-inch boards for braces, and 4 threaded eyebolts with nuts. Start by nailing the bottom together. Put the 2-inch by 10-inch boards side by side and nail them onto the edge of the 2-inch by 4-inch boards as shown. Next build a tray or simple box and caulk all joints to insure watertightness. And set this on the bottom. Then drill holes for eyebolts in the 4 corners of the bottom as shown, and insert eyebolts. All that is left is to set the jack up and measure and attach the cable.

**The Pressing.** You can press either green or black olives for oil. Green makes the best quality oil, but less of it. For kitchen oil, don't press hard enough to crack the pits. There's oil in them, but it's good enough only to make soap with. The oil from a first pressing is highest quality and called the "virgin oil." Green olives press best if first dried a week out of direct sun.

Place the crushed fruit and pits in a piece of heavy burlap and fold the edge of the burlap in to give a pressed cake about 10 inches square and about 4 inches thick. Make 2 of these and place them in the press. Press slowly until no more juice can be obtained. Save all juice and oil pressed from the fruit. The pressed pulp should now be boiled with an equal volume of water and pressed a second time. Repeat boiling and pressing again. Usually a fourth heating and pressing will pay. Combine all of this pressed liquid and allow it to stand in a tub or barrel overnight. The oil can then be skimmed off.

**Clearing the Oil.** Oil obtained by either of the above methods will be bitter and not clear. Use any of the following methods to clear it.

**Method 1, Water Washing.** Prepare a bucket or a 5-gal. can with a hole and faucet or cork near the bottom. Place the oil in this container and add an equal quantity, or more, of warm water. Mix oil and water by stirring for several minutes. Allow water and remaining solids to settle for several hours. Draw off the water and replace it with fresh warm water. Stir, let it settle, and draw off water and solids again after several hours. Repeat until the oil no longer has a bitter taste. Usually 2 days' washing will be sufficient.

The oil will be cloudy and mixed with a little water. Now pour it through filter paper from the drugstore or a coffee filter placed in a funnel over a bottle or jar. Oil filters slowly. Do not become discouraged if it requires several days for it to run through the filter. A way to hurry it would be to filter it through several layers of cheesecloth—again and again. Then bottle as below. Some oil makers swear that the oil needs aging for several months to have the proper flavor. Method 2 has aging built-in. For method 1, age in bottles away from bright light. Too much light will cause it to lose color and flavor. But a warm room will help it age more rapidly. The oil will also age faster if the bottles are only 1/4 full, and if a small piece of cotton is used to close the bottle.

**Method 2, Siphon System.** In this case you take the oil off the top instead of the water off the bottom. Start by straining the oil through several layers of cheesecloth into glass containers (the glass is an advantage of this system). Let it settle a couple weeks. Then siphon the oil off the top, stopping before you get near the sediment. (Plastic tubing works well.) Strain again, settle again, siphon again. Five such cycles will give you quality oil. Now pour into sterile jars (don't heat), and add lids or cork to seal.

Once you break the seal on a jar of your olive oil, refrigerate it to prevent rancidity.

**Papaya:** The papaya is the most tropical of tropical fruits. Even the tree has an exotic look of the jungle about it. It isn't actually a tree. It is more of an overgrown 20-foot herb. It produces vast amounts of a delicious fruit that is also very nutritious. In appearance and taste it is much like a melon.
Varieties. There are a number of papaya varieties, different in sweetness, hardiness, and pollination requirements. Mexican varieties are less sweet and more hardy. If you’re going to grow only a few, I’d recommend the Solo Papaya, which is small and sweet and will pollinate itself.

Growing. The most important factor in growing a papaya is climate: they cannot abide chill. In the United States, the only suitable climates are in Hawaii, along the Southern California coast, and the Gulf coast. Temperatures below 30°F even for only a few hours, will damage the plant and/or prevent fruiting. Luckily, the plants can be grown in containers and brought indoors for cold spells. Most types of papayas need both male and female plants to fruit, and only the females bear papayas. The soil should always be kept moist but never wet. Fertilize frequently. Plant from well-washed seeds, 2 or 3 of them in a pot filled with a mixture of manure, sand, and loam.

Pomegranates: These can be grown from seed, by cuttings, or layering. Or order them from a nursery. They look like small trees. They are hardy in the Las Vegas area and have no insect problems. They flower beautifully for a good 2 months—brilliant coral trumpet-shaped blooms. The pomegranate is ripe for sure when it starts to split. (You can’t tell by the outside color.) Pomegranate juice will severely stain your kids’ clothes. Rosalind Creasy, in The Complete Book of Edible Landscaping, has recipes for pomegranate jelly, grenadine syrup, and pomegranate juice.

Prickly pear: Opuntia ficus-indica, prickly pear cactus or “Indian fig,” is the best known cactus fruit, but there are numerous edible cacti in the Opuntia and Nopalea cacti species. In general they will grow from zones 5 to 10. They grow well in containers so you can bring more-tender ones inside for cold weather if your weather gets below 20°F.

Varieties. Choose your species thoughtfully. Some are more hardy than others; O. opuntia is the hardiest. (See Cactus and Succulents, published by Sunset.) Edible types include N. chamaecereus (fruit and pads), N. dejecta (fruit and pads), N. cochenillifera (fruit), O. engelmannii (pads eaten fried), O. leucotricha (pads and fruit), O. ficus-indica (pads and fruits), and O. basilaris (flowers can be steamed and eaten).

There are new spineless varieties available, which cactus like to eat and which can grow in deserts where little else thrives, doing well in a well-drained rocky or sandy soil. Starts are available from Jim and Electra Elliott at Arizona Cactus Sales, 1619 S. Arizona Ave., Chandler, AZ 85248; 480-963-1061; www.arizonacactussales.com. Or Arizona Cactus: 520-432-7040; azcactus@primenet.com; www.arizonacactus.com. John and Vickie Dicus offer a “nearly spineless” Opuntia ficus-indica var. Burbanks Spineless, a rapidly growing variety called Opuntia ficus-indica var. Santa Maria, and the “Dinner Plate” cactus (Opuntia robusta), whose edible “almost spineless” leaves can grow as large as 16 in. across: Rivenrock Gardens, PO Box 196, Nipomo, CA 93444; www.rivenrock.com. Or shop at GreenDealer: 502-459-9054; PO Box 37328, Louisville, KY 40233-7328; king@dearde.net.

Planting. You can start a plant from either seeds or pads. If you live where cactus grows wild, just broadcast seed, cover with ¼-inch sand, and wait. Otherwise, plant in flats. It takes the seed months of a little dampness and a little sun to get going. Planting a pad goes faster. Let it cure a few days in sunshine, then plant right-side-up in moist sand. No fertilizer is needed, but they do need water at least once a month their first year. Not too much water, though; excess results in mildew or rot of these desert naturals.

Harvesting. It takes several years for the plant to get big enough to fruit. In spring, nice yellow (or orange) flowers bloom. The leaves are thorny, thick green extensions called “pads.” They’re edible and taken in spring. The flowers are followed by fruits, ready in the fall. The pads and fruits both have needles. Be careful not to get punctured. Old-timers pick fruit and pads with leather gloves.

Nopales. “Nopales” is the Mexican name for prickly pear pads served as a vegetable. To use, first get rid of the bristles on the pads by scraping them off completely or singeing or cutting them off like you’re cutting out “eyes” from a potato. Then peel and cut into large chunks, then boil in water. (Cooked nopales are still firm.) Drain and serve with salt, pepper, and butter. Or serve raw and sliced. Or add to a basic meat and vegetable soup or stew. Or fry sections.

Prickly Pear Fruits. These can be eaten fresh if you’re willing to spit out the seeds. Marion Stick is a woman of Native American descent who lives in Phoenix, AZ. Marion says Native Americans pick the fruit from cactus and make jelly and candy. The following recipes tell you how.

CACTUS CANDY. Marion makes this from the small barrel cactus. Take off spines and outer skin. Cut pulp across in 1-inch slices. Soak overnight in cold water. In the morning cut into 1-inch pieces and boil until tender. Drain and cool slowly in a syrup until syrup is almost gone. Watch so the pieces do not scorch. To make syrup for about 2 qt. cactus pieces, combine 3 c. sugar, 1 c. water, 2 T. orange juice, and 1 T. lemon juice. Bring to a boil and add cactus. When syrup is almost gone, remove cactus pieces. You may cover with powdered or granulated sugar.

PRICKLY PEAR JELLY. Pick prickly pears with leather gloves. Take off spines. Rinse the fruit and place in kettle, adding enough water to cover. Boil until quite tender, then squeeze through a jelly bag or jelly press. To every 2½ c. of juice add 1 (1½ oz) package powdered pectin and boil for couple of minutes. Then add 3 T. lemon juice and 3½ c. sugar. Stir often and boil hard for 5 minutes. Pour in jelly glasses. Adjust lids. Process 5 minutes.

Roselle: This attractive, tall (4–5-foot) annual, Hibiscus sabdariffa, also called “Florida cranberry” or “sorrel,” is grown for the fleshy cranberry-flavored red calyces that develop from the bases of its yellow flowers. It needs subtropical or greenhouse conditions with a long, hot summer. It grows fast and can be used in the South as an annual hedge. Plant like tomatoes, spaced 1½–2 feet apart.

Harvesting and Use. The plants are triggered to begin flowering when the days shorten, but too soon a frost will prevent the roselles from maturing. The roselles will be ready for harvest around 15 days after the flowers bloom. To harvest, just snap them off. The red calyces, called “roselles,” can be used fresh or made into a fruit sauce, or used to flavor jelly, iced drinks, or hot teas. Roselle juice is like cranberry in color and taste, but lacks cranberry’s bitterness. Dried roselles, or “Jamaica flowers,” can also be used as flavoring. Young roselle leaves and stems can be cooked and eaten same as spinach.
**ROSELLA JELLY** Cover the roselle with water and cook them until tender. Strain through a jelly bag. Measure the juice. Boil it 5 minutes. Add 1/2 c. sugar and 2 t. lemon juice per 2 c. roselle juice. Cook until it sheets from the spoon. Skim. Pour into your jelly jars and seal.

**SAPOTE:** Sapote (Sapotaceae) is also known as sapota, sapodilla, and the "chocolate pudding fruit." Marney Sapota, var. "Pantin" (Pouteria sapota) is a grafted plant that needs tropical conditions such as a heated greenhouse, available from Pacific Tree Farms: www.kyburg.com/ptf.

**TAMARILLO:** The tamarillo (Cyphomandra betacea), or "tree tomato," is grown in sub-tropical areas around the world. It's a beautiful plant with large leaves and a sweet smell that grows only about 8 feet tall.

**Planting.** Choose a wind-protected, warm site and well-drained, light soil. Provide reasonable watering. Tamarillo will grow from seeds (available from Southern Seeds).

**Harvesting and Use.** Your plants start bearing smooth, bright fruits in 2 years. They are sweet and acid and make good preserves and sauces, or can be cooked as a vegetable —good stewed or baked with any meat. They have tough outer skins that help them store well, but they must be peeled before eating.

**VINE, BUSH, AND BRAMBLE FRUITS**

*The Complete Guide to Growing Berries and Grapes* by Louise Riotte (Garden Way) pulls together most of the basic details about small fruits. For good readable advice on grapes see *Organic Gardening*, February 1972, p. 72. You can also get a lot of useful information on grapes out of the Henry Field Seed Company catalog.

This section is divided into 2 parts: the vine fruits are listed first.

**Grapes**

(For information in this section I am heavily indebted to Cass Turnbull, who knows so much more about grapes, their training, and their pruning, than I do.) Quite likely you can get started with grapes with cuttings from a neighbor who has them. You cut in the early spring before the sap has started to run, when it looks all dead. Don't prune grapes after the sap is running because they'll bleed like crazy. Cut off a length of stem with at least 5 bud spots on it. This is where the leaves will develop later. Stick it in your chosen place with 2 or 3 spots underground and the other 3 above. Roots will grow from those underground, and leaves from those above. Keep the ground soaked around them all that first summer. You may have grapes from them even the first year. If you're planting in a row, set cuttings about 2 feet apart. They can be by the side of a building if you want, but pick a sunny side. Supply a pole for climbing. When choosing grape starts, be careful to take slips off a good productive plant rather than just anything.

**VARIETIES AND PRODUCTION:** Green grapes make nice table grapes, but purple salad grapes are better for preserves and juice. Ours are some little green kind with seeds. Don't get in a hurry for production. Generally you'll have no grapes the first year you plant, very few the second, more the third, and then in the fourth year you'll start to get into real production—depending on how you prune. That's true of cold-weather grape types. You see, there are 2 basic kinds of grapes. One is your vinifera or California wine type. They are most common in warm climates. Thompson Seedless, also this type, is a good table grape. With these warm-climate grapes you can have grapes growing by the second year after planting. The labrusca varieties have slipskins and are cold-weather kinds of grapes. Concord is one. The Concord grape is a good producer. These do better in cold climates where they will give you a heavier production than warm-weather types will. Cold-weather types will do fine in New York. But they take at least 3 years to bear fruit. They bear fruit from the third, fourth, and fifth buds from the base of the vine. When you are pruning you have to be careful you don't cut away that fruiting wood. You'll find lots more info on commercial aspects under "Organic Grape Production," at www.attra.org/attra-pub/Grape.html.

**GRAPE PRUNING:** Cass wrote up this subject to help me: Grape pruning is daunting to the novice, especially to one who has inherited someone else's old, overgrown vine. Don't worry. In grape pruning, as with most pruning, there is a large margin of error. If you avoid the big mistakes you can do a decent job until time and experience teach you the rest. The 2 most frequent mistakes I see are not pruning at all and simply shearing or whacking all canes back to the arbor or trellis and leaving a big, tangled clump.

**A Grapevine Story.** An early settler planted a grape vineyard. It grew fine for several years, but eventually the settler moved on and the vines were left unpruned and neglected. Eventually they grew out of site and rambled along the ground. The grapes were poor in quality and out of reach. A new owner bought the property with the intent of raising livestock and pack animals in the forgotten fields. A year or two later the animals had nibbled back all of the vines. Thereafter the vines returned and fruited magnificently. The moral: Any ass can prune a grapevine.

**Controlling Grapevine Size.** If you have planted or acquired grapevines, you will soon have a lot of experience pruning them. That's because the primary reason for pruning grapevines is to keep these "rampant plants" from growing up and covering nearby houses and trees. This extensive annual growth is the modus operandi of most vines. Don't take it personally. Furthermore, if you neglect to prune, you will find that all the grape clusters appear way out of reach at the ends of your enormous vine.

**Maximizing Production.** On old, let-go vines, you will find many, many clusters of grapes, but they will be small and of poor quality. Shortening and thinning allows more energy and light to reach fewer buds, making the fruit bigger and bigger.

**How Much Grape Pruning Is Enough?** Take off between 60 and 80 percent of the foliage and old canes every year. That looks like a lot, but really it isn't for a grapevine. Yes, it is possible to overprune. The plant won't die, it will simply stimulate rapid and rampant regrowth. Such growth has bigger than normal leaves and fewer fruiting buds, meaning fewer grape clusters. This is one reason that severe pruning, which is commonly done to renovate an old vine, is often spread over several years.

**When to Prune.** Most grape pruning is done in the dormant season, meaning mid-winter. If you prune too late (late February or March, in Seattle), your grapevine will
You may want to thin out clusters of young grapes. Just cut some clusters off, or parts of clusters off, to channel more energy into what's left. Here again this is not essential, but it will make the remaining grapes bigger and better. I like to do a little touch-up pruning in the summer to get more light to the grape clusters.

**Thinning Grape Clusters.** Early in the growing season, you may want to thin out clusters of young grapes. Just cut some clusters off, or parts of clusters off, to channel more energy into what's left. Here again this is not essential, but it will make the remaining grapes bigger and better. I like to do a little touch-up pruning in the summer to get more light to the grape clusters.

**GRAPE-PRUNING DEFINITIONS**

**Shoot.** New supple, 1-year-old, green growth.

**Cane.** A 1- or 2-year-old shoot. On it are buds that never grow out unless they are pruned back, buds that become new shoots, and buds that become flowers and fruit. A good, young cane is about pencil thickness and is smooth and tan, not brown and shaggy.

**Spur.** A cane shortened to 1 or 2 buds, about 3 inches long.

**Fruiting Arm.** An older spur that is cut a little farther out each year until it becomes a thicker, older, more permanent feature a few inches long. When a fruiting arm becomes too old, pick a new cane originating on the trunk or scaffold and train it as a replacement (spur prune). Then cut back the old arm.

**Scaffold.** Main side branches. Originally these were the canes arising from the trunk that you trained along the wires or across the arbor. They have been cut back to be 6-10 feet long and kept year after year as framework. They are now fatter, browner, and shaggy.

**Head Prune.** A system of pruning in which canes are cut back to the trunk, not scaffolds.

**Trunk.** The main trunk. Wood is thick and shaggy.

**TRAINING A NEW GRAPEVINE**

**Support for a New Vine.** The first 4 years of pruning are done to create a strong, compact framework for your vine. Too commonly I see grapevines being trained on thin posts with wire trellises. Be sure your main framework is sturdy: Trunk.

**Space for a Grapevine.** Give your vine a lot of room. Even with annual pruning they require at least 6-10 feet in which to grow. Early training of grapes doesn't make sense to the logical mind. The first winter after planting you cut the poor tiny thing down to as few as 2 buds from the ground (3-6 inches). This is done to force rapid regrowth and a strong trunk. The next spring it zooms up and sends out side branches. In the spring or summer you cut off the side branches and keep tying the main stem (or sometimes 2 stems) onto the stake to hold it up. Don't tie too tightly, or the ties might girdle the vine.

During the next winter, whack it back to half of its present size (about 2 feet). Really this is the way it's done! Let it grow through the summer. Gently tie it every 6 inches or so, as it grows up the post or stake. Again, remove side branches (shoots) and basal shoots (those coming from the base or ground level). When the vine finally reaches the lowest of the wire supports, allow 2 shoots (one on either side) to grow along the wire, tying them in place temporarily if need be.

**TRAINING A NEW GRAPEVINE**

**Support for a New Vine.** The first 4 years of pruning are done to create a strong, compact framework for your plant. You will need to cut back your scaffolds the first year to about 10 buds (2 feet or so) just like you did the trunk. This forces them to become thick and sturdy and causes them to set up more buds close to where you'll want them. The shoots arising from the scaffolds are similarly cut back, becoming "fruiting arms" an inch or so long. Arms should be spaced about 6 inches to a foot apart on the scaffolds.

**SYSTEMS OF PRUNING**

**Spur Pruning.** When you spur prune, you cut back a cane until it has only 2 or 3 buds from the scaffold or fruiting arm. Do this in the winter. Spur prune canes, which are spaced every 6 inches or so apart along the scaffold, and cut off all other shoots and canes entirely. This keeps crowding down. The 2 buds will grow into new canes and set fruit next year. The next winter cut off the outer one of the 2 canes and shorten the other cane to 2 buds. Repeat annually.

This is the method used for most European varieties except Thompson Seedless (the most common supermarket grape). European grapes are Red Malaga, Ribier, Perlette, Muscat, Cardinal, Tokay, and California wine-type varieties.

**Cane Pruning.** This is also known as "renewal pruning." Some varieties won't set fruit if you spur prune all canes annually. These are the American grapes such as Delaware, Concord, Niagra, and Pierce, as well as the Thompson Seedless. These fruit form growth farther out on the cane. Therefore, you cut back half your canes (the newest ones) about 2-4-foot lengths (8 to 14 buds) every year. Wrap or tie the canes gently around the support wires. Cut the other half (meaning the older canes that bore fruit this last summer) way back, making them into spurs. This type of spurring is done to ensure a continued supply of canes that are close to the trunk or scaffolds.

**The Shotgun Method.** If you're like me, you are probably faced with an old tangled mop of a grapevine monster, and you have no idea what type it is. Try the shotgun method. Cut out 60 percent (or more) of the shoots and canes entirely back to bigger scaffolds or to the trunk. You follow each chosen victim with your eyes, cutting it in many places and unthreading it from the tangled mass. Keep an eye on the base or ground level. When the vine finally reaches the lowest of the wire supports, allow 2 shoots (one on either side) to grow along the wire, tying them in place temporarily if need be.
A hundred pounds a year isn't enough for us."

What's left is the big fat trunk, the scaffolds you wish to keep, and many (but now far, far fewer) canes. Shorten some canes to 2 bud spurs (3 inches) and shorten most of the rest to 10 or 14 buds (2–6 feet). If it's on an overhead arbor, you may care to leave some canes longer as framework.

Repeat this procedure annually. By careful observation you may be able to tell which type of grape you've got. Otherwise this method should suffice to keep your grapevine producing and in check.

**Preserving Grapes**

**Raw Storage.** Grapes, like pears, are a late summer crop—at least around here. If you pick only good ones and keep them in a cold, moderately moist place, they will keep a month or more. Catawba keep the best.

**Drying.** When grapes dry you have raisins. I used to think that raisins were some kind of tropical fruit that grew in California. It was a real surprise to me to learn that raisins are dried grapes and prunes are dried plums! Grapes are one of the harder fruits to dry—more difficult than any of the large pitted sorts, which are the easiest. Any sweet grape can be dried. Seedless varieties are obviously preferable. Good raisin varieties are the Thompson Seedless, Black Malaga, Black Thompson Seedless, and Muscat.

**Making Raisins.** Let your grapes ripen on the vines until they are sweet as you'd expect them to be before they start going bad. Then pick the branches, cluster by cluster. Spread them out in the sun to dry and turn them over occasionally. It may take a couple of weeks or so. Once the raisins are dried you can remove them from the stems for storage or store them on the stems as you prefer. Or you can dry seedless green grapes at 170°F for at least 24 hours in an oven.

Cris Wilhite, of Fresno, CA (the “raisin capital of the world”), wrote me: “We cut the grapes, lay them on [a lead-serve warm.

**GRAPE SAUCE**

Cook ½ c. raisins in a little over ¼ c. water. When the raisins are soft, strain and reserve ¼ c. water drained from them. Combine ½ c. brown sugar and the raisin water and cook together 5 minutes. Then add 2 t. butter and ½ t. vanilla. Mix, add raisins or not as you prefer, and serve warm.

**GRAPE JUICE** The Concord and Catawba varieties are especially fine for juice, but you can make it from others, too. The key to enjoying homemade grape juice is knowing that you want to dilute your juice with water to taste when you serve it. The floating crystals are tartrate (cream of tartar). In grape juice you have a natural concentrate. If the grapes are ripe and sweet you don't need to add sugar. If you add more sugar to your grape juice you get the equivalent of a syrup.

Use only sound, ripe grapes. Let them ripen on the vine, and after you pick them keep them out of the sun until you have a chance to pick off the stems and wash them. Mash the grapes with a potato masher or in a press. Cover the red grapes and Concord grapes with water and heat to 145°F. Don't heat white grapes. Put the pan contents in a cloth or fruit press. Work the sack gently so that you extract all the juice or just let it hang all night. If you want clearer juice let the extracted juice stand overnight in a cool place. Then pour off the top. The pulp will have settled to the bottom. If you have white grapes be careful not to crush the seeds. To can grape juice, use the recipe for canning apple juice. When serving the juice I dilute half and half with water. Early in the season the children don't care much for grape juice, but by about February when the apples are gone they really start to relish it, and I do too.

**HOMEMADE FRUIT COCKTAIL** Green grapes can be made into homemade fruit cocktail. Just cut your fruits small. Use whatever you have—strawberries, peaches and so on. Combine with a honey syrup and can or freeze. Although you never see grapes listed in regular canning lists they can be canned.

**Canning Grapes.** Just remove the stems, pack in your jars, pour over hot syrup or even plain water. Process in a hot-water bath 15 minutes. I have a friend who has no freezer and whose family lives off their own produce. She cans quarts and quarts of whole grapes, strawberries, and raspberries every year.

**SIMPLE CANNED GRAPES** Into a clean sterile quart jar put 1 c. any kind of grape. Add 1 c. sugar or ½ c. hot honey. Fill the jar on up with boiling hot water and seal it. Takes about a month to be ready. Tastes good.

**Freezing Grapes.** I used to think you couldn't freeze grapes because that's what I'd read, and I'd never tried different. Then a friend told me he freezes grapes and they freeze very well. He said he takes the grapes off the stem, washes them, and bags them up with no other treatment in plastic bags. He said that they were practically like fresh when thawed.

**GRAPE PUNCH** Combine the juice of 2 lemons and 1 orange, 2 c. grape juice, and 2 c. water. Sweeten to taste.

**GRAPE ICE** Pulp 3 lb. grapes. I like the little green seedless ones. Then you can keep the pulps and skins in the syrup. If you are using seeded grapes you'll have to pick the seeds out and put the grapes through a sieve, in which case you'll lose a lot of good stuff and good time, too. Add ¼ c. (or more) honey and mash well. Freeze, stirring occasionally. It takes quite a while to freeze. Serve when it is barely beyond the “slush” stage. This is nice with a whipped cream topping, or plain.
Kiwi

These have also been called “Chinese gooseberries.” Kiwis started out in China, then got to New Zealand, and finally to California. Commercial size and quality patches can grow even in northern Washington. Kiwis grow on a grape-type vine, are large as a lemon, and have no connection with the regular gooseberry. The first importers of the fruit renamed them “kiwi fruit,” and that’s what they are called in American supermarkets.

Here’s Cass’s wisdom again: An interesting thing about kiwis is that most varieties are dioecious, meaning male and female flowers are on different plants. You need 1 male plant to service about 7 females. Of course, only the females will fruit. (Some newer cultivars are self-fruitful. Finding and planting one of these may save you a lot of room.) It may take from 2 to 8 years for a vine to begin producing. Kiwis also need a long summer to ripen on the vine. In short season climates like mine [Pacific Northwest], we pick the fruit after the first frost and ripen it inside in a cool storage area.

Pruning Kiwi Vines: Kiwis are like grapes in many respects—only more so. Their growth is so extensive that summer pruning is essential, as often as once a month, to keep the vine from running down the block and covering your neighbor’s house and trees. They need even more room to live than grapes (10 by 16 feet on an arbor, 3 by 16 feet as an espalier). Prune them in the winter as well. Early training for kiwis is similar to that for grapes. Prevent the main stem from twisting around its support stake. Once mature, kiwis are pruned a lot like “spur-type” grapes. In the winter cut back all of the new rampant growth to the original spur system, only a little farther out. This means that you will cut to 2 or 3 buds beyond where it last fruited. However, your spur system will eventually get old and crowded. You will need to renew it by cutting it back severely or starting it over by cutting back to the scaffolds.

Passion Fruit

This wonderful perennial and evergreen vine from Brazil will grow only in a hot, humid subtropical zone. It can endure a brief light frost, but that’s it. Because it will grow in a container you have that option also, pruning to keep it the size you need. The flowers are unusual and very beautiful. It grows quickly and generously produces fruit in 2 years. The vine can climb as high as 30 feet. There are several varieties, some better for flowers, others for fruit. The fruit will be mature about 3 months after the flower bloomed. *Passiflora edulis* fruits from summer through fall. Passion fruit has an outer juicy orange pulp and seeds in the middle. You can juice it for any juice use: punch, syrup, jelly. Seeds are available from Southern Seeds. Several varieties, guaranteed down to 25 or 26°F, are offered by Pacific Tree Farms.

Bramble, Bush, and Other Tiny Fruits

It’s a good idea to have several varieties of berries, as well as a good orchard. Your first strawberries will bear in June. Raspberries mature in July. Blackberries and wild berries are on in August and September. You will have berries all summer long.

Berry Picking: When you pick berries that have thorns, wear long stockings with the feet whacked off—not nylons—or some similar heavy protection on your arms so you won’t get too badly scratched. A leather belt around your waist with a half-gallon can hanging on it is handy, and then you can empty the berries into a big bucket when the little one is full. Don’t worry about leaves and such when you’re picking. You can put the berries in water when you get home, and leaves will float to the top; you can just scoop them away.

Runner Reproduction: Strawberries and many other berries reproduce by “runner.” Strawberry runners travel on top of the ground, then stop about a foot away from the parent plant, put down roots and become a new, independent strawberry plant. You just whack the connection, dig up the independent plant, and reset it in your ground where you want it.

Berries for Free: When gardening neighbors are cleaning out unwanted berry runners in the spring and cutting back perennials, they can give you all the good starts you’ll need if you just give them advance notice that you would like to have them. They have to dig them out anyway from between their rows, and if they didn’t give them to you then they would throw the starts away. Berry plants planted from suckers bear no fruit the first year; they will bear fruit the second year.

Nursery Starts: If you can’t get berry and grape starts from neighbors, buy from your local nurseryman rather than by mail-order, unless you live someplace where there are no plant nurseries and mail-order is the only answer. Almost all the big catalog seed houses carry a wide selection of berry cuttings, but some specialize in them.

Basic Berry and Tiny Fruit Recipes: If you have some unusual kind of berries or small fruit for which you can’t find specific recipes (there are umpteen different kinds of berries), just substitute in recipes that call for a similar fruit because they are very similar except for the sweetness/tartness, which you can taste-test and add more or less sweetening as needed. For preservation methods, experiment! It may be better to freeze or can. Or make leather. You have to find out.

Drying Berries: Dried berries may not be as agreeable to eat out of hand as the larger fruits, especially seeded berries. Even unseeded ones may turn out quite tough, dry,
berries again with water, boil 5 minutes. Drain off the juice and save it. Cover the berries again with water, boil 5 minutes more, drain again and save the juice. Squeeze the seeds and stuff left if you want. Boil again if you think it would help. You can use your busy woman's berry juice as a base for jelly or for juice. Each successive boiling will make a lighter-colored juice. Sweeten to taste.

**WONDERFUL BERRY DRINK**  Boil 2 qt. water with 1/3 c. sugar or 3/4 c. honey for 3 minutes. Then crush 2 qt. raspberries, blackberries, or strawberries and pour the hot syrup over the fruit. Cool. Strain. Add 1 c. lemon juice and ice cubes, and serve.

### Brambles: Red and Black Raspberries and Blackberries

#### PRUNING BRAMBLES:
The pruning of brambles is different from that of trees. Since new fruit grows on new canes yearly, you do a fair amount of complete pruning; that is, removing entire canes that have already produced their crop. Every year blackberries send up new shoots from their root systems. The size of these canes by the end of the summer depends on local conditions: soil, moisture, and light. But fruit is borne on these canes only in the following year, largely on lateral branches, which grow during the spring of the second season before flowering. In the wild, after these canes finish bearing, their leaves die and discolor, and the dead canes stand in place until they slowly fall over, decay, and rot. If a stand is particularly thick, it will soon become choked with those used up canes. If you keep the berry patch clean of dead and dying canes, you can significantly extend the life of a good stand. And the amount of fruiting wood available can be increased significantly by pruning. If you head back the top of the canes the first spring, the plant will put all its energy during the second season into the lateral branches, the ones that produce the fruit. Furthermore, blackberries under cultivation can be spaced and trained in such a way that a careful picker will not be so scratched up by the thorns. When pruning out at the end of a season, cut the canes on the ground, but do not pull them down to remove them. Cut them all off in an area at once, then stand up and lift out the canes—less tearing of leaves on the new canes that will bear next year's fruit.

#### BLACKBERRIES:
They grow wild and they grow tame. They are called "blackberries" and they are called umpteen other names like "dewberry" and "thimbleberry," "black raspberry," "flymboy," "wineberry," "nagoonberry," "cloudberry," "wild raspberry," "salmonberry," "blackcap," and "bake-apple." The line of distinction between blackberries and raspberries in the wild isn't very clear, and there are so many different varieties with so many different sizes and colors—suffice it to say they are all good to eat. If you live where they grow abundantly you have a wonderful ready-made free source of small fruit. Blackberries make good out-of-hand eating and good jam and jelly. You can make a hedge of blackberries. If you pick them prematurely they won't be as sweet as later on. Let them stay on the bush until they are really, really ripe, and then they will be sweet and not sour tasting. The "dewberry" variety of blackberry has huge beautiful berries but it isn't as winter hardy as some others. You can propagate blackberries by the volunteer suckers that grow or by root cuttings. Vine-type black-
berries like youngberries, boysenberries, dewberries, and
loganberries seldom sucker but can be propagated by leaf bud cuttings, except for some fancy thornless varieties. If you took a root cutting of an improved thornless variety, the new plant would revert to the old thorny kind. A 2-inch segment is enough of a root cutting to plant.

**BLACKBERRY SYRUP** Crush well-ripened blackberries and add one-fourth as much boiling water as you have berries. Let stand 24 hours, stirring frequently. Strain. Add 1 c. sugar for each quart of juice and boil slowly for 15 minutes or until you have the density you want, and then can it.

**LOGANBERRY ALE** Combine 1 c. loganberry juice, the juice and grated rind of 4 lemons, 1 c. sugar, 2 c. ginger ale, and 3 c. water. Let stand a couple hours to mellow. Garnish each glass with a mint sprig and a lemon slice.

**LOGANBERRY SPECIAL** Combine 2 c. loganberry juice, 1 c. raspberry juice, 1 c. lemon juice, and 3 crushed mint leaves. Mix and serve over crushed ice.

**RASPBERRIES:** These, like blackberries, are a very soft berry. The soft berries do better frozen than canned because they cook up so easily. They make good jam, jelly, sauce, and juice, too, but are nicest of all fresh. Raspberry plants don’t last forever. A started raspberry row will last 7–10 years. So after the fifth year start a new row so it will be bearing only once on a cane so you prune by cutting out the berries. Let stand a couple hours to mellow. Garnish each glass with a mint sprig and a lemon slice.

**RASPBERRY JUICE** Use fully ripe, juicy berries. Wash in cold water and drain. Crush and heat the berries slightly to start the flow of juice. Strain in a jelly bag to get the juice.

**RASPBERRY-APPLE JUICE** Combine half raspberry juice and half apple juice.

**RASPBERRY-MINT DRINK** Combine 1 c. sugar or ½ c. honey, 1 c. water, and the grated rind of 2 lemons. Cook, stirring over low heat until your sweetening is dissolved. Boil 5 minutes more. Cool. Add 2 c. crushed raspberries, 1 c. lemon juice, and 4 c. water. Serve with some mint leaves in the bottom of the glass (and in the pitcher) and a mint leaf on top.

**The Non-Bramble Berries**

**BARBERRIES**

**BARBERRY JUICE** Use cranberry juice recipe.

**BLUEBERRIES:** These need an acidic soil. If they have that, you have a wonderful berry that may bear fruit the first year and for the next 50, but if they don’t have that soil they will die and that’s all there is to it. St. Lawrence Nurseries offers numerous varieties of half-high blueberries. You can prune blueberries only very lightly. Blueberries don’t really have “canes,” just twigs. In all but the far north, do what judicious cutting you must in late winter. You’ll find lots more resources in ATTRA’s “Organic Blueberry Production” at [www.attra.org/attra-pub/blueberry.html](http://www.attra.org/attra-pub/blueberry.html).

**BLUEBERRY SAUCE** Start with 1 c. blueberries. Put half the blueberries and ½ c. water into a pan. Simmer 3 minutes. Add 1 t. cornstarch and stir thoroughly. Continue cook-

**BLUEBERRY SYRUP** Combine 1 c. fresh (or frozen or canned) blueberries, ½ c. water, and ¼ c. sugar, and bring to a boil. Crush berries. Simmer 2 or 3 minutes more. Serve this syrup hot.

**Drying.** Dry blueberries out of doors 2 sunny days in a row, then in the oven at low heat until they are rubbery and look like raisins.

**CRANBERRIES**

**CRANBERRY JUICE** Cook 1 lb. cranberries in 1 qt. water until soft. Crush and drain through cheesecloth for a nice clear juice.

**CRANBERRY COCKTAIL** Grind 4 c. cranberries in your food chopper. Add 1 c. sugar to 6 c. water. Add the ground cranberries and their juice and boil all for 5 minutes. Cool and strain. Add 1 c. orange juice and the juice of 1 lemon. Chill.

**CRANBERRY ICE** Heat 1 qt. cranberries and 2 c. water together, boiling until the cranberries are soft. Run through a sieve. Add 2 c. brown sugar to puree. Heat again, stirring until the sugar is dissolved. Add the juice of 1 orange. Remove from heat. Cool. Pour into tray and freeze firm. Remove to chilled bowl and beat until light. Return to tray and finish freezing without stirring. Serve at slush stage.

**CRANBERRY KETCHUP** Wash and pick over 2½ lb. cranberries. Cover with vinegar and cook until they burst. Force through a sieve. Add 2½ c. sugar, 1 T. cinnamon, and 1 T. ground cloves. Return to heat and simmer until thick. Pour into hot sterilized jars and seal.

**SWEET CRANBERRY “RAISINS”** Saute cranberries in brown sugar and butter until the skins break. Add a little honey and stir. The secret is the broken skin that allows the sweetness from the brown sugar and honey to get inside the cranberry. Then dehydrate. It takes a lot of cranberries to make a little bag of cranberry raisins.

**CURRANTS:** This small fruit went through a time of trouble in the 1920s when bushes were uprooted and became very rare as a result. Certain varieties of currants and gooseberries were supposed to carry white-pine blister rust, a disease that destroyed white pine trees. Many states passed laws banning currants and gooseberries, and seed catalogs stopped carrying them. Now currants are making a comeback. Legal restrictions on them are being lifted, and increasing numbers of nurseries are carrying them again.

**CURRANTS:***
That's good news, because currants and gooseberries are among the hardiest of the berries and are important to folks who live on mountainsides. Currants are a firm berry as compared to the blackberry. They are easy to propagate by stem cuttings, and I know people who have raised them from seed. Take cuttings about 8 inches long anytime during the fall, winter, or very early spring. They won't do quite as well if you start them after growth has got going in the spring. They do well in a clay soil. It's still a good idea not to plant currants if there are white pines (pines with needles growing in clusters of 5) within 300 yards. And check your local laws to make sure you aren't in an area where it's still illegal to plant them.

**Drying.** Put your currants into a large bowl and add some flour (about 1/2 c. per 1 lb. of currants). Mix the flour with the currants and then rub the currants between your hands to get the stems off. After the stems are off, put the currants in a colander and let water stream through them until you have nothing left but currants. Then scald them a half minute, and chill by drenching again with cold water. Drain. Spread on pie dishes, trays, and so on, and put out in the sun or on your screen or into the oven to dry. They are like little raisins when done.

**CURRANT JUICE** Choose fully ripe, bright red currants. Wash in cold water and remove stems. Crush the currants and warm to 165°F to start the flow of juice. Don't boil. Press the hot fruit in a jelly bag to extract juice. Sweeten to taste.

**BLACK CURRANT PUNCH** To each cup of currant juice add 2 c. weak green tea. Sweeten to taste. Serve in glasses half filled with chopped ice and garnish with a sprig of mint.

**CURRANT SYRUP** Boil 3 c. sugar with 4 c. water until the sugar is dissolved, then add 4 c. cooked, strained currant juice and the juice of 6 lemons. Cool and bottle. This is nice to add color to other drinks.

**CURRANT KETCHUP** Combine 4 lb. ripe currants, 2 c. vinegar, 1 T. cinnamon, 1 T. salt, 3/4 c. sugar, 1 T. cloves, and 1 T. pepper. Mix, boil down to a thick sauce, and bottle.

**GOOSEBERRIES:** These went through the same thing as currants and became very uncommon. Berry gooseberries grow on a low berry-type bush. For "Chinese gooseberries," see "Kiwi" in the vines section. Regular gooseberries are another tiny berry-type fruit.

**Harvesting.** When gooseberries are green they are still unripe. They turn kind of purple red at the moment of ripeness. There is a wide variety of sizes, from tiny on up. In my experience they either have to be picked before the berries get too ripe or you have to cope with worms in them. It's the same as with peas. The insects "sting" them—make black spots on the outside, which, if left long enough, hatch into worms. If you have a sturdy stomach you can use the wormy gooseberries. I set them on to cook in plenty of water. As the berries heat, the worms rise to the top and can be skimmed off.

**GOOSEBERRY SAUCE** Stew 1/2 lb. gooseberries in 1/2 c. water until soft. Rub through a sieve. Return to pan. Add sweetening to taste and 1 T. butter if you are planning to serve it as a relish with roast goose, duck, or mutton.

**GOOSEBERRY FOOL** Simmer green gooseberries, starting with cold water, until tender, adding a little salt (optional) to preserve the color. Strain and puree. Put the puree on the heat with sugar to taste and cook until sugar is dissolved. To serve, mix with cream.

**GOOSEBERRY JAM** Cook 4 1/2 c. gooseberries in 2 T. water over medium low heat until yellow. Add 2 c. sugar. Bring to a boil again and boil 5 minutes. Pour in jars and seal. You'll get 2 pt. jam.

**GOOSEBERRY PIE** Cook. 3 c. fresh gooseberries just long enough so they pop. Add 1/2 c. sugar, 1/2 t. ground nutmeg, and 4 T. flour. Pour onto a prepared unbaked pie crust. Put second crust on and seal well to keep from boiling over. Put slits on top. Brush top with cream and sprinkle sugar on it. Bake about 45 minutes at 425°F; or until it looks cooked. Good with plain cream.

**HUCKLEBERRIES:** These are cousins of the blueberry—a small, firm berry.

**Canning.** These can nicely. Use basic canned berry recipe. If you can huckleberries, make sure your jars are sealed and you wash the outsides because they tend to give off an odor that other foods pick up.

**BASIC HUCKLEBERRY SAUCE** You'll need 1 c. huckleberries, 1/4 c. sugar, 1 t. water, 1 T. light corn syrup, 2 T. berry juice, 1 T. cornstarch, and 1 T. lemon juice. Place berries in a pan. Add sugar, water, and corn syrup. Bring to a boil. Blend berry juice and cornstarch and add to berries, stirring constantly. Cook until thickened. Stir in lemon juice and remove from heat. Chill. Good for jelly roll, open-face pie, cooked pie shell, or topping for ice cream.

**HUCKLEBERRY PIE** Make dough for a 2-crust pie. Boil, drain, and rinse 2 c. huckleberries, then cook again with a very little water until tender. Add sweetening to taste and 2 T. flour. Bake in a 425°F oven.

**HUCKLEBERRY CAKE** Barbara Stone, Stites, ID, wrote me: "I don't care for huckleberries raw but in a cake is something else. Separate 3 eggs. Beat the whites until stiff and set aside. Beat the egg yolks and blend with 1/4 cup milk. Blend in 1 cup sugar and 1/2 cup butter or other shortening. Sift 1/4 cups flour with 1 teaspoon baking powder, 1/4 t. nutmeg, 3/4 t. cinnamon and add to egg yolk mixture. The batter will be unusually stiff. Put berries into flat dish and roll in flour. Up to this point an electric beater can be used, but now the berries are folded into the batter with a spoon. Then fold in the beaten egg whites. Bake in a greased and floured [8-inch square] pan. A loaf pan is better so the batter doesn't spread too thin. Sprinkle the entire top of the cake with a thin coating of sugar. This will form a glaze. No frosting is necessary. Bake in a moderate oven (350°F) until done. Depending on the oven it usually takes 50–60 minutes."

**SALAL:** This Pacific Coast native, Gaultheria shallon, is an evergreen shrub, 2–6 feet high, and can thrive in either sun or shade. It can grow from mid-California to British Columbia. It needs moist soil.

**Planting.** Plant seeds, cuttings, or divisions. You can get plants from Raintree Nursery, 391 Butts Rd, Morton, WA 98356.

**Harvesting.** Pick the small bluish-black berries in the fall when the whole cluster has finished ripening. You can substitute in any blueberry recipe or use to make a jelly.
**SALAL JELLY** You'll need 1 c. salal juice, 1 c. tart apple juice, and 1 c. sugar. (See “Jelly-Making” in Chapter 7.)

**SARVIS BERRIES OR SASKATOON BERRIES:** Eaten fresh, these are bland and flavorless, but put them in pancakes. When the heat hits them, the flavor comes out. Or use them as a filler with other berries. Or add lots of grated orange and orange juice to add flavor.

**STRAWBERRIES:** These plants want lots of moisture and a sort of shady location, like on the shady side of your house or under an orchard. Next edition I’m going to say more about them, but no time now. Krohne Plant Farms is a mail-order strawberry specialist: 616-424-5423; fax 616-424-3120, 65295 CR 342, Hartford, MI 49057. If you’re interested in growing them for sale, you’ll find much more info in “Strawberries: Organic and IPM Options” at www.attra.org/attra-pub/strawberry.html.

Preserving. Imogene says, “Just let them boil up once, then pour into jars and seal.” That’s Imogene’s way and she cans umpteen quarts every summer. To can strawberries the regular way, pack them hot, cover with hot juice, and process 15 minutes. I freeze them. Dried strawberries are delicious tasting, despite the fact that they turn very dark and look terrible.

**STRAWBERRY JUICE** Use fully ripe berries. Wash in cold water. Drain. Remove anything green. Crush and strain the juice through a jelly bag.

**STRAWBERRY PUNCH** Mash 1 qt. strawberries. Add the juice of 1 lemon, 2 T. orange juice, and 6 c. water; and let the mixture stand 3 hours. Strain. Sweeten to taste. Serve with ice.

**STRAWBERRY-PINEAPPLE JUICE** Combine 2 c. strawberry juice, 1 c. pineapple juice, 4 c. water, ½ c. lemon juice, and ½ c. honey. Mix well and serve with ice.

**OVERNIGHT STRAWBERRY PRESERVES** Wash and hull firm, choice berries. Combine 2 c. sugar and water and boil until you can spin a thread when you hold a spoon up that has been dipped into the liquid. Now gently add 4 c. strawberries, ¼ c. lemon juice, and 2 c. more sugar. Boil 12 minutes without stirring. If you get a scum, skim it off. Pour the mixture out into a shallow pan and let set 24 hours. Put into jars cold and seal with paraffin. The berries keep their shape and color.

**MODERN PRESERVES** Prepare 4 half-pint jars. Heat 1 c. of your juice to boiling. Then pour it over ¼ c. fresh herb (or 1½ T. dried herb) or 2 T. whole spice. Let soak for half hour. Strain it into a nonaluminum pan. Add 2 c. more of juice, 2 T. vinegar, and 3 c. sugar, mix, and boil (stirring constantly). Now mix in ½ bottle pectin, and boil another minute, still stirring. Remove from heat, and stir in food coloring at this point if you want it. Pour immediately into sterilized jelly glasses. Adjust lids. Process 5 minutes.

**OLD-TIME PRESERVES** Prepare jars to hold 10 cups. Coarsely chop 6 lb. tart apples, put into nonaluminum pan, add just enough water to cover, and cook a half an hour, or to softness. Then pour into jelly bag over bowl and let it drain overnight. Next day, measure the juice. Per 2¼ c. juice, add 2 c. sugar. Stir sugar into solution over low heat. Add herbs or spices, or a mixture of them, tied into a porous bag, and simmer until jelling point is reached. Remove bag and pour into jars.

**STRAWBERRY SHERBET** Soften 1 envelope unflavored gelatin in 1 c. orange juice in a small pan. Combine 1 qt. washed, hulled, and crushed strawberries with ½ c. sugar, and then stir in gelatin-orange-juice mixture. Pour into your freezer tray. Freeze, stirring once or twice, until almost firm. Remove to chilled bowl, break up with a fork and then beat until smooth but not melted. Fold in 2 stiffly beaten egg whites, blend, and return to refrigerator. Freeze, stirring once in a while with a fork, until firm.

**Wood Heat**

**Managing an Existing Stand of Trees**

If you are starting your forest or orchard management career with an existing stand of trees, the first thing to do is to get acquainted with them. What kind are they? What are their uses? You may choose to leave them exactly as is. Or, to do some tree weeding, taking out some in order to replace them with more needed ones, yet retaining a mixture of trees for many different purposes and products. Or you may want to take the existing trees out and start over, specializing and growing a plantation of all the same kind of tree. When you are planting a tree crop, you’re usually planting for a maturity date or a market year one or more decades away, so think long-term.

Horse logging does the least environmental damage to big tracts. Read Work Horse Tales: Adventures in the Forests of Appalachia, by Anita G. Mannon, for glimpses of the life-style of folks working with draft horse partners in the forests of the Blue Ridge Mountains today: 888-795-4274; PO Box 689, Floyd, VA 24091; www.xlibris.com/bookstore.

**Reforestation**

You don't have to prepare the soil by cultivation to plant forest-type trees. If trees are planted 5 feet apart (right for a 6-foot-high tree), you can grow 1,000–1,300 per acre. Each tree needs sunlight to live, so plant in the open spots. Two people can plant a huge number of trees in just a single long, hard-working day, using no more equipment than a spade. (There is such a thing, however, as a mechanical tree planter.) But don't expect all of them to survive; a
percentage won’t make it and will need to be replaced (maybe up to 30 percent, but probably much less).

**Mulch Collars:** You can raise the survival rate dramatically (up to 90 percent) by installing a heavy cardboard circle (available from printing-press shops) at least 36 inches in diameter, with a center cut out plenty wide for the tree, around the tree base. Or make a mulch out of newspaper or weed-block mats. But the heavy cardboard circles do the best job of protecting seedlings from competition from weeds and brush. Just make sure that what you install isn’t in a position to girdle the tree (cut a seedling hole in the middle), is of a material that will eventually decompose (cardboard or paper), and has a system to let water through (cut slots for that). The mulch mat must be anchored using wood slash or rocks heavy enough to keep it from blowing off or slipping over on top of the baby tree. If the mulch protection lasts 3 years, by the fourth the tree is usually far enough developed to survive no matter what. Shaded lower branches may wither, die, and eventually fall off. That’s okay. Actually, a long “clean” trunk is desirable for lumber.

**Woodlot Growing Information:** To grow enough wood to stay even with the appetite of a wood-burning stove is a grand achievement in itself. For more help, read *The Earth Manual* by Malcolm Margolin, an inspiring book about how to work with wild land without taming it. It covers tree-felling, tree-doctoring (why not to), erosion control, seed collecting and planting, pruning, etc. You can order the pamphlets “Woodlot Management” and “Fast-Growing Firewood” from Storey’s, 802-823-5810; www.storey.com. Working with Your Woodlot by Mollie Beattie, Lynn Levine, and Charles Thompson covers hardwood forests in the northern U.S. and mountainous South.

**Growing Christmas Trees or Timber Evergreens:** If you don’t need pasture and your land is on the poor side but still gets enough rainfall or can be irrigated for evergreens, a market option is to plant Christmas trees. They’ll grow on cool, north-facing hillsides that fruit trees might not do so well on. They’ll be harvested while still reasonably small so no big equipment is necessary. And your investment can be quite reasonable. Plan to space your planting 5 feet apart for a 6-7-foot harvest size. If you will harvest smaller, plant closer.) To make more efficient use of your space, plant small trees between each pair of large trees 2 years before harvest time for the big ones.

**Gathering Tree Seed:** You can gather cones, dry them, shake the seeds out, freeze them for conditioning, plant in seedling pots, then transplant them when they’re bigger. Or you can plant seedlings . . .

**Collecting Seedlings:** You could collect these from forests (but don’t steal). Gather in early spring when they are 5–15 inches high. Dig or pull out (only when the ground is very moist), being careful to preserve their root system. Bundle, transport, and replant in your field. It’s best if you can pull and replant them in the same day. You may want to save space and grow them for a couple years in a nursery bed before setting them out in the field.

**Nursery Seedlings:** Or you can buy seedlings from a nursery. Buy locally if possible, or from a nursery in your same climate zone. Trees grown in a warmer climate than yours will tend to start growing in the spring by their old calendar rather than your new one and possibly be killed by frosts. To buy seedlings, learn what kind of trees are available, how much they cost, and how many years they’ve grown in the seed bed and then in the transplant bed. Some states have tree nurseries and sell seedlings reasonably from them. (A state extension agent can inform you on this.) Here are nurseries that specialize in woody seedling trees:

- **Carino Nurseries** specializes in seedling Christmas trees and other evergreens: 800-223-7075; fax 412-463-3050; Box 538, Indiana, PA 15701.
- **Muser Forests:** 800-643-8319; fax 724-463-9893; PO Box 340, Indiana, PA 15701-0340.
- **Pikes Peak Nurseries:** 412-463-7747; R.D. 1, Box 75, Penn Run, PA 15765.

Why they’re all in Pennsylvania is a mystery to me.

**Harvesting Wood**

Foresters harvest trees for their wood before they become over-mature or die. Plain folks find good uses for dead wood in the stove. Either way, every block of wood represents a concentration of sunlight’s energy ready to be released by fire.

February is an awful time to be out scouting for wood. The wood is best gotten during the fine dry days of midsummer and early fall. Old-timers say that if you fell the tree while the sap is still in the leaves, the trunk will be dryer and easier to cut.

**Finding Your Wood.** Any tree is owned by somebody—a rancher, a homesteader, a corporation, or a government agency and, by extension, the public. Anywhere outside your own property, you need permission before you cut firewood. The U.S. Forest Service and the Bureau of Land Management look after a lot of the public woods and will, in many areas, readily grant you a permit to cut 10 cords or so, if you give them $10. You can get your permit at any Forest Service District Office or at any B.L.M. office. Some states (e.g., Montana) will give you a free permit to cut firewood on land managed by them. Be sure you know exactly where the state-owned trees are before cutting it. To cut wood on privately owned land, ask permission first. Owners can become very angry, and justifiably so, if you enter and cut without permission. That’s trespassing and theft. If you can’t find the owner, leave the wood alone. Large corporate landowners often offer paid permits available at the corporations’ offices. There will be a strict set of guidelines you must follow when cutting their wood.

**Choosing the Tree.** Every variety of tree is different. They look different and are of differing hardness, burning style, sawing and splitting quality, even aroma in the forest and in the fire. Softwoods, such as pine and cedar, have a coarse fiber that burns quickly. They make good kindling. Pine is very pitchy. You can tell a pitchy wood in the fire because it does a lot of noisy popping. For a long-term steady fire, especially for oven-baking, hardwood (or coal) are nicest. It really depends on what trees are available to you. Some woods provide you with beech, yellow-birch, maple, and black-cherry, and those all make fine wood, too. Another consideration might be ease of sawing if you’re working by handsaw rather than chain saw. Balsam is especially hard to hand-saw. Yellow birch takes less effort to saw than maple. Or consider ease of splitting; maple splits cleaner than the birch. Or whether it will burn green or has to be well dried; yellow birch will burn green.
Tree felling is dangerous if you aren't experienced, so proceed cautiously. First find the one you want. Standing dead tamarack, red fir, or black pine are the best in this part of the country. White and yellow pine are fairly good. Cedar's good for a hot quick fire to set off harder woods but it doesn't last. Bull pine, white fir, or any spruce are not very good firewood but will do if you can't find anything else. It's ideal to find a snag (dead tree) that still has bark and branches on it. The bark and branches show that it hasn't been dead too long and hasn't had time to rot. Or a blow-down with bark and branches will be all right if it's not too wet. Use green wood (live wood) only if you have cut it and let it season at least 6 months to dry out well.

**Chain Saws.** To cut down a tree it's most convenient to use a chain saw. You can do it with an ax, but if your tree is big enough to bother cutting down at all that's a pretty big struggle. A 12-inch chain saw is cheaper, lighter, and easier to handle than a 16-inch one, but it won't cut as big a tree. In general, a chain saw can handle a tree with a diameter almost twice the length of its blade, though if you really know what you're doing you can stretch that. You've got to oil it all the time you're sawing by a squirt attachment. You get a round file that is the same size as the teeth on your saw and file them sharp between sawings. The rakers on the chain also have to be filed down regularly. Different wood conditions require different heights for the rakers. Sawing frozen wood is different, too.

![Diagram](image)

You need a manual or somebody who knows what he's doing to help you get started with a chain saw. Hang on to your chain-saw warranty. They break down a lot, especially the cheaper brands. The big ones are used by sawyers who are felling trees on a professional scale. The chain saw runs on a gasoline motor. Once in a while you can get a new one won't wear you out near as fast. For more information, see your chain-saw warranty. They break down a lot, especially

**Bucking.** Once the tree is on the ground you can finish wherever you want to. First you take off the limbs—"limb" it. Sawing it up into chopping-size segments is the next step, and that's called "bucking." If you have a big logging truck you can load the whole log up and take it home, or you can saw it up on the spot and take chunks home. Know how long a piece your stove takes (a little shorter than the length of the firebox). That's how long your segments should be. You can buck with a roaring chain saw and it'll be done in a jiff. Or you can do it with an old-time 2-man crosscut saw together with a friend, spend a little more time, and have a pleasant conversation while you work. The rhythm of working with a 2-man crosscut saw is something you learn with experience. After the bucking, folks usually leave the chunks in a big heap to dry some more before chopping.

**Chopping.** Before the wood is stove-ready, the segments have to be split with an ax—double-bladed or single. Save a couple of blocks of really good hard wood with wide diameter to be chopping blocks. They're indispensable for woodworking and for slaughtering poultry, too, if you do it the old-time way. Maybe taking such an interest in ax technique is unwomanly; I don't have to chop wood now much, thank heavens—there's plenty else. But I was the only kid at home all my adolescence, and I chopped it aplenty for my mother (as well as hauled water by the bucketful up the creek bank to keep the porch tank full).

**Chopping Safety.** Strive for accuracy before you strive for force—at least enough so that you don't hit your foot. Then, once you're sure you can put the blade onto the wood, you want to give it all the power you can. Use a good big ax, a heavy one, because you can get a lot more force with it. Wear heavy boots in case you miss. Chips can fly up into an eye or the ax blade can hit a knot and be deflected, so don't let children, or anybody, stand near when...
you're chopping. My little boy got an ax blade in his forehead when he got too close behind another boy who was chopping. No harm remains than a little scar, but it's a lesson. If you want to be really safe, wear goggles, a hard hat, and steel-toed boots!

Chopping Technique. Everybody's got his or her own way of chopping. A friend of ours only lifts the ax to shoulder height, then brings it down with a big grunt and the wood splits. Another friend raises it straight over his head. Mike holds the ax strong in his left hand, loose in his right hand, and then brings it down kind of pulling with the left hand and pushing with the right hand. The best stroke for me uses both hands on the ax—as if you were holding a baseball bat, only farther apart. To do it my way, if you're right-handed, start the ax out back of your right shoulder behind your head with your back arched backwards just a trifle (or you can alternate shoulders with every swing) and then bring it forward and down, moving your shoulder and chest forward at the same time.

Try to hit your block of wood right in the center. Mike says you don't want the ax absolutely perpendicular to the stump when it strikes. I aim to get it square on. If your wood doesn't split from the center you can try taking slabs off the edge awhile before you tackle the heart. If you can get your ax into the tree but not out the other side, pull it out and try again. Look for a natural crack to strike into. There usually is one in old wood. If you're still finding it hard, use wedges and a wood-splitting maul or sledgehammer instead of the ax.

Knots. A "knot" is where a branch grew out of the trunk. That branch extends like a holding pin all the way through the trunk to the center. It prevents the trunk from splitting naturally. With tamarack or red fir you won't have too much trouble with knots. With cedar they're impossible. Split away from the knot and just throw the knot away unless it's small enough to burn by itself. But big cedar knots are too huge for anything but a bonfire. Cedar blocks make dandy furniture though, so if you see a knot in the block you could just reserve it for a stool or something.

Kindling. Some of the wood has to be split and re-split into very slender sticks called "kindling" for starting fires. You need really dry wood for kindling. Wood on the green side burns okay in a big fire, but it makes terrible kindling because it is so damp. To make kindling out of it you have to split it into small kindling-size sticks and then dry them out some place like in your warming ovens—and then it will work to start a fire.

Kindling is made with a hatchet because those little sticks won't stand up by themselves. You have to hold them up with your left hand and chop up with your right hand using the short-handled hatchet. The thing with using a hatchet is to not cut your fingers off. Either learn unbelievably good aim or learn to let go just before the hatchet blade strikes, so the fingers are out of harm's way. I keep the hatchet back of the wood range, hanging on the wall by its neck—a nail on each side, high out of reach of the children. That's where the other wood-stove implements are kept too.

Wood Storage: Cut and store under shelter inside a shed or at least under a tarp. If you have 2 buildings close together you can roof over the gap with tin sheets or something cheap, put a back on it, and have a very adequate woodshed. Or you can have an open woodpile for the blocks outside somewhere and a large area for drying and storing wood on your porch. I carried wood to our porch from my chopping station in the yard by the woodpile. But we lived in a relatively dry climate. A wet one would need covered outside storage too.

My father always insisted on a very neatly arranged stack of wood inside our front porch. The wood supply on my parents' porch was enough to last about 10 days and was arranged by graduated sizes with the real small kindling on the left end and the wood pieces getting bigger as it moved to the right. That way my mother could easily find whatever size sticks she wanted. Now my husband and I have a similar system: a pile of tree chunks outside by the chopping block, a porch storage area for chopped wood, and a kitchen wood box near the stove. It has to be filled once a day in cold weather. It's 2 1/2 feet wide, 4 feet long, 3 feet high, and bottomless so I can pick it up and sweep up the sawdust come spring. I toss all the paper-type garbage in it in wintertime for starting fires.

The Technology of Wood Storing. Split your wood before stacking; this increases the exposed surface area and reduces drying time. Stacking the wood in alternate directions row by row further helps the drying process. Protect your wood supply from rain and snow by keeping it in a woodshed if possible. That's better than stacking it against the side of the house or under trees in the yard. If you must store wood on the ground, stack at least 6 inches off the ground to protect the lower part of the woodpile from
ground moisture. Simply lay 3 parallel poles under the pile and then set the wood on top of them.

**Sharpening Hand Tools:** It takes practice to master tool-sharpening. Find someone in your area who regularly sharpens tools and watch how it is done. No edge remains sharp after being used. The edge dulls as the metal wears. The sharper the edge to start, the more quickly it wears and the more often you'll have to sharpen if you want to keep such a sharp edge. Corrosion caused by rust or fruit juices also dulls blades. If you cut something acidic (even with stainless steel), it helps preserve your blade's sharpness to wipe the knife dry afterwards.

**Coal:** Bituminous coal doesn't make as hot a fire as anthracite, and it's dirtier and smokier. If you are using coal, it has to be stored where it won't get wet. Coal requires more shelter than wood. To bring the coal to the stove from its storage place in your woodshed, or a corner of the garage or cellar, the coal scuttle (a strong bucket with a wide pouring spout on the end and a bale handle, about as big as what a person can stand to carry) is traditional. Any bucket will do, though. You usually need only a bucket at a time in the kitchen if you're mostly using wood. The coal is to get a hotter fire than wood will give you and a longer-lasting one; you put in the coal the last thing before going to bed. TAMARACK holds a fire about as well, though.

**Burning Wood**

Burning wood seems easy and natural to me. But I live in a timber-producing area, have timber here on the farm, and a sawmill and wood products plant both just down the road. Correspondents tell me that in the East, wood is very scarce and very high-priced, that wood stoves are hard to come by, and that insurance companies won't insure a home that is heated with wood. Anyway, if you haven't got dead trees around then a wood cookstove isn't necessarily right for you.

**Wood Heat References:** I have been urged to position the references at the very end of the topic. I know that's how other people do it, but I prefer to put them right after my introduction to a subject. That's because I believe the references are potentially more important to you than what I have to say. They're written by specialists in the field who have spent years experimenting and gathering information on just a single topic. By putting them up front I'm urging you to start with them and maybe even skip what I have to say, or heavily supplement my material.

**The Economics of Wood Heating:** If you are considering switching to wood heat, calculate your total fuel bill for last year and then figure your bill for next year. If you install a wood stove, how much of your previous fuel do you still expect to use, either for supplemental heat or for uses other than space heating (water heating, cooking)? What do you expect to pay per cord of wood? If you don't know, look in the classified section of the local newspaper. Multiply the price per cord by the number of cords you will need per year. A cord of dried softwood such as pine, larch, or Douglas fir provides about the same amount of heat as 19.3 thousand cubic feet of natural gas, or 5,276 kilowatt hours of electricity. So, if you now heat with gas, divide the number of MCF of natural gas by 19.3 to estimate equivalent cords of wood. If you heat with electricity, divide kwh by 5,276 to estimate equivalent cords of wood.

I've seen numbers suggesting that you might save only, for example, $75 per year by switching from gas to wood if you got your wood for $50 a cord. However, if you are switching from electric heat to wood, your savings might be $700 or more a year. If you cut the wood yourself, you could save even more money. But there would still be expenses involved. Is it your wood? And how far do you have to drive to get to it? On average, you'll spend $12.50 a cord on gasoline for cutting and hauling, plus the wear and tear on your truck and chain saw and you. And don't forget the cost of your wood stove and its installation, and the chimney, and the chimney-cleaning. Some states offer state tax credits for switching to wood, but only if you buy a clean-burning stove that meets their standards.

**Of Wood Burning and Air Pollution:** This is a problem with wood stoves, both for the individual homeowner and for the environment in general. Wood stoves make a considerable contribution to an area's smog if there are lots of them in a small area. Air inversions and still air can keep that pollution hovering right over you. Or your next door neighbor, an elderly asthmatic, may literally be dying from your burning. So, if you want to burn wood, be considerate of others. And if you're in an area with regulations, obey the laws. Oregon regulations began in July 1986 and national standards patterned after Oregon's went into effect in July 1988. The stoves that I've described down below wouldn't pass the emission laws in Oregon.

**Fire Prevention:** How would you cool your fire quickly if a pipe or your box gets red hot and you become worried about a fire? In an emergency you could just pour water on it. On the other hand, that could cause cracking of the stove parts! During the winter months chimney fires in the northern Idaho community of Coeur d'Alene averaged 1 a day between November 1 and January 1. In Coeur d'Alene about half of the homeowners heat with wood. Fires from wood heat devices make up almost 60 percent of the residential fires in the nation. You have to install these devices, use them, and maintain them correctly. Many fire departments will make a courtesy inspection of your wood heater.

**Wood Stove Safety Products.** You might also want to buy a special chimney fire extinguisher and keep it handy. And any wood-heated home needs a smoke detector. The smoke detector will warn you if your stove develops a back draft during the night or if there's a fire out of control. Installing and operating a wood stove in a mobile home requires special vigilance. You can order numerous products that assist in woodstove safety from Lehman Hardware (888-438-5346; www.Lehmans.com), such as Soot Destroyer, a stove and stovepipe thermometer, and a chimney fire extinguisher.
Creosote. The primary danger is creosote, a waste product that collects on the surfaces of the stove and pipes. Anything over ¼-inch thick of creosote build-up is dangerous. Creosote burns at about 2,300°F, hot enough to melt stainless steel. If you simply knock the creosote off the smoke shelf and down into the chimney, you can ruin your catalytic converter. A common problem is buying a stove that's too large for your house size, then letting the fire burn low inside it to save money. One last log smoldering is what makes the chimney thick with creosote. A good way to clean up is once or twice a day, when you first build your fire, let it free burn freely and cook for a few minutes. The intense heat will clean out the pipes. You can also slow down the build-up of creosote by burning only well-seasoned wood, being sure your fire has an adequate supply of oxygen, inspecting your flue often, and cleaning your chimney at least once a year. If you do this yourself, you need a metal brush with a long extension rod, designed for the job. Your stove-dealer can provide these.

Chimney Fires
NOTE: Read this if you see a cherry-red stovepipe and hear the roar of a chimney fire! Shut off the air supply to the stove and get everyone out of the house. Call the fire department. Then use your hose to cool the roof, but don't spray water directly into the chimney. That could result in even more damage, by causing the overheated flue to contract too quickly. Once the fire is out, have the chimney thoroughly cleaned and closely inspected before using it again.

Wood-Stove Shopping: When I first started writing this book, there were no such things as stores specializing in wood stoves. And stove design was traditional and hadn't evolved for a hundred years. Then there was a burst of attention to wood-stove technology coming from alternative energy scientists, and now wonderful stoves are scattered all over the areas where wood is convenient to burn, selling these much improved stoves. The new stoves are cleaner, safer, more efficient, and bewildering in number—some 450 different models to choose from. So many of the modern wood stoves are amazingly high-tech. Some are computerized, many are the result of thousands—tens of thousands—of dollars spent on research and development. They're more efficient: efficient at combustion and efficient at heat transfer capability. You need both kinds of efficiency.

So check in your yellow pages to find stores that specialize in wood-burning stoves and related products. A door/stovepipe/legs kit for a barrel stove is available from Lehman's (888-438-5346) for $59 or $79, and from some hardware stores.

The next cheapest wood stove is a small "outdoor" or "camping" type. It can heat one room. The largest size can heat a house. They usually have flat tops you can cook on. A Chinese import in this category is the Boxwood Heater/Stove, $170: 800-423-2567; international 805-388-3000; toll-free 800-444-3353 or 800-237-4444; www.harborfreight.com. Cabela's, a camping mail-order outlet, offers one brand of this stove type, made in Utah, for $150 to $639 (depending on size); free catalog: 800-237-4444; One Cabela Dr., Sidney, NE 69160; www.cabelas.com.

For nicer stoves, prices go up to $4,000 and anything in between. How about an outdoor wood furnace? Central Boiler Classic is installed away from your home. It has thermostatically controlled heat to a possible several buildings. A water jacket surrounds the furnace firebox, and heated water is pumped to the buildings through insulated underground pipes: 800-248-4681; www.centralboiler.com.

A mail-order wood heat specialist is Vermont Castings: 800-227-8683; CFN Majestic Product Co., 474 Admiral Blvd., Mississauga, Ontario L5T 2N1, CANADA. Or check out Energy House, 3902 S. Main, Salt Lake City, UT 84107; 801-261-3210; 877-440-6481; www.transoceanltd.com. You can find a local dealer for the Norwegian manufactured wood stove, Jotul, at their website: www.jotullame.com. These specialists routinely carry wood-stove accessories, books, and pamphlets, as well as stoves. And they'll give you good advice on what to buy. You need guidance in your wood-stove shopping now because the Environmental Protection Agency has adopted regulations that strictly limit emissions from all wood stoves. Your stove dealer is probably certified by the Hearth Education Association and has worked hard to become knowledgeable on this subject.

Fireplace? A fireplace can make you warm if you're sitting within 6 feet or so of the heated space, but it's not an efficient way to heat the entire room. A fireplace can be modified with fireplace screens and tabular grates or fireplace inserts or stove-like inserts to improve its efficiency.

Stove Material Choices. You'll buy a stove made of cast iron, plate steel, or sheet metal (or even soapstone or porcelain). In general, the thicker the metal, the more it costs, but the longer the stove will last. Plate steel and cast iron are about equal in their heat retention ability and cost about the same. A sheet metal stove is cheaper, but will burn out faster and need to be replaced sooner than a heavier one. A sheet metal stove with reinforcement from firebrick or metal plates in the firebox will last longer than one without.

Stove Designs. Radiant stoves have a single-walled firebox. These stoves heat by simply radiating the heat out into the room. A convection stove has a firebox to contain the fire and another metal layer surrounding the firebox, with an air space in between. This stove heats by circulating the air from this space, thus heating the room with warm air. There may be an electric fan to circulate the heat away from the stove. You can position a circulating stove at about half the distance from combustible materials as that required for the radiants.

Some think that wood-pellet stoves are the wave of the future as wood gets scarcer and more expensive and air-quality regulations on emissions of wood-burning stoves increase. Pellets burn cleaner, and there are special stoves designed for them such as Welenco. A ton of pellets costs about $125 and will last 6–8 weeks of average winter weather. Pellets are made not only from wood, but also from corn, walnut, and almond shells.

Catalytic Combustor. This isn't a wood stove but is used to increase the overall efficiency (it can help up to 20 percent) of almost any wood stove it's attached to. But the combustor is a rather fragile item and not cheap. Also you'll have to be careful not to burn anything but wood in your stove, since the lead found in nails and in the newsprint on magazines and newspapers can destroy the converter.

You are likely to need professional help installing one of these sophisticated stoves.

Wood Stoves and Air Pollution: Anytime you burn something, you're putting more carbon dioxide into the atmosphere, exacerbating the Greenhouse Effect. Wood fires also produce dozens of different gases, particles, and
other airborne odds and ends, many of which, if inhaled too much, are even carcinogenic. Cigarette smoke and wood smoke are identical in many ways. The wood-smoke particles are small enough to get deep into your lungs and accumulate there, aggravating asthma and bronchitis, making you cough, or giving you a sore throat, runny nose, or headache. A hot, clean fire produces some pollution; every wood stove—even the airtights—let some pollutants escape into your house. If you have a chronic heart or lung problem of any sort, wood-heating can be a health problem. From that point of view, solar, geothermal, wind, and hydroelectric are the winners of the clean-energy-source contest. Ah, if only more of us individual home-owners could be users of them—and not of environmentally damaging energy sources.

Of Wood Cookstoves

I remember the wood stove we had when I was a little girl. It was our only heat and a much-appreciated presence on winter days. Mother raised bread behind the stovepipe. The spring chickens first lived in a box on the floor back of the stove before they graduated to the bathtub. Hot water came from a tank attached to the right-hand side of it with a circulating pipe rigged up to pass near the firebox. I started out cold mornings sitting on top of the stove. As it got warmer I scooched away from the firebox. Then I leaned on the stove. When it got hot enough so I couldn’t lean on it anymore I was thawed out enough to function anyway. I never could understand how my mother managed to get up in that icy house leaving my father and me in our warm beds and make the fire. Now I understand better. Necessity is the progenitor of toughness. I mean, when you have to, you can.

Now I have an electric stove and 2 old-fashioned wood ranges in my kitchen. I use my younger Montag Duchess white-enameled stove in winter as a cupboard and the top as a work area. In summer it moves to the backyard under a canopy to be my canning stove. I like to bake in the electric stove, and it’s a blessing on hot summer days because I can cook a meal on it without heating up the kitchen too much. But I prefer the wood stove for frying, stewing, such delicate businesses as making cottage cheese and cream cheese, and for its friendly and practical warmth on cold days since it heats the kitchen area. That stove is a big black box with the name “Monarch” on it in 9 places, warming ovens on top, and lots of fancy metalwork. It’s a good stove too.

Installing a Stove: The old-style wood-and-coal range is a large iron box, which may or may not be on legs. It should be placed well enough out from the wall not to be a fire hazard and set on a fire-retardant sheet to protect your wooden floor. Stove pipes need to be assembled carefully and cleaned regularly. Chimneys must be insulated properly. A spark arrestor on top of the chimney will protect your roof. You may be concerned about how to keep squirrels and birds out of a fireplace chimney and about creosote build-up.

Leveling a Stove. When you first set up a wood cookstove it’s important to get it level. Put a frying pan on top with a few drops of water in it for an indicator. The drops of water should go to the center of the pan.

Getting Acquainted with Your Stove: The firebox is usually on the left. At the bottom of the burning area is a movable grate—an iron grill with interlocking fingers—which is opened by a special handle to let ashes fall down into the ash pan, a trap that occupies the lowest level under the firebox. You can keep the grate shaker hung near the stove along with the scraper, poker, pot holders, hatchet, and lid lifter. The poker is a long metal rod with a handle used to move chunks of wood away from the sides of the firebox, or to do whatever poking you need to in the fire without burning your hand.

About Dampers and Drafts: In addition to fuel, fires have to have oxygen to burn. The range is connected with the chimney vent by means of the stovepipe. There is a damper in the pipe and probably another at the front of the grate and another at the back or side of the firebox. Technically, the ones that are above the fire are “dampers,” the ones in front of it are “drafts.” The dampers and drafts are used to control the amount of air flow. A new fire needs lots of air. The 2 lower dampers are probably shifted by metal handles to open or close air holes into the firebox. The stovepipe damper is a plate just the diameter of the pipe with an outside handle. It may be adjusted to obstruct the pipe and slow (dampen) the fire by limiting the airflow (draft). The “flue” is the hole inside the chimney or stovepipe through which your draft flows. If you let your fire get big and roaring a little bit before you damp down, it will help burn up and blow out the cinders in the stove and stovepipe that can’t be reached so easily any other way.

Of Stoves, Air, and Weatherization. No matter what you burn for heat, you’ll save money and the environment if you burn less, and you’ll burn less if you insulate your house. Find out where you’re losing heat and try to stop those leaks. Drafts are a major culprit. You can buy a helpful pamphlet (“Cut Those Energy Bills”) from Storey’s or Vermont Castings. But don’t cut off your oxygen supply completely! Keep in mind that if your house is very tightly sealed, there may not be enough natural leakage into it to provide adequate air for your stove. That would result in a weak draft, smoking, difficult starting, and poor performance. (Test to see if cracking open a nearby window solves the problem.)

Here’s another problem with weatherization in a wood-stove-heated home: in a home that is just leaky enough to provide a good, fresh draft for the stove and a
frequent exchange of room air, the pollutants that leak from the stove can't stay around long enough to concentrate in the room air. But as you tighten your house against drafts, air exchange from outside air happens less often; indoor pollutants have time to accumulate, and this can be a health problem. Not all the pollutants—notably carbon monoxide—can be smelled or seen. So, if you are burning wood, the room where you keep your stove has to have a conscious system to vent and renew the air with an air-intake system that will feed your fire with outside air instead of recirculated room air. And always burn a hot, clean fire to minimize the amount of pollutants produced in the first place.

**Starting a Fire:** On very cold mornings, if there is no other heat, I let the children build the fire. It keeps them occupied while the house is warming up. Otherwise, they just stand around the cold stove and complain. The basic idea is this: You strike a match to get heat enough to light paper, which will burn and create heat enough to light kindling, which will burn and create heat enough to ignite bigger, and then bigger, hunks of wood, which will burn with enough heat to kindle coal. That's because each thing has its "kindling point," meaning the lowest possible temperature at which it will catch on fire. So you start with the thing that has the lowest kindling point (the match) and work your way up.

**Starting Clean.** Before starting a new fire, you first need to clean out the ashes from the previous day's burning. Shake the grate with the shaker to get all the old cold ashes down into the ash pan. Take the pan out and empty it onto the garden or into the lye barrel, compost heap, or garbage. If you were using coal yesterday, be thrifty and pick out any half-burned chunks to save and finishing burning later. Having all those old ashes out helps the new fire get air. Besides if you don't empty your ash pan now it will be overflowing by noon with ashes and hot cinders. Then you will have to empty it and the tray will be burning hot and very unwieldy to carry anywhere.

**Laying Burnables into the Stove.** Separate sheets of newspaper. Wad them up individually and put them into the firebox. Or use any discarded papers or paper containers. Add some of your most finely cut kindling on top of the paper, then a few bigger chunks of wood on top of that, then a couple of yet larger sticks on top of that. Arrange all the wood in as open a style as possible, not pressed together so that lots of air can get in there. Not only does the fire in general need air, but at first every individual stick needs an air supply. I carefully arrange them log cabin or teepee style to ensure this. Once it gets going you needn't be so particular. And start with plenty of sticks. One stick of wood never burns well alone. (There's some profound philosophy there if I ever get time to ponder it—a sermon even.) Now light the paper with a match as near the bottom as you can.

**Adjusting the Dampers.** Fire travels up. Always start your fire with all the dampers wide open. As the fire gets going, keep it supplied with fuel of the appropriate size for the stage it's at. As it gets going better you can gradually cut back on the draft. You will waste fuel and have a hard time heating your stove and oven if you let all your hot air go directly up the chimney, which is what it will do with all the dampers left open. So when your fire is going really well, cut back the draft—by turning the damper in the stovepipe—until it starts smoking. Then turn it back enough so you have no smoke. If the chimney damper is shut too tight, you'll have smoke all over the place. If it's open too wide, the fire will roar and consume like crazy—but it won't make the room warm. Close the damper at the back or to the side of the firebox, shut or almost shut. Adjust your front damper to the point that the fire's health seems to require. The hotter your fire the more dampering it can stand. If your fire is too slow, give it more air. If your fire still isn't burning well, try loosening up the pile of fuel.

**Cooking on a Wood Stove**

**Shopping for a Wood Stove's Needs.** Lehman's carries an excellent line of wood-stove items: cast iron (enamel-lined) or stainless steel tea kettles, enameled frontier coffee-makers, old-time flat irons that heat on the stovetop, poker, lid lifters, scrapers, lids, books... and stoves themselves; 888-438-5346, www.Lehmans.com.

**The Top of the Stove.** The oven of a wood stove is hard to work with but the top more than makes up for it. The heat on top of a wood stove is more even and potentially milder than that on an electric or gas stove. You will be delighted with your fried eggs because the texture of eggs cooked alone or in mixtures is directly affected by the temperature at which they are cooked. Cooked below the boiling point of water the egg white is firm but tender, and the egg yolk is tender and like a salve. Eggs cooked at too high a temperature are first tough, then leathery, then crispy. Fry your eggs in a little butter in a cast-iron pan on the right-hand side of the wood range.

---

It's basic knowledge that the different parts of the stove top have different temperatures. The hottest area is usually just to the right of the firebox. (If the draft isn't good, the hottest may be right over the firebox.) You can adjust your cooking temperature just by moving the pan to a suitable place on the stove top. Start it boiling over the hot part, then settle it down to the rate you like by moving it over some distance to the right. The far right is the traditional place for making cottage cheese and keeping dishes warm when a meal is waiting for the eaters.

**Pot Handles and Holders.** This kind of stove is hard on perishable pot handles—wooden or plastic ones. The stove top is hot all around the pan as well as under it and a wooden handle such as that on a coffeepot may even catch
fire. The traditional handles are metal and you pick them up with a pot holder. You can make a pot holder by folding an old washrag in half and the folding it in half again and sewing down all around the edges. Or you can sew down enough layers of cotton rags to get a manageable thickness and then attach a loop to hang it up by. It can be round or square, about 7 inches across is nice. Crocheted ones burn you through the holes unless they have an extra cloth filling or you use them several at a time stacked like pancakes. Keep the pot holders hanging on nails handy to your stoves. You'll be using them a lot.

Stirring on a Wood Stove Top. You need long-handled wooden spoons. You can use a clean stick if you haven't wooden spoons. Wood doesn't conduct heat. The long handle helps you keep your arm away from the heat. Any metal spoon will quickly heat up and burn your fingers. Then you'll drop it in the pot. The old-fashioned iron griddles, waffle pans, and other "hot air" pans—including the kugelhupf (apple-dumpling pan)—are meant to be put right on the hot range top. (If you want to use these pans on an electric burner, put a metal pie pan over the burner—otherwise they'll get too hot in one spot.)

# WHEAT LEPSE
This Scandinavian dish was traditionally baked right on top of a wood range although you can use a pancake griddle. Boil 5 large, peeled potatoes, then mash them and add 1/3 cup milk. Butter and 1 t. salt. Beat until the mixture is fluffy. After it has cooled, add enough flour to roll out thinly, as for pie crust, or even thinner, using your rolling pin. Start with walnut-sized balls. Roll out to tortilla-sized pancakes. Use the center panel of the stove or you can bake on a grill or in a heavy skillet. Clean and oil it and then bake there, turning as often as you need to keep from scorching. If your oven is too cool, stoke up the fire with more fuel. If the oven is too hot, leave the door open a crack and ease up on feeding the fire. If one side is obviously getting more heat than the others, the oven is hotter there and you will need to rotate your baking pan occasionally during the baking. If you have several pans in the oven, rotate them all to take turns in the hot spot. If the top is browning too fast, cover it with greased or wetted brown paper or aluminum foil. You can put a whole pie into a paper bag. Old-fashioned cast-iron frying pans, Dutch ovens, and gem (iron muffin) pans are helpful, since the cast-iron absorbs heat and distributes it evenly throughout the surface of the pan.

Wood Cookstove Repair: Assuming you don't lose a lid lifter, or, worst yet, one of your stove-top lids, the first problem likely to come up is that the stove liner (the firebrick material that lines the inside of the firebox and protects the metal) will first crack and then gradually crumble away. This takes years, but it eventually happens.

I didn't know how you could replace these worn-out firebox parts. Barbara Ingram told me of a way to relin any stove that has a firebrick-type liner using something called "refractory cement." Buy a can of it and a small putty knife. Apply a very thin layer to the part to be relined. Let it dry a while, the lining of the firebox cracked. We tried plain cement made with just sand and it has lasted beautifully. I'm not sure I would recommend this, though. Barbara suggested that you should use a can of it and a little putty knife. Apply a very thin layer to the part to be relined. Let it dry until hard. Then apply another very thin coat. Keep it up until that area is built up to match the rest. Refractory cement will resist temperatures up to 8,500°F and is the stuff they use in blast furnaces. Kaya Morrison, Mount Airy, MD, shared her experience too. "After using our wood stove a while, the lining of the firebox cracked. We tried plain cement made with just sand and it has lasted beautifully and was easy to do."

Karen Prahrl, Washington Island, WI ("an island 7 miles out in Lake Michigan off the NE tip of Wisconsin"), says: "Some brick and block companies sell a dry powder mix that, when mixed with water, can be used to lay a liner to protect the metal surfaces. We have not had a chance to pursue this item and see how it works."

Now that's really putting our heads together!

I wrote the above paragraphs 20 years ago. Now (2002), you can go to your local wood-stove store. Or mail-order furnace cement, firebox inserts, or obsolete stove parts from Lehman's (888-438-5346; www.lehman's.com) or The Cumberland General Store (#1 Highway 68, Crossville, TN 35855; $4 for their 289-pg catalog: 800-334-4640; fax 931-456-1211; www.cumberlandgeneral.com).
Of Green Leaves, Courage, and Foolishness

In my front yard, outside my front door, there's a foolish little almond tree. Perhaps it's appropriate—this foolish little almond tree living outside my door. Because this is the same winter that so many people are calling me foolish. Again.

I bought the tree for 6 dollars down in Lewiston at Garden Square Nursery. And maybe it was a foolish thing that I bought it because almonds don't belong in cold climates. Some people have managed to raise them at Lewiston, but I'm about 500 feet higher. I'm always trying to grow things that can't be grown (my nectarines are doing well though the fig tree died), so I bought and set out 2 little almond trees. They were practically alike—about 4 feet high with 8 twiggy branches. We pruned them both when we set them out, cutting off the tip of each branch. I winced when we did that. I hate to hurt anything, but the nurseryman said it would help them—that there wouldn't be so much tree for the roots to support while they were just getting started. They both grew nice green leaves and made a fine start for themselves this summer. Then I had to go away and spend months traveling and selling books. While I was gone fall came. Then winter.

I'm back. I've been back 6 weeks. And here in my yard is this foolish almond tree. Right outside my front door. I don't know whether to laugh over it or weep. Time and again I jump up and run to the window to look at it—can it be real? Yet it is; all my visitors have seen it too. Right this moment, in December, I am in my kitchen and my wood cookstove is burning with the hearty fire inside that we need to keep warm. Outside snowflakes float steadily down, piling up on the ground where the little almond trees stand rooted. And there is the one tree, looking just the way it ought to in a December snowstorm: its leaves long since shriveled, changed color, and fallen away, the narrow whip of its lean young trunk waiting patiently for spring to come and transform winter's boredom into another frenetic season of growth like all sensible farmers and plants alike must accomplish. And then there is that other, foolish, tree.

I just got up and looked out the window again. There is the foolish tree, there in the snow, in the snowstorm. Its branches aren't 6 inches long like those of the wise tree. They are over 2 feet, though there aren't quite so many of them. And there are 47 lovely, spring-like, green leaves on that foolish almond tree. I went out and counted them. I stood shivering without my coat in the storm and gently touched the smooth green perfection of each one. Snow and ice were clinging to some so I gave the little tree a gentle shake to try to free it of that chilling burden. Then I looked down and saw 3 of those perfect leaves lying on the snow. Had I done that by shaking it, even so gently? I hurt for them. I felt so guilty for what I'd done. Yet, even on the snow and separated from their tree, they didn't look in the least wounded, not in the least dead.

I've been watching that foolish tree ever since I got home from my months on the road selling books. I've been waiting for it to give up and cut off the flowing sap to those green leaves like all the other deciduous trees in the orchard have, but it doesn't do it. And I'm starting to cling to the image of those green leaves in my heart as a symbol of Hope.

Has God given me a mutation? Or a miracle? An accident? Or a promise? Or just a foolish almond tree? Is the tree going to make it through the winter? Are 47 leaves enough if 3 fall each snowstorm? So many times God has pruned me, and I've lost green leaves and whole branches, but I knew He was shaping me for better things. That little tree is mocking the annual death we all accept so calmly: out there being summer in winter. Is it some genetic freak, lacking the inner knowledge to accept a winter's hibernation? Will it die completely after having made such a magnificent struggle not to sleep at all?

I'm the foolish one. Because I get weary. Discouraged. Because I consider, just for a moment, that maybe it would be possible to agree with everyone else and say, "Yes, it's too hard—it can't be done" about all the things I dream of, that I work and struggle to make happen. It would be kind of a relief to agree with them. Or am I foolish? Because I believe that life can be full of wonderful joyous miracles . . . if we only stretch out our arms, our living branches, and let life flow through us unceasingly, no matter what the weather report.

God has set a foolish almond tree outside my front door. My beloved, wonderful, foolish almond tree isn't a figment of literary imagination. Nothing in this book is. Sometimes I have wild thoughts of running out and wrapping it in my big warm winter coat and in my arms till spring. Or I get up on a new morning and go to the window thinking: Now, finally, it will have accepted the inevitable and dropped those leaves. But no, there it stands. Green. I remember my pastor saying that he will die only at God's appointed hour for him to do so and no mere disease will change that fact. Oh, foolish tree. God's perfect thing. Reminding me that the Valley of the Shadow of Death is just that, only the valley of the shadow of death.

HOW TO PRESERVE A HUSBAND
Be careful in your selection; do not choose too young and take only such as have been reared in a good moral atmosphere. Some wives insist on keeping husbands in a pickle, while others put them in hot water. This only makes them sour, hard, and sometimes bitter. Even poor varieties may be made sweet and good by garnishing them with patience, well-sweetened with smiles and flavored with kisses to taste. Keep warm in a steady fire of domestic devotion and serve with peaches and cream. When thus preserved, they will keep for years.

PRESERVED CHILDREN Take 1 large field, a dozen children, 2–3 small dogs, a pinch of brook, and some pebbles. Mix together children and dogs; sprinkle the field with flowers; spread over all a sky of deep blue and bake in the sun. When brown, set away to cool in the bathtub.

Once upon a time, in the bad old days when the Communists and the Western countries were poised on the brink of mutual nuclear annihilation, many of us in the back-to-the-land movement were poised to repopulate the barren earth by managing to be the only survivors of that holocaust. I built a fallout shelter in the backyard. It was very carefully designed, for I'd studied the subject thoroughly—enough to understand that the shelter could solve only part of the problem. But I had children to worry about, and although I couldn't do anything about nuclear proliferation, I could, at least, build a concrete hole. And I managed to do it quite economically for the quality of concrete I used. Thank God it was never put to the test.

All we have to worry about now are local nuclear conflicts, and nuclear power plants blowing up one at a time, and forever-deadly nuclear wastes piling up and leaking away into the planet's circulatory systems.

Another critical issue back then for would-be survivors was how to be self-sufficient, foodwise, if normal supply systems broke down and the grocery stores were empty. Unlike building a fallout shelter, growing your own food and having a good back-up supply in storage is still a worthwhile endeavor. The one thing that does not change is the fact that there will be changes. You can be certain there will be more crises. Most prophets of doom are right... if you wait long enough. How long? Centuries? Millennia? Which crisis will be next? Which will be worst? My bet is on some sort of "environmental" disaster.

In 1991 the United States imported more than half its oil, which accounted for 65 percent of our trade deficit. I recently saw a news item about how Cuba couldn't get any oil and was suddenly having to harvest sugar cane by hand and with oxen. We had a few generations to make the switch away from animal power to petroleum power. It is likely the switch back would happen as it did in Cuba—suddenly, unexpectedly, in an atmosphere of crisis. If what I've heard is true about the oil supply being expected to run out in 50 years, or 100, or 150, there are some big adjustments—or reversals—ahead. Even though it seems inconceivable, we may have to remember how to do things the other way, the way we did them before "progress" happened. (In some ways I would consider that a huge blessing.) But it's more complicated than that. Modern nations almost literally sow oil to produce food. If there were no oil, there would be no artificial fertilizers, no herbicides, no pesticides, no gas for the $50,000 ($150,000?) tractors that help us grow our food supply. If there were no petroleum, there would be no crop—except for what the organic farmers could produce without mechanized equipment. Our modern food supply is also utterly dependent on the petroleum products used to create the electricity that runs milking machines and electric egg incubators.

Other things have changed too. In the old days, there were no seed catalogs; people saved their own seed from year to year. There was no artificial insemination; farmers knew where to find a bull for their cows, because otherwise there would be no milk and no calf for meat the next year. There were no electric egg incubators; poultry species brooded, hatched, and reared their own young. Preserving food didn't require electricity or metal. If people's labors were fruitful, they put away a long-term food supply as a matter of common sense. And their food was wholesome, hearty, and free of carcinogens.

Thus, until about 70 (or fewer) years ago, families harvested in the fall and stored enough food to get them and their livestock through until the next harvest. Milk, butter, and cheese from dairy animals, along with meat and the stored foods, were important winter foods. Old-timers stored food mainly by root cellaring, drying, salting—or feeding to livestock, which returned the food as milk, meat, or work. The old-timers never let anything go to waste. After canning came along, most country families canned many, many jars of fruit, vegetables, and meats every year. When freezers were invented, some preserving, especially of fruits and meats, was shifted to that system.
Your first year, you may have trouble figuring out how to get organically grown food in bulk. It's best if you make arrangements the previous fall, so the grower can make sure to plant enough for your needs.

Plan Ahead

If you haven't previously raised your own food, I would guess it will take more food to keep your family going than you now realize. In general, can or freeze only the amount your family will use up before the next harvest season. In your first year, you may have trouble figuring out how much. But by your second, you'll know what ran out fast and what was left over. With that info you can fine-tune your plan.

Do you know how many cows, goats, chickens, sheep, etc., you need for one year's supply of milk and meat? How much bushels (or acres) of grain? How many heads of cabbage and sacks of potatoes? You can find out to a certain extent by keeping records and then by experience. You'll need a lot of food, because people doing hard outdoor work have bigger appetites, because you have animals to feed too, and because you have to allow for loss by crop failure or spoilage in storage.

With pumpkins and fruit, you have to figure from harvest to harvest—a full 12 months. You store greens from fall to spring because you'll have them fresh the rest of the time, from dandelion greens in the spring to your last cutting of Swiss chard or mustard greens in the fall. Meat is a crop you can harvest in winter but not in summer—except for very small animals like poultry and goats. Milk is available fresh year-round—providing you have more than one animal milking and stagger the time they come fresh. You have to store enough winter feed for them. A hungry cow won't just grow lean. She'll either go way down on the milk, or she'll go through the fence and range onto the neighbors' land. (She is also likely to leave in search of a bull when she needs one—fences hold only contented cows.)

All spring I try to plant something every day—from late February, when the early peas and spinach and garlic can go in, on up to midsummer, when the main potato crop and the late beans and lettuce go in. Then I switch over and make it my rule to try to get something put away for the winter every single day. That lasts until the pumpkins and sunflowers and late squash and green tomatoes are in. Then comes the struggle to get the most out of the stored food—all winter long. It has to be checked regularly, and you'll need to add to that day's menu anything that's on the verge of spoiling, wilting, or otherwise soon becoming useless. Or preserve it a new way. If a squash gets a soft spot, I can gut it out and cook, mash, can, or freeze the rest for a supper vegetable or pie, or add it to the bread dough.

You have to ration. You have all the good food you can eat right at arm's reach and no money to pay... until you run out. You're likely to have either no elk at all or a lot of it (meatwise, an elk is about as much as a whole cow). Rotate

A Measure of Your Food Self-Sufficiency

See how your ability to feed yourself and your family measures up by the old-timers' standards. There are no right or wrong answers to this "test." Its purpose is just to help you evaluate where you are right now—and think about what direction you might want to expand in.

Do you grow your own vegetables? Yes No Percent
Do you grow your own dairy foods (milk, butter, cheese, yogurt, etc.)? Yes No Percent
Do you grow your own meat? Yes No Percent
Do you grow your own fruit, berries, honey, and sorghum syrup or maple sugar and use them for the sweets in your diet? Yes No Percent
Do you grow your own cereal and bread grains? Yes No Percent
Do you save your own seed from garden and grain patch? Yes No Percent
Do you have males for dairy and meat breeding or easy neighborly access to them? Yes No Percent
Do your orchard and nut and berry patches include young plants? Yes No Percent
Do you replace every tree you harvest? Yes No Percent
Is the land on which you grow food: Borrowed? Rented? Being bought on contract? Paid for? Yes No Percent
Do you preserve vegetables for year-round use? Yes No Percent
Do you make cheese from your extra milk? Yes No Percent
Do you preserve your family's food supply by salting? Yes No Percent
By drying? Yes No Percent
By freezing? Yes No Percent
By canning? Yes No Percent
By root cellar storage? Yes No Percent
Do you use cloches, a cold frame, or a greenhouse to prolong your growing season? Yes No
Do you have enough food on hand to feed the family 1 week? Yes No
2 weeks? 1 month? 3 months? 6 months? 9 months? 1 year? Longer? Yes No
Do you have enough seeds on hand to grow your food supply next year? Yes No
when you have a variety. If you have elk, beef, and some odds and ends of chicken, trout and ham, eat elk on one night, beef on the next night, and alternately chicken, trout, and ham on the night after that. Garden crops have a tendency to either fail completely or overwhelm you with abundance. Fruit comes by the barrel but for only a short time—even unless you can preserve it.

Plan ahead. Breed your milker 9 months before the time you'll want milk. If you butcher 30 chickens in June and have chicken every Sunday, you'll have no more after Christmas until next summer. And did you save layers? They may not lay in the winter, but hens that have rested will make up for it in May. Did you preserve eggs during that period when the hens lay like crazy—from May to October (or sooner)—just in case you don't see another egg until spring? I'll confess that I never manage to do all the food preserving correctly. But we keep struggling toward the ideal.

For information about planning a garden, see Chapter 2; planning an orchard, see Chapter 6; planning your meat supply, see Chapter 8; planning your dairy supply, see Chapter 10.

**Preserving Notebook:** Keeping one makes it possible to learn from experience. If you've the time and the patience, you can put down even more detail than this.

Record in the notebook:

1. When you butchered what and about how many pounds of meat you put into the deep freeze.
2. How many chickens you have and how many eggs you get.
3. How many goats you're milking and how much milk you get, and the same for cows or other dairy animals.
4. How many seed packets of what you planted, or how many pounds of potatoes. At harvest time write down how many bushels of spuds, etc. you had to go into storage.
5. How much you're spending every week on store-bought food and where you're spending it.
6. See if you can bring that down by using more home-grown ingredients.
7. How many mouths you're feeding and what age they are.
9. When you ran out.

A very organized reader named Lin Shoemaker, Pullman, WA, even records what recipes she used in her food preserving. She's looking for some worthwhile. Independence days are worth struggling for anything worthwhile, so it might as well be for the best food product is the one you grow or make yourself, starting with ingredients that are as natural as possible (or, if you're stuck in the city, the ones in your grocery store labeled "organic"). The results may not look or taste the best, but they really are the best. That's what I believe. When it comes to believing, you just have to believe whatever you believe and let it go at that without more fuss. Independence days are worth struggling for. They're good for me, good for the country, and good for growing children. I think being married to a fine man, raising children, and raising food are the most important worldly things there are. And the most rewarding.

I think the best food product is the one you grow or make yourself, starting with ingredients that are as natural as possible (or, if you're stuck in the city, the ones in your grocery store labeled "organic"). The results may not look or taste the best, but they really are the best. That's what I believe. When it comes to believing, you just have to believe whatever you believe and let it go at that without more fuss.

My ideal woman milks a cow or goats, gardens, and cares for her children herself. She hasn't got time for fancy cake decorating and vegetable dishes with 10 ingredients. And my ideal woman wants to use as few store-bought ingredients and gadgets as possible. She's looking for from-scratch recipes or making up her own.
USE WHAT YOU HAVE: There are a few basics to cooking in any food category. Some cooks use a recipe only to guide them through the first few times. Then they know the recipe by heart—or, better yet, know the principles involved and can strike off on their own to do variations on the theme. I don’t want to be a slave to recipes with ingredients that are unreasonable, inappropriate, and expensive—recipes that would have me running to the store way too often to search for strange ingredients. On the other hand, it’s interesting to learn about new foods, new seasonings, new cuisines. But ingredients are most exciting to me if I might be able to grow them.

The wonderful magic at the heart of a food-growing household is the magic that turns your home-produced turnips and cream, apples and meat into your meals. The moment of triumph is when you say to the family: “Here’s what we worked so hard to grow, and isn’t it good!” I think you cook most happily, freely, and independently when you make good things out of what the Lord is giving you!

Lane Morgan, author of the Winter Harvest Cookbook (Seattle: Sasquatch Books, 1990), says, “I agree entirely that cooks are spending too much time and money at the supermarket and the gourmet supply store. But I think we would profit by spending more time looking at cuisines of other cultures, to help us better use what our particular gardens can grow. Country people around here will eat canned green beans and carrots all winter, which are considerable work to put up, because that’s good American garden food. Meanwhile they could be eating fresh kale and leeks and Japanese mustards from that same garden, which would be tastier, more nutritious, and easier all around, but they don’t because that’s foreign stuff and they don’t know the Greek or Indian or Japanese techniques to make them wonderful. They’ll make clam dip from a package, but they won’t consider an Indian chutney made of garden mint and September peaches—because that’s the way they grew.

Making menus out of what you can grow is the way Great-Grandmother did it. Each week she looked in the larder and the cellar and took a walk through the garden to see what she had to work with. Then she made menus. When she had eggs and milk aplenty, a little honey, and some stale bread, the family had a bread pudding. In May she served rhubarb in it, in June strawberries over it, and in September peaches—because that’s the way they grew.

To have 365 days of independent eating, you’ve got to learn to eat what you can grow, and you’ve got to learn to grow what you want to eat. At first it will be hard, but stick to it. If you don’t like what you have, eat it anyway and use the energy of your distaste to figure how to get what you’ll like better. If your only meat is elk, eat elk until you can raise something else. If you miss bacon, get four little pigs. If you miss bacon, get four little pigs.

To have 365 days of independent eating, you’ve got to learn to eat what you can grow, and you’ve got to learn to grow what you want to eat. At first it will be hard, but stick to it. If you don’t like what you have, eat it anyway and use the energy of your distaste to figure how to get what you’ll like better. If your only meat is elk, eat elk until you can raise something else. If you miss bacon, get four little pigs. In six months they’ll be 200-pounders, and you’ll have a year’s supply of bacon plus a sow to breed and keep the bacon coming. If you’re still living in the city and you don’t have anything but dreams, try for fun buying only what you imagine you could grow—in a natural unprocessed state—like whole grains, and see if you can learn to live off it.

When lettuce is in season, have a salad every day—at least a few varieties of garden green beans and carrots all winter, which are considerable work to put up, because that’s good American garden food. Meanwhile they could be eating fresh kale and leeks and Japanese mustards from that same garden, which would be tastier, more nutritious, and easier all around, but they don’t because that’s foreign stuff and they don’t know the Greek or Indian or Japanese techniques to make them wonderful. They’ll make clam dip from a package, but they won’t consider an Indian chutney made of garden mint and September peaches—because that’s the way they grew.

If you don’t like what you have, eat it anyway and use the energy of your distaste to figure how to get what you’ll like better. If your only meat is elk, eat elk until you can raise something else. If you miss bacon, get four little pigs. In six months they’ll be 200-pounders, and you’ll have a year’s supply of bacon plus a sow to breed and keep the bacon coming. If you’re still living in the city and you don’t have anything but dreams, try for fun buying only what you imagine you could grow—in a natural unprocessed state—like whole grains, and see if you can learn to live off it.

When lettuce is in season, have a salad every day—you can’t preserve it. If you miss it in the off-season, contrive a way to raise winter lettuce in the house. If you miss sweets, learn beekeeping. If you have barley and corn, make your bread, pancakes, and pie crust out of barley flour, cornmeal crust, and a bear-meat filling. If you have some tough old hens past their laying prime, 3 extra male goats, and 100 rabbits, then learn good ways to cook tough old hens, goat meat, and rabbit.

SEASONAL EATING: At any particular time of year you’ll have a different set of fresh foods coming out of the garden and root cellar to complement what you have frozen and canned. Winter, cloche, cold frame, and greenhouse gardening enable you to have at least a few varieties of garden-fresh vegetables year-round. Even in chilly November, in a basic temperate-zone garden and with some attention to protection, you might be able to harvest broccoli, brussels sprouts, cauliflower, collards, cabbage, Chinese cabbage, carrots, escarole, kale, leeks, lettuce, parsnips, salsify, spinach, rutabagas, turnips, and winter radishes.

HOMESTEAD MENUS THROUGH THE YEAR: Here are some menus from back in ’72 and ’73. Those were my banner years for home growing and good cooking. It wasn’t “gourmet” or “health food” cooking. But we raised it ourselves without poisons and had plenty of food and plenty of variety. We dried fruit in our front yard. Mayonnaise was homemade. Butter was from our own churn and bread from our oven. Bacon or ham was home-cured, and sauerkraut was out of our crock, as were pickles. The root beer and ginger ale were homemade, too. We always had milk and usually an herb tea on the table.

Breakfasts. If your chickens aren’t laying, leave out the eggs.

1. Cornmeal mush; bread, butter, honey; soft-boiled eggs
2. Toasted sourdough bread; pork chops; applesauce; scrambled eggs
3. Homemade grape nuts with cream; sliced fresh peaches; poached eggs
4. Cornmeal mush; home-canned fruit; elk sausage (½ pork meat); fried eggs
5. Leftover boiled potatoes (sliced and fried); elk sausage; home-canned tomato juice; fried eggs
6. French toast (bread sliced and dipped in an egg-milk mixture and fried); honey and butter to go on the toast; fried pork side meat; wild plums
7. For a summer breakfast cooked outdoors: pancakes; goat’s butter, honey; stewed wild apples; fried pork side meat

Lunches

1. May lunch: scrambled eggs; leftover boiled potatoes fried with chopped green top-set onions; cooked, buttered asparagus spears
2. Fried leftover cornmeal mush with butter, molasses, or honey; blackberries; fried meat; bread and butter
3. Hamburger; sliced fried leftover boiled potatoes; tomato ketchup; bread, butter, jelly
4. Leftover stew, extended with some fresh vegetables; bread, butter, wild plum sauce; mint tea with honey
5. Ground leftover ham and pickles; cottage cheese (we eat it with milk and honey—except Mike, who prefers it with salt and pepper)
6. Sandwiches of herb bread and sliced cold venison roast; canned juice; pickles
7. A special lunch: cold leftover steak sliced in strips; fried potatoes and onions; hard-boiled eggs; canned apple-sauce; bread and butter; iced wild strawberry leaf tea

Spring and Summer Suppers
1. Potatoes; bread; creamed onions; stewed dandelion greens; fresh raw asparagus
2. Dandelion greens and (real) bacon bits; roast ham and gravy; potatoes; stewed rhubarb; radishes
3. Leaf lettuce salad; radish roses; potatoes; fried meat and milk gravy; strawberries on leftover bread with cream
4. Leftover sliced cold roast; bread and apple pudding (crumbled bread crust baked with milk, sliced cored apples, beaten egg, honey, cinnamon); warmed-up leftover gravy extended with milk (to go on the meat); boiled Swiss chard
5. Chicken stew (made from an old layer, with carrots, potatoes, onions, turnips) and dumplings; blackberry-apple bread pudding (berries, apples, milk, bread crust, and honey, baked and served with cream); iced herb tea
6. Corn on the cob; sliced fresh fruit; roast; mustard greens; potatoes; half-cured crock pickles
7. Carrot sticks; boiled peas; boiled new potatoes; fried chicken and gravy
8. When you're hot and tired: potato salad (made ahead and chilled); barbecued meat (cooked by husband); tossed green salad (made by children); raspberry ice cream; boiled potatoes with giblet gravy; boiled green beans and onion and bacon; boiled potatoes with giblet gravy; sweet crock pickles; bread and cheese; brandied peaches (buried in September and dug up for Thanksgiving); root beer

Leftovers like cold sliced roast or cold boiled potatoes are good with some salt or butter. My husband Mike doesn't like to eat leftovers, except potatoes and meat, so if somebody doesn't snack them up, the chickens or pigs get them—except for bread, which metamorphoses into bread pudding or lunch dishes that I serve when it's just me and the children.

Feasts. Holiday feasts are wonderful rituals that bring a family closer, a time to pull out all the stops and load the table with everything good you can think of.

Thanksgiving 1972. Gander (the one that bit our son Danny twice) stuffed with sage dressing; sliced tomatoes (last of the fresh ones—picked green just before frost and stored to ripen gradually); cooked pumpkin mashed with butter; boiled green beans with onion and bacon; boiled potatoes with giblet gravy; sweet crock pickles; bread and cheese; brandied peaches; canned apricots, dried fruit salad (grated carrot tossed with chopped dried fruit and mayo); bread and butter; pumpkin pie.

Christmas Dinner. Turkey and dressing; peach ketchup; potatoes and giblet gravy; boiled green beans; carrot and dried fruit salad (grated carrot tossed with chopped dried fruit and mayo); bread and butter; pumpkin pie.

A SYSTEM FOR MENU PLANNING: My mother taught me the following basics of menu planning. I've heard of other systems, but this is the one I grew up with. It has served me well enough that I'll pass it on. To me, if something works, then it was obviously made in Heaven. This worked for me and my mother and, for all I know, for Great-Grandmother, too. But it's sort of like Infinite Goodness; I'm always striving after it and often falling short. Still, if you're striving after a good thing, usually even your failure will be a sort of success.

Breakfast. My mother's rule was to include a fruit or fruit product, a meat, a starch, eggs, and a beverage. That was a huge country-style breakfast for men who were going to do hard physical labor all day. Modern, more sedentary and health-conscious folks are cutting back on cured meats and high-fat and high-sodium foods. So I now suggest you omit the meat or eggs—or both! Anyway . . .

A "fruit" can be a glass of fruit juice, sliced orange sections (cut orange on the equator; then get about four
CHOOSING FOODS TO REDUCE HEART DISEASE AND CANCER RISK

Heart disease is this nation's Number 1 killer. Cancer is next. Here are my 11 guidelines for healthy eating.

1. Eat a variety of foods.
2. Maintain a healthy weight.
4. Eat plenty of vegetables and fruits. Eat strawberries, tomatoes, or cauliflower daily; eat citrus fruits and juices, green peppers, and broccoli 3-5 times a week.
5. Eat brown rice, pasta, whole grain cereals, and legumes generously. Grain products and legumes provide lots of fiber, which protects you from some kinds of cancer.
6. Use sugars only in moderation.
7. Use salt and sodium only in moderation. Avoid salt- and pickle-cured foods.
8. Avoid cured and smoked foods.
9. Avoid seafood and fish that might have come from polluted waters.
10. Avoid alcohol. Or, if you drink alcoholic beverages, do so only in moderation.
11. Always eat organically grown foods whenever you have the choice.

A "green vegetable" can be peas, beans, Brussels sprouts, broccoli, cabbage, collards, spinach, lettuce or any of the many other leafy greens, green onions, green peppers, and so forth. A "yellow, red or white vegetable" can be carrots, turnips, squash, sweet potatoes, cauliflower, parsnips, pumpkin, corn, radishes, beets, tomato, eggplant, and the like.

"Something sour" can be anything of the pickle, relish, spiced fruit, or vinegar family. "Something sweet" to me usually means fruit or a pudding sweetened with honey.

The "beverage" in summer is homemade root beer or ginger ale, cold water, iced tea and milk for the small children. In winter it's tea or honey and lemon with hot water, a mulled beverage, eggnog, or milk lassie made with hot milk.

Food Preservation Methods

This section describes general methods of food preservation. For detailed canning, freezing, drying, or root cellar storage procedures, look in the chapter that covers that food—for grains, Chapter 3; for herbs, Chapter 5; for fruits, Chapter 6; meats, Chapter 8. For vegetables, look in Chapter 4; pickles are mostly discussed under "Cucumbers" and sauerkraut making under "Cabbage" in that chapter.

IN-GROUND STORAGE: Some people say you should leave most of the root vegetables in the garden during the winter, even after they're grown, rather than using other preserving methods. Parsnips and salsify are about the best for that; they're often left in the ground over winter with a mulch over them. But I tried that and despaired. Every time I wanted something out of the garden, the ground was either frozen so solid that I couldn't dig it up, or it was so wet and muddy that I could barely manage to pull my legs back out of the garden soil, much less bring an armload of vegetables with me. If the ground freezes down far enough to freeze your vegetables, they will get soft and be no good anyway (except for leeks). I guess it depends a lot on where you live or what your garden storage system is. For more information, see "Extended Season Gardening" in Chapter 2.

DETERIORATION IN STORAGE: We share this wonderful world with myriad invisible but ravenous little critters who love to eat exactly the same things we do. The food preservation game is to get a move ahead of them and "enzymes," which are chemicals contained in the food itself that can cause undesirable changes. Salt, sugar, alcohol, sodium benzoate, and sulfurous acid are "chemical" preservatives.
that, in effect, poison or make the food yucky to the beasties. Drying food makes it impossible for them to grow and reproduce in it. Freezing puts them into hibernation except for the most cold-hardy, which can then double their number only in months, perhaps, rather than in hours. Canning, when you do it right, kills every last beast in the food and seals it up tight so that no more can get in. Cellar storage takes advantage of certain living foods' natural defenses against spoilage.

All stored foods, no matter how they are stored, slowly but steadily lose quality and nutritional value as time goes by. Some foods deteriorate faster than others. If a food was on the verge of spoiling when you started, it may lose quality more quickly in storage. Some storage methods, such as canning and drying, hold the food better than others. The biggest single risk factor for most stored foods is warmth, which causes the loss of both nutrition and palatability. With few exceptions, the cooler it is (above freezing for nonfrozen foods), the better they keep. For every 20 degrees' increase in storage temperature, you lose one half of the possible shelf life of most stored foods. The ideal storage temperature is 38–40 F.

**THE BASIC METHODS:** There are 6 basic methods of food preservation: canning, freezing, drying, pickling (for salt, vinegar, and spices), sugaring (for jams and jellies), and root cellaring—underground or even in the garden (live storage). Root cellaring is the oldest method, but not all foods store well using that method; in fact, most don't. Freezing is the most popular method and the next easiest, but it's also the most expensive, and you have to own a freezer and have electricity. Canning takes the most time and effort, but the food can be safely kept (if you carefully follow the rules) and stay delicious.

**PRESERVING MEAT:** Our family of 7 (and very often extras) can use 2 big calves, 4 pigs, maybe half an elk, and 50 or more chickens a year. The pigs supply cooking grease as well, which can be canned or stored in the deep freeze. Without electricity to run a deep freeze, you can't keep meat frozen, except if you live where there is a really bad winter—and even then, only during that winter. In most places, your outside temperature will be below freezing sometimes, but you'll also get off-season thaws that could spoil the meat. So, without electricity, you'll have to either rent a locker in a nearby town, which doesn't cost much, or can most of your meat right after butchering. That's what the old-timers did, and they ate well. You can also dry the lean meat in small strips—jerky. But that isn't as tasty or chewable as canned meat. You can can the meat from any kind of animal; just bone it out first. Another food preservation system for meat is making
mincemeat at the beginning of the cool season. It will keep during the winter months in a cold, outdoor place.

**Cost Comparison:** Another way of comparing preserving systems is by their cost. From that point of view, in-the-ground in your garden is cheapest. Root-cellar storage is next, because you build the cellar and then have no additional expense. However, drying can be cheaper than root-cellar storage if you have to factor in the cost of a root cellar, for if you’re drying with simple sunshine, drying is free. If you’re using an oven or dehydrator, it isn’t.

Canning is a bit cheaper than freezing—even taking into account the cost of new jars, some sugar to add to your fruit, and the electricity it takes to heat your canner. If you live where electricity is expensive, the cost of canning can be as little as half the cost of freezing. On average, the electricity to keep 2 cubic feet of freezer space cold for 1 year in the Northwest will cost $7.68. On the other hand, electricity can the equivalent amount of food (assuming peaches here) on high heat for 1 1/2 hours would be only 13 cents.

But electric costs vary wildly depending on where you live. Here in the Northwest, we have just about the cheapest rates in the country. If you’re canning on a wood stove and have your own wood supply, then you don’t even pay for electricity, and once you have your basic jar collection, new lids are your only expense. Electricity to dry that amount of fruit would cost about 40 cents. Freezing is the most costly method because you have to buy a freezer and pay for electricity and wrapping material or containers to freeze the food in.

**Nutrition Loss in Storage:** But also consider, according to the USDA, that foods lose 60–80 percent of their nutritional value when they are canned, because of the high canning temperatures and water soaking. (Storing canned goods in a dark place minimizes the loss of riboflavin, which is caused by exposure to light.) Canned goods also lose vitamins from exposure to warmth. Frozen foods lose only vitamins E and B6, but if stored above 0°F, they can also lose a considerable amount of vitamin C and other nutrients, up to 40–60 percent of their food value. Blanching before dehydrating helps hold vitamins. Dehydrating using very low heat levels is less destructive to nutritional value than sun drying. However, dehydration results in more nutrition loss than any other form of food preservation. Live storage (in a root cellar) is the best for all holding nutritional value, so long as the food doesn’t freeze, the storage is cool, and the food is an appropriate one for this method. Heat, oxygen presence, and passage of time all cause losses.

Nutritionists are most concerned about what happens to vitamins A and C. Vitamin C is totally lost after sun drying foods (80–90 percent is lost after drying in a dehydrator) but is 100 percent retained in freezing. In canning, 25 percent of C is lost from fruits and 50–90 percent from vegetables. So they recommend that you dry or can high-vitamin A foods but freeze high-vitamin C foods.

**Summing Up Non-Food Factors:** Root cellar storage is cheapest of all and will retain most of the nutritional value. Of canning, freezing, and drying, freezing is quick and easy, but the most expensive; drying and canning are both cheap, but drying is by far the worst in terms of loss of nutritional value.

**The Food to Be Stored:** Yet another factor is that there are one or two best methods of keeping any single type of food. Sometimes even a particular variety of plant will keep better by one method than another. In my opinion, tomatoes, large fruits, syrups, fruit butters, and juices are all best kept canned. Cucumbers and cabbage are best pickled (preserved in salt). Green beans are good either canned or frozen. Corn, greens, peas, baby turnips, baby carrots, extra bread, meat, and hides waiting to be tanned are in my freezer. Berries are better frozen than canned. Fruits, except berries, are also very good dried. Apples are good made into sauce or butter and canned. Or you can dry apple rings or freeze slices in syrup for pie making. Onions, beets, green tomatoes, potatoes, winter squash, pumpkins, big turnips, big carrots, and celery will keep best in the root cellar. I didn’t include drying in this list, but if you live where there’s lots of dry, hot sunshine, this is also a wonderful option. Even if you don’t have to use an oven or dehydrator, it still may be a great option!

**Books, Containers, and Equipment**

**Food Preservation Books:** *Stacking Up III: The All-New Edition of America’s Classic Preserving Guide*, by Carol Hupping, covers canning, drying, freezing, root cellaring, plus preserving meat and dairy products. A similar, good, big, conservative, encyclopedic book on food preserving is *Putting Food By*, by Ruth Hertzberg, Beatrice Vaughan, and Janet Greene; it also covers making sausage, cheese, lard, and grits. *The Busy Person’s Guide to Preserving Food* by Janet Bachand Chadwick (1982) and *The Big Book of Preserving the Harvest* by Carol W Constenbader would also be helpful.

For commercial level postharvest technology, see the Wiley Encyclopedia of Food Science and Technology (4 vols., John Wiley & Sons, NY, 2000).

**Equipment:** If you are preserving foods gathered from your garden, orchard, and home butchering, you are periodically faced with preserving large amounts of the same thing—a mountain of apples, tomatoes, peaches, beans, etc. There are gadgets for sale that can make almost any food preserving process easier: cherry pitters, bean splitters, pear corers. And then there are the larger slicing, dicing, squeezing, and juicing types of machines. A “food mill” purées food and can also separate pulp and liquid; it’s good for making sauces, fruit butters, and leathers. An electric blender or food processor is great for making smooth-textured sauces and spreads, and for chopping finely. These are all wonderful if you can afford them, but are not absolutely necessary if you can’t. Everybody can afford some gadgets, though, even a humble one like a paring knife! A kitchen scale that weighs amounts up to 5 lb. is nice for making old-time recipes given in pounds. For heavier weights, use your bathroom scale.

C. F. Resources offers all kinds of food preservation stuff: vegetable strainers and juicers; canning funnels; a wide choice of pressure canners; American Harvest dehydrator; gamma seal lid to go on grain/bean storage buckets; opener for plastic pails; pasta makers; sprouting trays; grain grinders; 1-lb. dry yeast packages; and much more. Free catalog: 719-962-3228; www.cfamilyresources.com.
Over the years you’ll find ways to acquire such gadgets. They save you time and energy and make food preserving more fun. Make sure you have a special place to keep directions for use, parts ordering info, and warranties—an envelope in a special drawer, maybe, or a photo-type album kept with your cookbooks.

**PLACES TO BUY CONTAINERS**

Basco, 2995 Palmer Ave., University Park, IL 60466; 800-776-3786; [www.bascousa.com](http://www.bascousa.com); food and water storage containers and seals.

Container Store, Melvin Selcer, 314 S. Main, PO Box 263, Agra, OK 74824; 918-375-2601.

Drumco/WaterTanks.com, PO Box 340, Windsor, CA 95492; 901-396-6484; 877-655-1100; [sales@watertanks.com](mailto:sales@watertanks.com);

Major Surplus & Survival, 435 W Alondra Blvd., Gardena, CA 90248; 800-441-8855; offers gamma seal lids, etc.

NITRO-PAK Preparedness Center, 475 W. 900 S., Heber City, UT 84032; 800-866-4876.

The Wheat Bin, 620-345-2611, offers 5-gal. buckets, $3.65, or 6-gal. buckets, $4.

**USING SAVED CONTAINERS:** Back when I first wrote this book, public recycling was barely getting started. Back then thrifty housewives saved things like containers and found good uses for them at home. That principle can still apply.

NOTE: Polyvinyl plastic may cause cancer, so do not use plastic garbage cans, wastebaskets, or garbage bags that are not "food-safe" to hold food.

Cans. The 46-oz. juice cans are good lard holders. You can just fit a baggie over the top to make a fairly tight cover before putting it away in the freezer. Or put the right size "food-safe" baggie inside to line the can and fill it with liquid or food. Then tie, or wire shut, the baggie at the top and use it as a freezer container. One-gallon cans are good lard containers, too, and good grain holders to feed the chickens. Punch a few little holes in the bottom of your small cans, and you can start plants in them indoors. Cans make the best plant pots I know—except for peat pots, which aren’t reusable or as sturdy, and you have to buy them.

Glass. Any gallon jar (glass or plastic) is good for many things—holding milk, pickling, anything you need a "crock" for. Widemouthed jars can be used as drinking glasses, or to hold seeds, crayons, Scrabble letters, or other odd things. In the summer, the children need jars with holes punched in the lid for grasshoppers, spiders, and so on. Small jars can hold dried herbs and spices, dried jerky, dried fruits, and crackers.

Paper. I wouldn’t store (or eat off, or wipe with) white paper, because much white paper is bleached and has traces of carcinogenic dioxins in it. But brown paper bags are healthy to store in, as long as the food is dry and you don’t heat the bag.

NOTE: Don’t ever put a paper bag in a microwave or regular oven though, because bad chemicals will leach out of the paper when it gets hot.

Found Toys. There are 3 places in my kitchen where children are especially welcome. One is the box that holds their toys, coloring books, and so on. The second is the special drawer where I keep my collection of lids, which double as toys. They think of their own games to play with the lids, and the possibilities are practically infinite. Toddlers love the clunky bright metals, especially the doughnut-shaped canning screw-tops. Bigger children make up matching games. The woodbox is their other favorite kitchen toy box. All kinds of forts, houses, barns, highways, railroads, and towers go up on my kitchen floor. They all end up in the stove, of course, but then the children are very willing to haul in more wood for me.

**DRYING**

Sun drying is the oldest method of food preservation. Nowadays it is the least common form. Too bad, because drying is a cheap, easy way to preserve, and everybody loves the results. You can dry fruits, vegetables, meats, fish, herbs, berries, edible flowers, nuts, and eggs. For directions, look in the entry in this book that tells you how to grow them. Small, thin, leafy herbs are the easiest foods to dry. Apples, apricots, cherries, and coconuts are the easiest fruits. Easy vegetables are mature kidney, mango, pinto, red, black, and soybeans; green lentils; chili peppers; parsley; celery tops; mature sugar, cow, pigeon, and other peas; sweet corn; sweet potatoes; and onions. You can make jerked meats, vegetable chips (corn, potato, zucchini, etc.), and much more. Dried foods require less space and weigh less than foods preserved in any other manner.

**LOW MOISTURE:** Dried foods are preserved by their very low moisture content, so if in doubt, it’s better to get them too dry rather than leave them too moist. The moisture content of a well-dried food varies with the food, from as little as 5 percent for leafy vegetables up to 25 percent for acid fruits. Most microscopic beasties won’t grow in a low-moisture environment. The beasties aren’t dead, however—they’re just waiting. Research on drying and dehydrators is going forward at a marvelous speed, so your drying results can be better all the time. Recent problems with canning lids, shortages of jars, and threats to public power have really impressed on me the importance of knowing how and being equipped to dry. Friends who fed me their home-dried foods eliminated my last shred of prejudice against dried vegetables. They were delicious!

**DRYING INFO AND SUPPLIES:** Get the latest extension service bulletins on home drying, probably free or at least cheap. Horizon Publishers (801-295-9451) specializes in dehydration books. They offer *The ABCs of Home Food Dehydration* and *New Concepts in Dehydrated Food Cookery*—
Hundreds of New Ideas and Tested Recipes for Enjoying Home Dehydrated Foods, both by Barbara Densley; Fun with Fruit Preservation—Leather, Drying and Other Methods by Dora D. Flack; Home Food Dehydrating—Economical Dolt-Yourself Methods for Preserving, Storing, and Cooking by Jay and Shirley Bills; and Just Add Water—How to Use Dehydrated Foods and TVP by Barbara G. Salsbury. There's also Making and Using Dried Foods by Phyllis Hobson; Food Drying at Home by Bee Beyer (300+ recipes for dried foods); and How to Dry Foods by Deanna DeLong. ATTRA's booklet, "Options for Food Dehydriation," is at www.attra.ncat.org/attra-pub/dehydrate.html.

Dry It—you'll Like It by Gen MacManiman (75 pp., $10) is a fun drying book—the first of them, and still a good one! Gen, now 86 and still going strong, offers her book, her personal line of Living Foods Dehydrators (your choice of three sizes, plus kits for those three sizes, plus they sell parts to make your own), and a free basic catalog of drying supplies: Living Foods Dehydrators; 425-222-5587; 3023-365nd SE, Fall City, WA 98024; www.dryit.com. From Gen's catalog you can order heat-fused polypropylene tray screening that is nonstick, absolutely food-safe, and easy to clean. You can get dryer thermostats and an electric food dryer designed specially adapted to powder dried herbs and vegetables, which you can then use to make your own instant soups and teas. (Powdered dried vegetables and meats are also nutritious additions to pet food or baked goods.) She also sells guar gum, a natural, excellent thickener for fruit leathers. Her growbox attachment turns a food dryer into a little hothouse for germinating seeds or sprouts. She offers Teflon sheeting—a permanent, nonstick, wipe-clean base for drying fruit leathers.

"Freeze Drying": This isn't something you can do at home. Food is freeze-dried by being spread on trays and then frozen there. Then the tray is put into a vacuum chamber. All the air is pumped out and the chamber is heated. The heat melts the ice, which turns directly into water vapor in the vacuum and is then pumped out of the chamber. Freeze-drying gets food drier than other drying systems; moisture is below 2 percent. So freeze-dried food stores longer and more safely.

3. Pre-Drying Treatments for Fruits: Fruits do not get blanched, but some people believe that the larger, lighter ones are improved by dipping in ascorbic acid, salt water, fruit juice, or honey solution before drying. The dips are useful for apples, pears, apricots, peaches, and other light-colored fruits that turn brown (an oxidation reaction) if exposed to air. A mere change of color would be no big deal, but oxidation also damages flavor and destroys some of the vitamins A and C. Most dark-colored fruits, such as figs, prunes, and grapes, don't oxidize. For those that do, here are harmless ways (unlike sulfuring, which is harmful) to prevent or minimize oxidation. The ingredients for these solutions are available in various places; try your grocery store—or your drugstore.

Salt-Water Dip. To keep fruits from darkening, you can slice or chop them directly into a gallon of water that contains 6 T. flaked pickling salt. Soak no more than 5 minutes so it doesn't get mushy with water content or too salty-tasting.

Ascorbic Acid Dip. Ascorbic acid is a form of Vitamin C. To make it, crush 5 one-gram Vitamin C tablets, or add 1 or 2 T. ascorbic acid crystals or powder to 1 qt. lukewarm water. Slice or chop your fruit right into this solution. Remove the fruit from the dip before it gets soggy. Drain and dry.

Commercial Fruit Preservative. This is a powdered mixture of Lascorbate, sugar, and maybe also citric acid. Just follow directions on package.

Sulfuring (or Not). The "sulfur" used for this purpose isn't usually pure sulfur. It's one of several preservative compounds containing sulfur that prevent darkening of light-colored fruits and repel insects. I don't give a hoot or a howl what color things are—dark skins are just as good as light ones, and vice versa. And I think that what insects would consider inedible probably wouldn't be healthy for my kids either. And I hate using chemicals unnecessarily. And unsulfured food tastes much better to me and digests easier. And 5 percent of asthmatics are sensitive to sulfites (some non-asthmatics may be also). The USDA says, "Those persons who are sensitive to sulfur dioxide and sulfiting agents have experienced sudden attacks of asthma, difficult breathing, nausea, diarrhea, and even death" after eating sulfured food. NOTE: Sulfur fumes are injurious. If you sulfur, you must do so outside and avoid breathing the fumes! But I'm not going to tell...
you how to do it. Gerald Lehman, supplier of food dryers to the Amish, gets the last word here: “There is no need for chemicals or additives. Dried and properly stored dried foods will last as much as five years. Simply slice, dry, place in jar, and store in cool, dark area.”

4. PRE-DRYING TREATMENTS FOR VEGETABLES:
Blanching is a hot water “dip” or a period in steam. It is used for vegetables to be dried or frozen. Vegetables should be blanched to reduce the risk of spoilage of low-acid vegetables; to halt enzyme action, especially the enzyme that causes first ripening and then over-ripening; and to tenderize them. However, drying slows the enzyme action anyway. Those who research in this field say that most vegetables will retain more flavor, color—and possibly also nutrients—if they are blanched before drying. Not everybody blanches, but many do, especially if the veggies are old, have been gathered too long, or were grown under very dry conditions. Chili peppers, onions, celery, zucchini slices, thinly sliced mushrooms, and garlic need not be blanched.

The Non-Blanchers. Crystal Glenn (beautiful name!) of Aspen, CO, has lived on a farm most of her 52 years and makes soap, bread, butter, cottage cheese—and raises chickens and dried foods too. She wrote me that she has never steamed her fruit before drying it, nor has she blanched her vegetables. She said, “I’ve never had anything spoil or get wormy.” Catherine Humes wrote me that the only food she ever steams before drying is potatoes, “so they won’t turn black.” Farmers’ Bulletin 841, put out by the USDA in 1917, agrees: “Blanching of vegetables is considered desirable by some housekeepers, but it is not strictly essential to successful drying.”

Steam Blanching. You need a heavy pot or double boiler that has a tight-fitting lid, plus a wire basket that can be suspended over about 2 inches of hard-boiling water. The chopped or sliced vegetable in the wire basket shouldn’t be more than 2 or 2½ inches deep. That way the steam flow will stay strong enough for all the food to blanch properly. Put the vegetable in over the boiling water, and cover tightly so your steam doesn’t escape. If you don’t have a steamer, put a sieve in the pan (hanging over the boiling water) or suspend a bag with the food in it over the edge of the pan. The important thing is to keep the food out of the boiling water so you actually steam rather than boil it. Blanch for the suggested number of minutes. Or just estimate: leave veggies in there until the are heated clear through and wilted, or until they look translucent when cut, tender but not completely cooked.

Boiling-Water Blanching. Start out with the kettle, but use lots more water. Put the food in the wire basket, but in this case you dunk the basket right down until the vegetable is all covered by the boiling water. Start counting as soon as the water starts boiling again and leave it in there for the recommended amount of time. You can use the same water over and over. Use at least 1 gal. water per 1 lb. food. You need plenty of water so water will boil again soon after immersion and for best heat distribution into the food mass.

After Blanching. Pull out the vegetable, drain, chill by plunging into ice water or under cold running water, and drain again. Merely draining doesn’t get it dry enough to go into a dehydrator. Blot vegetable dry with cloth or paper towels.

5. SPREAD ON TRAY: Spread your vegetables or fruit on the drying trays, one layer only in thickness, except for leafy stuff like parsley or herbs, which can be loosely mounded a couple inches deep. Don’t dry very moist foods together with almost-dry ones. Dry strong-flavored (or -colored) foods by themselves. Set each piece separately (not touching) with air space between it and the next one. When drying look-alike herbs and fruit leathers, label them before drying.

6. SET TRAYS IN HEAT: Set them out in the sun, in your attic, or in your solar oven or electric drying situation. Dry at a low temperature for better flavor and color, safer storage, and no risk of burning. The drying temperature must be high enough that the food will dry before it spoils, but low enough that the food doesn’t cook or get hard on the outside while damp inside. Within those limits, the faster a food dries, the better its final quality.

7. STIR OR TURN FOOD: Turn the food often enough to keep it from sticking. Turn big-hunk kinds of food at least 2 or 3 times a day to speed drying and prevent sticking. Stir small pieces of food. Using a dehydrator, move most-nearly-dry foods to the bottom trays and put new and moist ones into the top. As foods shrink, you can consolidate to save tray space.

8. DONE WHEN? Fairly dry food may last a month or two. For longer storage, it needs to be completely dry. When is that?

Dry vegetables until they are brittle and will shatter when struck by a hammer, or until the dried slices crumble or break when bent. Fruits are dry enough when between leathery and brittle. Some fruits such as figs, cherries, raisins, and dates, are always sticky, no matter how dry. But even though still pliable, fruits must not produce any beads of moisture when squeezed.

Drying Methods

SUN DRYING: You can dry either by sunshine, in an oven, or in a dryer (“dehydrator”). I prefer sunshine drying over oven drying. Taste is good, there’s no expense or risk of burning or scorching. Sun drying is the basic commercial method too. Most apricots, raisins, figs, peaches, etc.—your grocery-store-dried fruits—were sun dried. Read Stella Andressy’s 1978 classic, The Solar Food Dryer Book, and Joseph Radabaugh’s exciting updates in Heaven’s Flame: A Guide to Solar Cookers (www.homepower.com).

Climate. For sun drying, your climate matters a lot. I live in a region where the days are very dry and very hot when fruit is in season. Hot days when the sun shines brightly all day long are perfect for sun drying. So outdoor drying is easy here in northern Idaho and in the dry Midwest and Southwest. It’s harder in the rainy, humid, coastal Northwest.

Nights. Bring trays indoors at night because cool nights put moisture back into the food. Drying in the daytime but re-moisturizing at night can result in moldy food.

Bugs. If the sunshine holds, insects are the biggest threat in open-air drying. If you are drying early in the season before the flies and wasps are about, you can simply put the food out on trays. Sun drying works best if the wasps aren’t around yet. Once August arrives, we are afflicted by wasps, with some child or other getting stung almost every day. I intensely dislike wasps, as does everyone else. Wasps especially eat meat and fruit. Fruit set out to dry not only attracts hordes of them, which is dangerous for the children,
but the wasps actually will eat it up themselves. Cherries and apricots usually come before the wasps, so I can just lay them out plain with at most a porous cloth over the top. They'll go ahead and dry underneath it. Once the bugs are about, you must dry under a cheesecloth or nylon net, using something to raise it so that there's no chance of it blowing onto the food, especially into a sticky leather. Or else put the food outside in a screened bug-proof setup.

Flies are the other possible problem. A fly now can mean a maggot later in some types of food, especially meats. That's the real advantage of drying inside the house in a sunny window spot, or up in your attic, which is probably warm, dry, and bug-free. Another good spot is in the rear window of your car with the windows rolled down only ½ inch.

You can make a screened-in sun dryer by starting with something wooden with four legs and a vaguely box-like structure, such as an unused rabbit hutch. I have a neighbor who did this. He replaced the top and bottom of the hutch with screen. He hinged the top and, just like that, he had a wonderful dryer in which to put the food trays. You can even design it so that more than one level of trays can be loaded in at once. Mike made me an outdoor dryer from an old wooden table: a screen on the top replacing the original tabletop and a screen on the bottom. The top was hinged to lift up, and the food trays went inside. But I have to confess that this nice dryer made from a table later evolved in the other direction and ended up becoming a rabbit hutch for Becca's two Christmas bunnies.

Secrets of Sun Drying

1. Don't dry outdoors where there is traffic pollution to avoid possible airborne lead contamination!
2. Don't ever lay food to dry directly on galvanized screen. The screen contains zinc and cadmium and will contaminate food.
3. Fruits can be dried nicely at 85°F or higher, but a temperature of 100°F or more is best for drying vegetables.
4. Always dry in full sun in a place where the air is moving as freely as possible.
5. Begin your drying with the trays covered with cheesecloth or some gauzy cloth (propped up to keep it from touching the fruit) in order to protect it from insects.
6. Fruits can get dry enough to store in a couple days. Vegetables may need as long as 3 or 4 days. It usually takes about 3 times as long to sun-dry as to dry in an oven or dehydrator.
7. Researchers have discovered that if you keep the drying process continuous by using an artificial drying system during the night, your food dries much faster and there is better quality, less loss of nutrients, and less risk of mold.
8. At the end of each day, turn your drying pieces and take your trays inside the house for the night to avoid dew. Set them out again the next sunny morning until the drying is done.
9. If insect eggs may have been laid on your food, "pasteurize" before storing (discussed later in this chapter).

Homemade Drying Trays and Outdoor Dryer. You can make portable drying trays by making square (more or less) frames of soft lumber. Across the top, staple or thumbtack a single thickness of curtain netting or some other strong but very porous cloth or Gen MacManiman's plastic screening—not metal, which may badly contaminate your food. The drying rack will resemble a window screen with a wooden frame. If you make your frame at least a couple inches smaller than the inside of your oven, you can also use these trays for oven drying. If the cloth sags, reinforce it underneath with string stretched from side to side. These screens are best when set up on posts or some such outside, so that air circulates through the mesh and all around your food. Inside the house, you can arrange a stack, with 3 or 4 inches between each tray, over the rear of your wood cookstove or heater, and dry food that way too. Allen Dong offers plans for a farm-scale food dehydrator at PO Box 413, Veneta, OR 97487. John Vivian published "How to Build a Food Dryer" in Mother Earth News, Feb./Mar. 1993.

Drying in an Oven or Dehydrator: Food dried in an oven or dehydrator generally has more color, flavor, and nutrients than sun-dried ones (except for leather). And there's no bug problem.

Any very hot, dry area such as your attic, your car's rear window, or around your heater or cookstove is a good drying environment. So is your oven, but oven drying, unlike sun drying, means you have to be on hand to keep an eye on what's going on. Using a dehydrator is more like sun drying in that it's usually foolproof; you can walk away and forget about it. Low-wattage dehydrators work well on electricity from alternative power sources and are still cheaper than canning. Dehydrators are the easiest to dry in. In your oven or dehydrator, you can dry year-round. Most, of course, during harvest, but . . .

More Dehydrator Uses. A dehydrator is good for more than dehydrating fruit! In a dehydrator, you can make fruit leathers, jerky, and crackers; dry vegetables and herbs; rejuvenate limp crackers or chips; dry bread sticks to use with dip; and dry homemade pasta. It's also good for raising bread and decrystallizing honey. Use it to dry flowers, dyed wool or wool sweaters, and lingerie. In some you can start seedlings, grow sprouts, and make yogurt.

You can dehydrate food leftovers (remove and discard all fat) to later toss into a stew, soup, or cassettele or munch for a snack: peas, sliced carrots, even leftover spaghetti cassettele! Dry the food you salvage from your root cellar storage, such as half a squash whose other half spoiled and went to the pigs, chickens, worm bed, or compost heap.

Temperature. The biggest problem with oven drying is that it is often hard to get a steady enough heat at a low enough temperature. The ideal drying temperature is 120–150°F. Over 150°F is potentially disastrous. Judging temperature can be a problem. Some ovens don't have a thermometer. If you don't have an oven thermometer, you can buy a portable one and put it in there; toward the rear of your top tray is best. If you can't get an oven thermometer,
you can judge temperature by feel. The food should feel cooler than the air in the oven. If it feels warmer to you, either you need less heat or the oven door should be opened wider.

Disengage, remove, or do not light the top heating element of the oven. Preheat it at its lowest setting.

Air Circulation. This is also a problem in the oven if you have a tight-fitting door. You want the air to circulate around the food to absorb the moisture and carry it away. So prop the oven door open at least 1/2 inch. Gas ovens need to be open at least 4 to 8 inches. It helps to put a fan at one side of the open door to drive the air through the oven. While drying, occasionally change the fan's placement from one side of the oven door to the other.

Food Placement. Don't overload trays, and don't arrange your trays solid wall to wall, or the air won't circulate properly. Use trays that are at least 1 1/2 inches smaller than the width and depth of the oven. Separate trays by about 2 1/2 inches. Allow at least a 3-inch clearance from the top and bottom of the oven. Don't load an oven with more than 6 lb. of food to dry at one time; the food nearest the heat will scorch and that farthest from it won't dry. Every couple hours or so, swap tray positions around in the oven. And stir small pieces of food on the tray so they are more evenly distributed. This also exposes any wetness to the heat. Turn over large chunks individually.

Done? Oven drying is much quicker than attic, on-a-cot, peach, or pear), heat puree to almost boiling (about 180°F) before drying. That will retard the browning. You'll Like It and in Gen MacManiman's catalog.

Ready-Made Dehydrators. Among the many brands of electric dryers available, the Excalibur is very popular. It is made of side venting. As the leather dries and gets more concentrated, it gets sweeter and a chemical change occurs that causes the creation of more sugar.

3. The fruit or vegetables need to have the consistency of a smooth puree that is thin enough to pour. Add more fruit juice (any fruit juice will be great) or water if thinning is needed. (Apple and pumpkin tend to need thinning.) But too much water makes a puree that's too thin; thin puree tend to make a leather that sticks to the drying surface. (Grape and berry purees tend to be too thin.) If the puree is too thin, thicken by combining with a thicker sort of fruit puree; by slowly cooking it down over low heat to evaporate some of that water before you start drying; or by adding a thickener. There are lots of possible thickeners out there: guar gum (1 t. guar gum per 1 c. juice; let rest 10 minutes before you proceed); psyllium seed husks (1 t. per 1 c. juice; let soak 5 minutes before proceeding); slippery elm (2 T. per 1 c. juice; let soak 5 minutes); wheat or oat bran; or chia or flax seeds.

4. If you're making leather from light fruits (apple, apricot, peach, or pear), heat puree to almost boiling (about 180°F) before drying. That will retard the browning.

5. Line a drying rack or cookie tray with food-safe plastic. Don't dry leather on wax paper or foil. The leather will hopelessly stick to them. Low-pectin fruits naturally stick more than high-pectin fruits. Combine with apple if you want to raise the pectin amount. If you're expecting a sticking problem, lightly coat the drying surface with a nonstick vegetable spray or vegetable oil. If your plastic is flimsy stuff and likely to blow into the leather, tape or clothespin the loose edges to each side of the pan. A 12 x 17-inch cookie sheet will be just right for about 2 cups of puree. For larger quantities, one system is to cover the top of an outdoor table with plastic wrap fastened at the sides and ends with tape. Pour your puree onto that. To ward off bugs, you can make a cheesecloth tent over it.

6. Pour your puree in and get it spread an equal depth by carefully tilting the tray one way and then another. The wonderful leather. In fact, slightly overripe fruit actually makes a sweeter, better-tasting leather! You just wash it, cut out the worst, mash, and dry. Bananas, even if almost brown, make fine fruit leather.

Steps to "Leather" Making

1. For any fruit, basically you just rinse it off and grind or force it through a sieve, mash with a potato masher, put through a food mill, or blend. Remove the peels, especially with pears, or you'll get a disagreeably grainy leather. Take pits and seeds out at whatever stage is appropriate. Too many seeds can really spoil a leather. You can store the mashed fruit in the freezer until you get around to making leather, and it will be all right. Even if it has started a wine-type fermentation, it will still make good fruit leather!

2. To make vegetables (squash, sweet potato, pumpkin, etc.) into leather, you have to precook and then sweeten and/or spice them to taste. You may like the final results of your fruit leathering better if you add 1 or 2 T. of sweetener per batch, and 1 t. lemon juice to light-colored fruits. You can vary sweetening and spices as you please, but you don't need to sweeten as much as you might think because as the leather dries and gets more concentrated, it gets sweeter and a chemical change occurs that causes the creation of more sugar.

3. The fruit or vegetables need to have the consistency of a smooth puree that is thin enough to pour. Add more fruit juice (any fruit juice will be great) or water if thinning is needed. (Apple and pumpkin tend to need thinning.) But too much water makes a puree that's too thin; thin puree tend to make a leather that sticks to the drying surface. (Grape and berry purees tend to be too thin.) If the puree is too thin, thicken by combining with a thicker sort of fruit puree; by slowly cooking it down over low heat to evaporate some of that water before you start drying; or by adding a thickener. There are lots of possible thickeners out there: guar gum (1 t. guar gum per 1 c. juice; let rest 10 minutes before you proceed); psyllium seed husks (1 t. per 1 c. juice; let soak 5 minutes before proceeding); slippery elm (2 T. per 1 c. juice; let soak 5 minutes); wheat or oat bran; or chia or flax seeds.

4. If you're making leather from light fruits (apple, apricot, peach, or pear), heat puree to almost boiling (about 180°F) before drying. That will retard the browning.

5. Line a drying rack or cookie tray with food-safe plastic. Don't dry leather on wax paper or foil. The leather will hopelessly stick to them. Low-pectin fruits naturally stick more than high-pectin fruits. Combine with apple if you want to raise the pectin amount. If you're expecting a sticking problem, lightly coat the drying surface with a nonstick vegetable spray or vegetable oil. If your plastic is flimsy stuff and likely to blow into the leather, tape or clothespin the loose edges to each side of the pan. A 12 x 17-inch cookie sheet will be just right for about 2 cups of puree. For larger quantities, one system is to cover the top of an outdoor table with plastic wrap fastened at the sides and ends with tape. Pour your puree onto that. To ward off bugs, you can make a cheesecloth tent over it.

6. Pour your puree in and get it spread an equal depth by carefully tilting the tray one way and then another. The wonderful leather. In fact, slightly overripe fruit actually makes a sweeter, better-tasting leather! You just wash it, cut out the worst, mash, and dry. Bananas, even if almost brown, make fine fruit leather.

Steps to "Leather" Making

1. For any fruit, basically you just rinse it off and grind or force it through a sieve, mash with a potato masher, put through a food mill, or blend. Remove the peels, especially with pears, or you'll get a disagreeably grainy leather. Take pits and seeds out at whatever stage is appropriate. Too many seeds can really spoil a leather. You can store the mashed fruit in the freezer until you get around to making leather, and it will be all right. Even if it has started a wine-type fermentation, it will still make good fruit leather!

2. To make vegetables (squash, sweet potato, pumpkin, etc.) into leather, you have to precook and then sweeten and/or spice them to taste. You may like the final results of your fruit leathering better if you add 1 or 2 T. of sweetener per batch, and 1 t. lemon juice to light-colored fruits. You can vary sweetening and spices as you please, but you don't need to sweeten as much as you might think because as the leather dries and gets more concentrated, it gets sweeter and a chemical change occurs that causes the creation of more sugar.

3. The fruit or vegetables need to have the consistency of a smooth puree that is thin enough to pour. Add more fruit juice (any fruit juice will be great) or water if thinning is needed. (Apple and pumpkin tend to need thinning.) But too much water makes a puree that's too thin; thin puree tend to make a leather that sticks to the drying surface. (Grape and berry purees tend to be too thin.) If the puree is too thin, thicken by combining with a thicker sort of fruit puree; by slowly cooking it down over low heat to evaporate some of that water before you start drying; or by adding a thickener. There are lots of possible thickeners out there: guar gum (1 t. guar gum per 1 c. juice; let rest 10 minutes before you proceed); psyllium seed husks (1 t. per 1 c. juice; let soak 5 minutes before proceeding); slippery elm (2 T. per 1 c. juice; let soak 5 minutes); wheat or oat bran; or chia or flax seeds.

4. If you're making leather from light fruits (apple, apricot, peach, or pear), heat puree to almost boiling (about 180°F) before drying. That will retard the browning.

5. Line a drying rack or cookie tray with food-safe plastic. Don't dry leather on wax paper or foil. The leather will hopelessly stick to them. Low-pectin fruits naturally stick more than high-pectin fruits. Combine with apple if you want to raise the pectin amount. If you're expecting a sticking problem, lightly coat the drying surface with a nonstick vegetable spray or vegetable oil. If your plastic is flimsy stuff and likely to blow into the leather, tape or clothespin the loose edges to each side of the pan. A 12 x 17-inch cookie sheet will be just right for about 2 cups of puree. For larger quantities, one system is to cover the top of an outdoor table with plastic wrap fastened at the sides and ends with tape. Pour your puree onto that. To ward off bugs, you can make a cheesecloth tent over it.

6. Pour your puree in and get it spread an equal depth by carefully tilting the tray one way and then another. The wonderful leather. In fact, slightly overripe fruit actually makes a sweeter, better-tasting leather! You just wash it, cut out the worst, mash, and dry. Bananas, even if almost brown, make fine fruit leather.
thinner your layer is, the quicker and easier it will dry. I recommend ⅛ to ⅓ inch. Get it too thick and you’ll have trouble with spoiling, or you’ll just plain get tired of having it around before it finally dries. If you get it thicker in the center than at the edges, you’ll end up with leather that’s brittle around the edges while still sticky in the middle.

7. You can dry by sun, oven, or dehydrator. Even home economists say that sun drying makes the best fruit leathers! They taste better and keep longer. When oven drying, try not to get the heat above 130°F and definitely not over 140°F! Oven drying with insufficient air circulation or excessively high heat tends to make a brittle leather. High heat also runs the risk of scorching the fruit or even melting the plastic! It takes longer to oven-dry fruit leather than plain fruit, but your leather could be done within 6 hours. In a dehydrator, dry at 120°F. Rotate pan or shelves often. When top side is dry, pull fruit off its backing. Dry with the down side up for about an equal time, and then you’re done. Drying time in the sunshine depends on how hot and how humid it is. As few as 8 hours is possible.

8. Fruit leathers that are still slightly sticky to the touch but peel readily from the plastic are dried enough if they’ll be eaten within a month or so, or frozen. They’re nicer for finger food, but will store only up to 3 months or so at room temperature; if dried until no longer sticky, they’ll store indefinitely (a year or more). Leather that is completely dried is mold-proof but tends to crack, crumble, and not roll. Pear, pineapple, and rhubarb leathers just naturally get more brittle during drying and storage than other kinds.

9. When your fruit leather is dry, cut it in strips about 1¼ x 2 inches, or into squares. If you made strips, roll each one up, tightly layered between waxed paper or plastic wrap. Wrap with plastic or paper on the outside. Or store in flat sheets with something between them. Enclose in a tightly covered moisture- and bug-proof container. Or you can just bag them up in plastic and store in the freezer. If the leather is not adequately protected from light, air, warmth, and moisture during storage, it will tend to darken and deteriorate.

10. To serve, you can cook up the leather like dried fruit, but children enjoy snacking on hand-held chunks so much that's generally the way mine goes. Children love them as much as candy. Other options are to dissolve the leather in water and use as a pie filling, serve as a dessert topping over a pudding or ice cream, or stir in yogurt to flavor it.

APPLESAUCE LEATHER COMBOS Mix applesauce with berries, or any strong-flavored or scarce fruit, to stretch it. Then use this mixture to make the leather, following the leather-making instructions above.

CRISP FRUIT WAFERS Add ½ c. wheat bran per 1 c. thin fruit puree. Mix well, and proceed immediately as if to make a fruit leather. What you’ll get is a delicious snack wafer. You can use oat bran the same way (especially good with tropical fruit juices), only it needs to soak for several hours before drying.

FRUIT LEATHER “CANDY” Sprinkle a breadboard with powdered sugar and work the leather strips on it, patting and rolling until about ¼ inch thick and powdered.

LEATHER-JUICE COMBO The essence of this method is that you steam or precook your pitted fruit, then pour the panful into a sieve. What stays in the sieve gets made into fruit leather by the above recipes. What runs through (without a struggle) gets made into juice. The more juice you get, the quicker what’s left will dry. This is really a great way to make your fruit juice without struggle and without waste!

FRUIT PASTE CANDY The pulp of two or more kinds of fruit can be combined for this. You can start from scratch with fresh, or use canned fruit! Just pour the pulp through a fine strainer. Then measure it. For each pint of pulp, add 1½ c. sugar. Cook, stirring constantly, until thick and clear. Then turn out on an oiled platter. Let dry until a good tough film is formed on the top. Then turn it out onto a plastic screen to finish drying. Dry until it loses its stickiness. The sooner you can get it dried, the better. I recommend open air and sunshine for the job.

SUNSHINE PRESERVES This is actually a partially dried leather. This is the way to proceed if you want to keep the shape of the individual fruit sections in the preserves rather than work with a pulp. Dry fruit only until it has a “jam” consistency; then stop. Try this with apricot halves, nectarine or peach slices, or whole berries. The fruits keep their shape and color well. Use 3 c. sugar and 2 T. lemon juice to 4 c. fruit. Combine fruit, lemon juice, and sugar in a pan. Stir gently to blend the ingredients. Now cover and let set at room temperature 1 hour. This is to extract some juice to cook it in. Now put it on the heat and stir until it boils. Then let it boil hard 4 minutes without stirring. Now cool, uncovered. Pour your preserves out into glass or plastic pans or trays, ½–⅓ inch deep. Set out in direct sunlight. If bugs or dust are a problem, cover with a pane of glass or clear plastic, leaving a 1-inch opening along the side. Once every hour stir a little bit. They are done when the fruit is plump (turn as needed) and the juice is about as thick as corn syrup. Your preserves will get thicker when cold.

UNCOOKED SUGAR-DRIED FRUITS To make this half-dried crock preserve, pit, peel, and cut up peaches, apples, sliced pineapple, or whatever. Dry partly. Then pack in a crock with sugar spread thickly between each layer. Another way is to halve peaches, remove the pits, sprinkle the cavities with granulated sugar, and dry in an oven. Currants and cherries can be boiled with ½ lb. sugar per 1 lb. fruit for 15 minutes and then spread out to dry.

Storing Dried Food

CONDITIONING: The Number 1 problem in storing dried foods is mold. The risk is highest in a damp climate. So conditioning is very important, because it equalizes
moisture so there are no damp spots where mold can get going. Conditioning allows excess moisture from some pieces to be distributed among and absorbed by drier ones.

After you finish the drying, put the food into a wide-rimmed, open-topped bowl for about a week. Give it a stir 2–3 times a day. Keep it covered with a screen or porous cloth fastened around the rim with a rubber band or string to keep out bugs. Then, if you wish, you can repack more tightly.

**The Pasteurization Option:** Some dryers heat up their dried foods once after they're done drying (and before storing) to "pasteurize" them. Other home dryers consider this step unnecessary and never do it. It's basically a final line of defense against bug problems. To pasteurize, heat the dried food before storing in a 175°F oven for 15 minutes, or in a 160°F oven for 30 minutes. Or else put in your line of defense against bug problems. To pasteurize, heat storing) to "pasteurize" them. Other home dryers consider dusting material. Gen McManiman suggests dusting ba­

**More Tips on Storing Dried Food**
1. Store in small batches because even one small still-moist piece can cause the whole container's contents to mold, and because dried foods are best if used within a short time after their container is opened.
2. If you live in a moist climate, put the dried food inside the jar, and screw the lid on tightly as soon as you've finished drying, so it can't accumulate moisture again.
3. The lid does not have to be a perfect-sealing canning-style lid; save your money. On the other hand, it's nice if the container is moisture-, bug-, and dust-proof. But the reality is that you can use almost anything for a while—and we do: even a paper bag, a recycled mayon­naisse jar and lid, or a plastic box with a tight-fitting lid.
4. Don't store in glass jars or clear plastic bags. It's nice to easily check and see just what's going on in there, but where there's light, there's oxidation; and when there's oxidation, there's nutrient destruction. If you do use a glass jar, line it first with a brown paper bag. If you must use glass and clear plastic, be sure to store it in the dark. Or you can store in paper bags.
5. In a humid climate, if your plastic or paper bags aren't airtight, you could put them inside a larger glass or metal container and put a tight lid on that. The outer glass or metal will also protect against insects or ro­dents. **Dried food should never be stored in direct contact with metal!** (Line containers with plastic or paper.)
6. Label jars and packages with the name of the food and date you dried it. An easy system is to just put a strip of masking tape on the container and write on that. Freezing and thawing doesn't hurt dried food.
7. Store out of direct light and in a dry, cool room. You can keep it dark enough by storing the jars inside a cardboard box or under a sheet of black plastic.
8. Check once or twice a week for the first several weeks, and occasionally after that. If you see moisture beads inside the jar, the food should be dried some more! Mold is the result of food that's too moist when stored or that is packaged so openly in such a humid environment that moisture is absorbed.
9. Dried food should stay in prime condition for at least 6 months and may last up to 5 years, but there will be slow but steady deterioration in the meantime.
10. If bugs get into your dried food, you can salvage it by removing them and then roasting the dried food at 300°F for 30 minutes. Repackage and store the food again in containers that don't allow air circulation or insect passage. It should be all right, but check again after a few weeks. If there are signs of bugs, give the food yet another heat treatment. Bugs are not poisonous, just visually unappealing.

### Using Dried Food

You can eat dried foods straight or "rehydrate" ("refresh") them by soaking or cooking in water, broth, or fruit juice. The warmer the water, the quicker the food will soak it up. Don't add sugar or salt to the rehydrating fluid; they both hold back water absorption.

Eat dried fruits out of hand for snacks at home, on the trail, or in lunch boxes. Or use pieces of dried fruit in cooker­ies, cakes, puddings, breads, etc. Reconstituted dried fruit makes nice stewed fruit or sauce served plain. Or add it to bread, gelatin, stuffing, homemade ice cream, milkshakes, or cooked cereal. Soak before cooking—6 hours or more.

Unlike fresh fruit, dried fruit needs little or no sugar. That's because the drying process changes the starch in the fruit to sugar. The dryness and the sugar content were the forces that combined to preserve it. A little lemon juice, though, usually improves the flavor.

Add dried vegetables to stews, soups, or sauces. Or make a basic soup mix by powdering them in a blender. Add herbs or spices and package for quick soup. Combine with dried milk for an instant cream soup mix. Use in meat pies and other main dishes or add to gelatin or vegetable salads.

**Basic Stewed Dried Fruit**

Pour 1 c. boiling water over 1 c. dried fruit. Add ¼ t. cinnamon, ¼ t. nutmeg, and a pinch of ginger. Let set until it softens to your taste. Tastes good sweetened with honey or mixed with yogurt.

**Fruit Granola**

Chop dried fruit into small chunks; half raisins and half other fruit such as apples, apricots, or peaches is good. For every 2 c. chopped dried fruit, add 7 c.
rolled grain (all one kind or a combo such as half oats and half wheat). Optional: peanuts, sunflower seeds, or other nuts and seeds. Stir together until well mixed.

**DRIED FRUIT AND RICE** Pre-soak 1 1/2 c. brown rice. Then cook. Add lots of dried fruits, pumpkin pie-type spices to taste, perhaps nuts, and a pinch of salt. Serve with your choice of milk, butter, or honey. This is great warmed up with hot milk for a quick, good breakfast.

**DRIED FRUIT JAM** Use dried fruit in any combination that suits you. Add extra sweetener if you like; 1/2 c. dried apricots with 1/4 c. dates, for example, is good. Make this in a blender and moisten with a fruit juice to enhance spreadability. One cup pineapple juice is about right in that apricot-date combo. It helps to soak the dried fruit overnight in the juice before blending. This dried fruit jam makes a nice syrup on pancakes and waffles too.

**DRIED VEGETABLE SLICES AND DIP** Slices of dried carrot, cucumber, eggplant, and tomato are good with a dip.

**INSTANT SPAGHETTI SAUCE** To a basic tomato puree, add dried onion, dried green pepper, dried basil, and oregano.

**VEGETABLE POWDER** You can grind any thoroughly dried vegetables in a blender or in Gen’s special powdering machine. Store in tightly sealed, small packages. To use, just add to boiling water. You can create your own formulas for instant soups or extra nutrition and flavoring for casseroles or stews.

**FREEZING**

Freezing is the most popular food preserving method. There is no risk of botulism. It’s simpler and far faster than canning. And it retains more nutrients than any other form of food preservation. Freezing is a wonderful system for preserving meat.

The foods that freeze least well are the ones that you are accustomed to eating crisp: celery, lettuce, cucumbers, green onions, green peppers, and radishes. But even these can be frozen and used in cooked dishes. Food varieties have become very specialized; the fruits and vegetables that freeze best of all may now be distinct varieties developed especially for that quality. Check with gardening neighbors or your county extension agent.

After the home freezer was invented, people soon froze more than they canned, and they still do. However, you need a real freezer. You can’t do serious food storage by freezing in that small space above the refrigerator. It isn’t big enough, it isn’t cold enough, and its temperature fluctuates too much for safe long-term storage. Upright or chest-type freezers will keep food in a good state for months or longer, though it will lose quality.

To sum up, freezing is great and most foods do wonderfully well in the freezer, even over long periods. But there is a big difference between food that has been in the freezer two weeks and food that has been in there a year.

**BOOKS:** See *The Complete Book of Home Preserving and The Home Freezer and The Complete Book of Freezer Cookery*, both by Ann Seranne. The new *Ball Blue Book Guide to Home Canning, Freezing & Dehydration* is available from Alltrista, Direct Marketing, PO Box 2005, Muncie, IN 47305. But there’s no substitute for experience. There’s no way you can kill yourself eating frozen foods. So don’t worry. Plunge in, start doing it—and you’ll learn how as you go.

**LOCKERS:** A “locker” is a box-like space that you can rent in a public walk-in freezer. They are wonderfully cold. You can rent all the space you need. They’re so cold that they’re good for quick freezing both meat from hunting or butchering and a mountain of vegetable harvest that you will sooner or later move to your home freezer. They’re good for holding a harvest overflow, and they’re priceless if your power or freezer conks out and won’t be operational again for a while. To find one, look in the Yellow Pages under “Lockers,” “Frozen Food Locker Plants,” or “Cold Storage.” Lockers are inexpensive to rent. Get the size you need. You furnish your own pad-lock, and you can come and go as you please to add or remove food.

**Once-a-Month Cooking:** As the owner of a freezer, you have the option of this exciting new concept in food preparation! Once a month, in 1 or 2 hard-working days, cooks prepare 30 or more meals at a time, then package them in portions and freeze. The rest of the month, they just pull them out of the freezer, thaw, and serve. (Thaw in fridge 24-48 hours. Then bake, if not pre-cooked—most of these are casseroles. Or microwave.) Once-a-month cooks say it helps them get the food budget under control, saves having to figure out what to fix for dinner every night, avoids excess visits to the grocery store, enables them to supply a meal on short notice with very little effort, and saves washing pots and pans every night. When a friend is sick, you can take her a meal from your freezer. And this system frees up a lot of time for things other than cooking.

Actually, not everybody who cooks this way makes 30 dinners at a time. Some cooks prefer to do it every 2 weeks and make 15 at a time, or to just double or triple the recipe every time they cook and put the surplus in the freezer. Some prefer to do 45 at a time! Learn once-a-month cooking with [www.simplemom.com](http://www.simplemom.com), the website of Deborah Taylor-Hough, author of *Frozen Assets Lite and Easy*. Or read *Once a Month Cooking* (also published as *Dinner’s Ready*) by Mimi Wilson and Mary Beth Lagerborg.

**Buying and Installing a Freezer**

**Conventional or Radical Alternative?** There are some amazing new appliances out there in the rapidly developing area of alternative energy products. Consider checking out the sources listed in Chapter 1 that specialize in these, and see what they’ve got. When you buy these pioneering products, you finance people who are doing urgently needed research and help test their innovations. Even more energy-efficient versions of standard mass-market freezers are a good investment. They’re likely to cost maybe
Frost or Frost-Free?

Frost-free freezers use more energy and tend to dry out food. With the other kind, you'll have to defrost once a year.

Chest or Upright?

The upright freezer takes up less floor space, is easier to see into and find stuff in, and you're less likely to lose stuff into the bottom until it is so old it no longer tastes good. In all other categories, the chest type is superior (and it is the most popular). The chest type is cheaper, won't need defrosting as often, and gives you more room for your money because you can pack it practically solid without everything falling out every time you open the door. It's also more heat efficient and better at keeping the food at the needed steady cold temperature because the cold air doesn't fall out every time you open the door. We have the biggest chest type there is. It cost about $250 [1974]. The freezer is a low-maintenance appliance. The guarantee probably won't be an issue for years.

Size?

Chest freezers range in capacity from about 5 to as much as 28 cubic feet. Uprights can be as small as small or even larger. On average, 1 cubic foot of freezer space will hold 35 pounds of frozen food. The size most often bought by families is the 16-cubic-foot capacity. The largest size freezers, 18 to 25 cubic feet, work well for large families that are doing major gardening, home butchering, and/or advance meal preparation. A family that uses its freezer a lot can make use of just about all the space they can get, as much as 7 cubic feet per family member. A bigger freezer can inspire you to do more food preserving, more baking and cooking ahead, and more shopping for bargains.

Some big families I know use 2 chest freezers. But I think one can do it for most families if you stagger the input. Vegetables and berries are frozen in season. Canning your fruit saves room. Wait to butcher until the weather is quite cold and there is increasing room in the freezer because the vegetables are being eaten up. On the other hand, if you have, say, two 10-cubic-foot freezers instead of one 20-cubic-foot one, you can use one for long-term storage and the other for frequently used items. The long-term foods will store better because the lid isn't going up and down all the time. And when you defrost, you can keep frozen goods in one while you defrost the other, and then switch and do the same thing to clean the other.

Cord and Plug: When you are setting up your freezer, put the cord and plug in a place that's as protected as possible from little gremlins. All they have to do is pull that plug to bring on a terrible disaster in the freezer. Since the first edition of this book came out, several people have written to tell me that you can buy a special attachment for a plug that makes it waterproof. Sounds like a great thing.

Where to Put It?

It would be nice to have it close to your kitchen, but freezers generally aren't in the kitchen. That's because the cooler the location you put it, the less the freezer will have to run, which saves on electricity. On the other hand, don't ever put a freezer where the temperature goes below freezing. Oddly enough, they're built to cope with heat (up to about 110°F) but not to endure that much cold. So consider putting it on a back porch or in a basement, attached garage, or any relatively cool part of the house. Set it out of direct sunlight and in a well-ventilated space. A 50–65°F room is good. Don't put it near your wood stove or furnace, or in a humid area; that hastens frost accumulation.

NOTE: Figure out where your freezer will go before you buy! Check to make sure doors and turns are wide enough to get it in there. Allow for a 4-inch space between the back of the freezer and the wall (to vent condenser-coil heat).

Ideal Freezer Temp:

The ideal temperature at which to set your freezer is -5°F. You can double-check the freezer temperature with a mercury-type thermometer. Food will keep longer at lower temperatures, but your electric bill will be proportionately higher, 0°F will keep it long enough.

NOTE: Don't set it any higher than 0°F Above that, food deteriorates much more quickly, even though it is still frozen.

Yes, I know that 32°F is the temperature below which things freeze, but though food stored even at 15–20°F seems solidly frozen, it just won't keep as well as food stored at 0°F or below. Even at a few degrees above zero, the freezer life of your food is cut in half! Those low-temp-specialist microbes are really something. If your freezer or freezer compartment can't keep food at 10°F or below, try to use it up within 2 months.

Also consider that the top center of a chest-type freezer tends to be a few degrees warmer than the bottom. In an upright freezer, the storage area inside the door tends to be the warmest. Adjusting the freezer compartment of your refrigerator to store food at 0°F will tend to keep the refrigerator section underneath below 37°F (the ideal temperature for preserving nonfrozen foods).

So if you want to save on the electric bill, a better way than turning up the temperature is to keep the freezer at least 70–80 percent full. Keeping air cold requires more electricity than keeping food cold! Keep the freezer door shut except when you absolutely have to get in there, and make it fast when you do open it. That helps keep it cold.

Be especially careful when the air is hot and humid. If your freezer is old, make sure it's staying well-sealed around the door. Gaps allow cold air to leak out and warm, moisture-carrying air to get in.

Milk Carton Tip: From Jan Grant, county extension agent, Seattle, WA: Fill up your extra freezer space with empty cardboard milk cartons full of water. Once they are frozen, they will help keep your food cold longer in case the electricity goes off. And you can use the block of ice when blanching vegetables for freezing: Put it in your chilling water. It's also an emergency water supply; just melt and drink.

Steps to Freezing Food

The four most important factors for success in freezing food are food quality to start with, speed in processing, airtight packaging, and temperature control.

1. Food Quality: Start with only high-quality, truly fresh-from-harvest food. You'll have best results if you choose young, tender vegetables. When I thin the carrots, I wait until I have some "baby" size—finger size, you can say. I pull those out and freeze them. That way I don't have to throw away any plants. I come back and get more later if the garden needs more thinning or my freezer needs them. Big carrots don't freeze well. They are better kept in the ground or in the root cellar, or sliced thin and dried. But those baby carrots can be frozen whole. The same goes for the baby beets. Beans for freezing should be no more than half grown, in the long, slender stage before they have...
gotten fat and tough with the beans inside too well developed. Full-grown vegetables are better off canned or stored in the root cellar. Lettuce, onions, cucumbers, and radishes don't freeze well.

2. **Process Quickly:** Get food, especially vegetables, from the garden to the kitchen counter as rapidly as possible. If vegetables are sitting, they're losing both nutrition and flavor. If they must wait, store them in a cold place.

3. **Prepare Food:** Wash the food thoroughly in cold water in a colander or sink filled with cold water. Scrub as needed with a medium-stiff bristled brush or a plastic or nylon-net scrubber. Lift the food out of the water when you're done to leave behind the grit that has settled to the bottom of the sink. If you want to freeze slices of vegetables such as broccoli, cut them before blanching, except for corn—cut it off the cob afterwards.

4. **Pre-Treat (Blanch) Vegetables:** Blanching destroys enzymes that cause food spoilage. Don't blanch chopped onions, green peppers, sliced mushrooms, sliced zucchini, or fresh herbs. It also isn't necessary to blanch vegetables that are to be stored less than 3 months. For longer storage it's not a matter of life or death, but color and texture will turn out better if you blanch. At first there's no difference, but after 4 or 5 months, blanched foods are much nicer.

**Non-Blanchers.** Not everyone blanches before freezing. Ione Thompson of Colusa, CA, wrote me, "We do not care to blanch many of the vegetables we freeze, as they lose flavor and crispness. With peas and beans (also all fish) we clean them, put into plastic cartons, and cover with water. When frozen, take from carton, put in baggie, and return to freezer. We wrap corn and asparagus tightly in foil, then put in baggies or freezer paper and freeze." Indeed, many vegetables can be frozen without blanching, but their storage life won't be as long. Other than those named above, the best vegetables not to blanch are celery, corn in husks, cabbage, sugar snap peas, summer squash, and broccoli. To see what you prefer, run an experiment. Blanch some of your vegetable and don't blanch some. Label the packages and compare the results.

**Equipment.** You need a deep kettle that contains boiling water; a colander and/or big sieve (to hold vegetables to be blanched) that can be immersed in the kettle without having the rim or handles go under water; and 2 buckets or double sinks full of ice and water.

**Blanch.** Immerse the vegetables in hot water. Time the scalding starting from the moment the water returns to a boil. (The time needed to blanch a food is given under the entry for that food in this book.) Add 1 minute to the blanching time if you live 5,000 feet or more above sea level.

**Chill after Blanching.** Immediately after the blanching is completed, remove from the hot water. Sometimes I put larger vegetables directly into the kettle of water, as you do with corn on the cob. When they are blanched, I fish them out with 2 potato mashers, one held in each hand. Smaller vegetables are fished out with a sieve, which then holds them under cool running water from the sink faucet. The ideal procedure is to put the blanched vegetable into an ice bath or to cool in a colander under a stream of cool running water until you have its temperature down as low as possible. The immediate chilling reduces as much as possible the period of lukewarm temperature during which the bacteria quickly build their numbers. The thicker the vegetables, the harder it is to get them frozen (beets and whole carrots take longer than peas, for example), so you should have them cooled as much as possible before packaging. The only exception to chilling before freezing is if you're working with only a small amount that you can put in small packages for the freezer to cool.

**Sample Blanching Procedure: Peas**

a. Put shelled peas in the colander and sink colander, peas and all, in the boiling water.

b. Leave it there just long enough for the water to return to a boil. Then start counting. If it takes longer than 2 minutes for the water to boil again, you're trying to blanch too much at once. You can time the vegetable or do it by experience. When the peas change color, they're ready—"blanched."

c. Lift out the colander full of peas and let it drip a moment. Immerse in a first bowl of ice water. Stir with your fingers to help it cool.

d. In a minute or two move it to a second bowl of ice water.

e. When the peas are thoroughly chilled, drain, package and put in freezer. You'll have terrific-tasting peas using this system.

5. **Pre-Treatments for Fruits:** Fruit can be packed for freezing without a sweetener or a liquid. Fruits that will be eaten raw or used for pies or jams after thawing will be fine without a sweetener. Just slice or crush in them in their own juice, or even freeze them whole.

**Anti-Oxidant Treatment.** To prevent discoloration of light-colored fruits and other deteriorating effects of oxidation, fruit can be briefly soaked in a solution of ascorbic or citric acid (or a combination of the two)—about 1/2 t. per 1 qt. water. Or some lemon juice can be added to their water. You can buy the acid at any grocery or drugstore under a trade name.

**Sugar and Syrup Packs.** Fruits deteriorate in color, texture, and flavor less quickly if packed in a sugar or syrup pack than if frozen unsweetened.

**Pectin Pack.** Fruit is frozen in a syrup made by mixing powdered pectin, sugar, and water. Combine 1 package (1 1/4 oz.) powdered pectin with 1 c. water. Boil 1 minute, stirring. Add 1/2 c. sugar and stir until dissolved. Remove from heat. Add enough cold water to make a total of 2 c. syrup. Cool before using.

**Dry Sugar Pack.** Just mix sugar and fruit until the sugar dissolves in the fruit juices. Use 1 part sugar per 4 or 5 parts fruit, measured by weight. Or sprinkle 1/2 c. sugar per 1 lb. fruit.

**Honey Pack.** Honey will work if your freezer faithfully stays at 0°F or below. If the temperature gets higher, the honey is likely to crystallize.

**Syrup Pack.** The fruit is prepared for freezing by immersing it in a sweetened syrup. Syrups may be called light, medium, or heavy, depending on how much sugar they contain. A light syrup is made by mixing 2 c. sugar with 4 c. water. A medium syrup is a mix of 3 c. sugar and 4 c. water. A heavy syrup is 4 1/4 c. sugar and 4 c. water.

6. **Package:** Use vapor-resistant or vapor-proof packaging materials. Package in such a way as to remove as much air as possible and seal the package airtight. Be sure to label the outside of the package with the date and name of what's inside! I like to package in plastic bags because it saves...
freezer space. Paper containers with only a thin layer of wax, and the thinner plastic bags and wraps, are not suitable containers.

**Plastic Boxes.** Best are plastic containers that are intended as freezer containers. You should be able to seal the cover airtight. You can use waxed cardboard cartons (cottage cheese, ice cream, or milk cartons) only with a polyethylene bag liner, because alone they are not moisture/vapor-resistant. If you put a plastic bag inside the plastic freezer boxes before you pour in fruit, the fruit keeps better and the outer plastic container lasts better. You can use regular zip-top plastic bags from the grocery store for this. Don't use hard plastic containers such as cottage cheese, yogurt, or margarine tubs at all—or at least only with an inside bag—because they tend to crack at low temperatures.

**Jars.** The best jars for freezing are wide-mouthed freezer jars with straight sides. The best shape for rigid glass or plastic containers is square, so they fit close together and don't waste freezer space. To pack food into a wide-mouthed container, allow ⅛ inch headspace at the top for pints, 1 inch for quarts. If it's a narrow-mouthed container, leave ¼ inch headspace for pints, ⅛ inches for quarts. This is to allow for expansion of the liquid while freezing. You can freeze in nonfreezer-proof jars if the contents will be relatively loose and dry rather than liquid.

**Bags.** The non-rigid containers that you can use are boilable plastic bags and plastic freezer bags. Boilable bags are constructed of heavy-duty, food-safe plastic that can handle both cold and heat. (If you are using boilable bags, you can blanch, cool, freeze, and later cook the vegetables, all right in the same bag.) Polyethylene film and bags are good for freezing. You can get them at grocery outlets. For freezing, it's best to use only plastic bags labeled "food safe." I bag all my vegetables. If the bags aren't sturdy, especially when holding peas and beans, I pack them into a larger, stronger plastic freezer bag. A chicken will fit into one big bag.

**Freezer Wraps.** We wrap other meats with butcher paper ("laminated paper" or "locker paper") fastened with freezer tape. Your butcher can tell you how to get such paper if your grocer can't. Or you can wrap in polyethylene or Vinylidene chloride film (Saran) sheets. Heavy-duty foil ("locker"- or "freezer"-grade) is another option, though I dislike putting aluminum next to food. Regular kitchen waxed paper is not enough protection for long-term freezer storage. When using a wrap, press it around the food to shut out as much air as possible. You want your package to be moisture/vapor-proof. The best wrap is the one that is most tightly sealed. To package food using rolled material, cut it to size, wrap around your food in about three layers, press to get out all the air, and seal with freezer tape.

**Sealing Boilable Bags.** Seal by placing the top of the bag on the small, heated sealing strip inside the bag sealer. Some bag sealers and bags are designed to use a continuous-roll bag that you custom-seal to whatever size bag the situation calls for. There are various brands of bag sealers, such as the Oster Automatic Bag Sealer, Dazey Seal-A-Meal, and Krupp vacuum sealer, all modestly priced. Or you can seal by filling the boilable bag, laying it on a heavily padded board, covering the bag with a damp cloth, and sealing the open edge using an electric iron at its low setting. This is more trouble than the regular bag sealer, but it works.

**Foods Containing Free Liquid.** For foods that are mushy or runny, you'd appreciate something sturdier than a plastic bag. You could line with a plastic bag a tin can, an odd-sized jar that can't be used for canning, or a jar with a chipped rim. (The bag also makes air space in the bottom of the jar that prevents the jar from breaking when the frozen liquid expands.) Pour in the liquid and close off at the top. Leave 1 inch headspace in glass jars, ½ inch for plastic containers. Freeze it in the upright position; once frozen, it can go any which way. You can also freeze using freezer jars. In that case, pour the food in your jar, put on the lid, and screw the hand down tightly. That is probably the best freezer container because it's an airtight, leakproof, moisture-proof, odor-proof container. Be sure and leave headspace at the top to allow for expansion during freezing.

**Vacuum Sealing.** Vacuum sealers for individual users are a recently developed product. You can buy them at Costco for $250 or so.

NOTE: After you vacuum-seal food, it must be refrigerated and eaten soon—or kept frozen or canned. Otherwise, vacuum-sealed food can kill you from botulism, just as underprocessed canned food can! People see shrink-wrapped foods in the store that are keeping well and assume all the package did was wrap them. But those foods were packaged and sealed and then heat-processed, much like canned foods!

**7. FREEZE:** Speed is important! Quick freezing minimizes ice-crystal formation and spoilage.

**Secrets of Speed Freezing**

1. Twenty-four hours before you're going to be doing a major freezing project, turn your freezer temperature to -10°F.
2. Small packages freeze faster than big ones.
3. You can freeze food most quickly by spreading it out on a tray and putting it in the freezer. When frozen, gather up the food and bag it for long-term storage. Not only is this style quick, but you can also freeze food loosely so that a little can be removed at a time rather than it all coming out in one big frozen hunk.
4. Put the packages of unfrozen food right next to the freezing plates or coils in the coldest part of the freezer. Or place unfrozen food against the freezer wall, and in a single layer across the top of your freezer, with space between packages. After they’re frozen you can rearrange for long-term storage.
5. For big quantities, you can quick-freeze in a locker and then bring home to your freezer.
6. Once the food is all frozen, turn the freezer back to 0°F.

**Freezing a Lot at Once.** The bigger your freezer is, the more food it can handle freezing at once. But don't overwhelm it. The manufacturer's booklet that comes with the freezer will tell you the maximum amount that you can freeze at one time. If you have half a beef, perhaps it would be best to take it to a locker for quick-freezing first. The more unfrozen food you put into a freezer at once, the longer it will take the machine to get it frozen. Worse, having a bunch of warm food in there may raise the temperature of the frozen food already in there. It's more at risk than the fresh food, because frozen food whose temperature increases can quickly spoil. So be conservative in adding new food—in general no more than 2 to 3 pounds of food per cubic foot of freezer space. For example, a 16-cubic-foot freezer should not have more than 35 pounds of unfrozen food put into it in one 24-hour period of time.

</table>

It's best to use all frozen foods within a year, and most of them in less time. These recommended keeping times for frozen foods are based on quality loss. You could have a turkey in there for 14 years and, if it never defrosted, it would still be safe to eat, though not very tasty.

### Using Your Freezer

#### Long-Term Food Arrangement:
I try to arrange food in up-and-down columns so I always have something of everything on top. Meat takes up a lot of room, so it goes on one whole side, with the vegetables and fruits on the other. When I have only a little of something—like packages of butter, cream cheese, or bread—it goes into the baskets on top so it doesn't get lost down among the rest.

#### Records:
It's a good idea to keep an inventory taped to the outside of your freezer of what's in there. It should be a list of all the food inside and when you put in each item. That will help you plan meals and use food within its recommended storage period. Cross off items as you take them out. 

#### Deterioration of Frozen Foods:
Each bag holds the amount we would use at one meal. That isn't always the same, though. As the year wears on, it takes larger portions of the frozen food to satisfy our hunger. Even when it still looks and tastes good, your frozen food is losing some food value and you have to eat more to get your hunger satisfied. Over the months, the frozen vegetables and fruits slowly but steadily lose taste, texture, and nutritional value. There is a big difference in the green beans, for some reason. What that means is that in the early spring, when cooking and serving, you have to serve—and eat—a bigger portion of those beans (or other frozen foods) in order to get the same amount of nutrients as you did when you first froze them in the fall. The “Freezer Storage Times for Good Quality” table gives guidelines on how long different kinds of foods will keep.

Deterioration of frozen foods can come from four sources: growth of low-temperature microbes; “freezer burn,” which means dehydration and oxidation from air contact; ice crystals, which puncture cell walls, turning food into mush; and those ripen-then-rot enzymes doing their thing.

#### Microbes:
Yes, some microbes are functional at even below-freezing temperatures, and they can reproduce even in the freezer, although very, very slowly. At that low temperature, mid- and high-temperature microbes can't grow at all, and even the low-temperature-specialist beasties can't grow very fast. They may double in number only every couple months instead of every few hours, as they would outside the freezer.

That growth of low-temperature bacteria is why food, even in the freezer—especially rich, moist foods like ice creams and gravies—will indeed slowly but eventually “spoil,” although it takes 1–24 months depending on the food and the freezer. To keep low-temp bacteria under control, it really matters what temperature your freezer is set at.
and whether it remains constant or fluctuates up and down. To keep bacteria almost perfectly inactive, the food has to stay at 0°F or lower. Anything warmer, even for a while, is a marvelous window of opportunity for those cold specialists.

**Freezer Burn.** If your container isn’t securely closed, the food will, over months, dehydrate and deteriorate. You can see freezer burn on the food; it will look kind of faded and dried.

**Mushiness.** Frozen water inside the food forms tiny ice crystals that can puncture cell walls. You know that has happened if, when the food thaws, the juices run out and the food seems mushy. But the faster the food freezes, the smaller the ice crystals will be; that helps preserve your food quality. Partial thawing and refreezing double the cell damage and diminish food quality that much more.

**Enzyme Deterioration.** If your vegetables aren’t blanched or your large fruits aren’t packed in syrup, the action of natural ripen-then-rot enzymes inside them will cause undesirable changes in color, flavor, and food value.

**WHEN YOUR ELECTRICITY GOES OFF:** When you have a freezer, there is always the nightmarish possibility of the power going off. For sure, sooner or later it will, or the freezer will break down. Plan what you will do when that happens. Locate a nearby freezer-locker plant or a place that sells dry ice. Your only other emergency option is to can or dry the food immediately as an alternate preservation method. The food would lose some, but certainly not all, of its quality in the processing.

1. If you know ahead of time about a possible or certain upcoming power loss, turn your freezer to the coldest setting. The colder it is to start with, the longer it will stay cold without electricity.
2. Keep the door closed!
3. Cover the freezer with blankets, except for the motor vent openings if there’s a possibility the power might turn on again (that could overheat the motor if the vents are covered).
4. The more full your freezer is, the longer it can hold out without electricity. Food in a full freezer will stay frozen for about 48 hours without electricity, but food in a half-full freezer may keep only 24 hours; a quarter-full one, only 12.
5. If the power is likely to stay off longer than your freezer will stay frozen according to Step 4, wrap it in blankets and/or newspapers and move it to a locker. Or . . .
6. If you know where you can buy dry ice and if you can get it fairly soon after the power failure, 25 pounds of it would keep a full 10-cubic-foot freezer below 32°F for 3 to 4 days. Fifty pounds would do the same for a 20-cubic-foot one. If the freezer is only half full, the ice will keep it below freezing only 2 or 3 days. But you have to get the dry ice in there as soon as possible, before the contents have started to thaw. Don’t open the lid if you can help it, to avoid letting out the cold air. NOTE: When working with dry ice, don’t put it directly on the packages. Lay a piece of heavy cardboard on top of the food packages. Put the dry ice on top of that. Wear gloves! Don’t touch the dry ice with bare hands. After that, open the freezer door only to take out food or add more dry ice.

**WHEN POWER RETURNS: SAVE/TOSSE WHAT?** Food that still contains ice crystals has not gotten warmer than 40°F. If there are no ice crystals left in the food, it is technically “defrosted.”

**Bread Products.** Even if defrosted, these can be re-frozen.

**Cooked Foods.** Do not refreeze any dishes containing meats, fish, or poultry.

**Fish and Shellfish.** Never refreeze these because they spoil very, very easily; also, they normally stink, so you can’t use their smell as an indicator of dangerous spoilage.

**Fruits and Fruit Juice.** Even if defrosted, they can be re-frozen (or canned or dried). There will be loss of quality. If fruits didn’t thaw out completely and still have some ice crystals in them, they will refreeze without much loss of quality. Concentrated juices can be refrozen. They will lose quality, though, and may not reconstitute as well. Plain fruit juices will probably refreeze fine.

**Ice Cream.** Do not use.

**Meat.** Do not refreeze cooked meats. When my raw meat has thawed partly but not “defrosted,” I’ve refrozen it and then used it up as soon as possible thereafter. It looked and smelled fine, and I gave it a very thorough cooking to make sure. But any meat that thawed and didn’t look and smell fine, I gave to the animals. Spoiled meat looks and smells odd. “When in doubt, throw it out!” Technically speaking, if the meat has not heated above 45°F, it should still be fine.

**Vegetables.** If vegetables get even a little thawed out, they really go downhill fast—much faster than fruits. When this happens to me, I just throw them to the chickens or pigs. Or you can compost them. The experts agree: Don’t re-freeze them.

**DEFROSTING THE FREEZER:** Our electricity has never been off long enough to matter. What invariably happens is that some child pulls the plug and it takes me a day to find out, although I try to maintain an unconscious habit of glancing at that light that indicates the freezer is on as I go by. This seems to be a spring phenomenon, so I haven’t yet had to set up a special time for cleaning out my freezer. When the accidental spring thaw comes, I just say “Praise the Lord” and very quickly finish emptying the freezer. Then I wash it clean, plug it back in, put back in what I dare, and threaten the children with horrible vague happenings if they ever do that again.

If I don’t defrost accidentally, then I defrost on purpose once a year. Ideally, you should defrost every time as much as ½ inch of frost builds up over a lot of the inside of the freezer, and when frost starts to collect even on packages stored only a few hours. Frost buildup is a problem, but taking all that food out of its protective cold can be viewed as even worse. The ideal time to defrost is in early spring, when the freezer is getting toward its emptiest and before the new produce is ready in the garden. The frost has to be gotten rid of for several reasons. It acts as an insulator, preventing heat inside the freezer from getting removed by the condenser coils. The more frost you have, the less space you have. It also tends to absorb and hold foul odors. And the more frost you have, the more electricity the freezer must use to maintain its coldness.

**Steps to Defrosting**
1. Turn off the electricity.
2. Move the food to another freezer or to a well-insulated situation, wrapped in blankets and/or newspapers.
3. Scrape off what frost you can using a wooden or plastic (not metal!) scraper.
The above warnings are given because when you freeze foods, you don’t kill the beasties; you just put them to sleep. So it’s important to thaw and cook the food in as fast a sequence as you can. Foods that have been frozen, especially vegetables, are subject to very fast deterioration once thawing has set in. For vegetables, I peel off the baggie and put the frozen hunk directly into a little boiling water. I serve as soon as it is thawed and hot. I drain the cooking liquid into the gravy or the pig bucket. Put a big glob of homemade butter on the vegetables and serve.

I thaw frying meat in the refrigerator on the morning I plan to use it. Frozen roasts and roasting meats, like ribs, are put into the oven still frozen. It takes about 1½ times the usual cooking time if the food starts out frozen. It takes a while to thaw a quart of frozen stuff like stew. I put it in a pan of lukewarm water and very, very gradually raise the water temperature as the contents of the jar start to liquefy. Never plop a jar of frozen food directly into hot water. Glass containers are likely to crack if exposed to sharp changes in temperature.

Improving Thawed-Out Stew. When I reheat a thawed-out stew, I usually add some fresh vegetables from the root cellar or garden to make it taste better.

Stir-Fried Frozen Veggies. Melt 1 T. butter per serving in a cast-iron frying pan. Add your frozen veggies. Stir-fry in hot pan until the water has evaporated and it’s done enough.

Long-Stored Green Beans. When string beans are in really bad shape, I can make them most palatable by putting the icy hunk directly into a frying pan with a little bacon grease or a smear of oil. I stir them as they thaw, adding a few previously fried onion chunks or green spring onions out of the garden (the top-set onions are ready by March).

Long-Stored Meat. It will be dry and of poor flavor, but you can still get use out of it. Cook it well, and cook it in a soup or sauce to mask the off-flavor.

CANNING

A favorite neighbor of mine, Imogene, is about 60 years old. One of her arms is sort of paralyzed from a childhood case of polio, and she sees only well enough to read newspaper headlines. She lives on about 3 acres with her husband, who has been a total invalid with a bad heart condition for several years now, and with her widowed mother, who doesn’t get around too actively due to arthritis. She was not blessed with children. Imogene milks goats and has a big garden. Of all the families I know, hers comes closest to living totally off their own produce.

But the important thing about Imogene is that she is the most cheerful, friendly, giving person I know—I’d even risk saying “in the whole world.” She’s always got a big smile and a sincerely happy-to-see-you “Hello!” She loves company on any day but her precious Sabbath, which she withholds for rest and prayer, as she feels God wants her to. Seems like she’s always calling me up wanting to give me something—a big sack of carrots and another of spuds or some such. I’d rather eat Imogene’s vegetables than my own. Hers are raised with such love there just have to be more vitamins in them!

When the fruit is ripe in our orchard I can from morning to night using 2 big enamel water bath canners. It keeps me moving because as soon as I have loaded with fruit and juice the 8 jars that each canner will hold, it’s time to take out the last batch and load in the new ones. That’s because of the handling involved in getting the fruit ready—like washing, picking out the leaves, and pulling out the stems for cherries. When I can every day, even only 4 or 6 quarts, I have a lot of jars by summer’s end. But many days I can more than that.
the house. If you have to can in the house, how can you cope with the extra heat? Especially if you are choosing to do without air conditioning anyway, which many fine people are doing as an eco-sound choice, even in the South. So if you are able, use a summer canning kitchen and do your summer cooking, especially canning, out there so you don't have to heat up the house. Basically all you need is a stove, even just a stove top, plus some counter space for working. Of course, it would be wonderful to have a screened-in outdoor kitchen equipped with water and electricity.

The Science of Canning

Drying and salting were the basic preservation methods until Nicholas Appert, a French baker, tried cooking food in tightly corked glass bottles in 1809. Napoleon had asked Appert for a system to preserve food for his far-flung troops. Appert continued his experiments for 15 years. His basic system was to put food in a widemouthed glass bottle, close it with a cork stopper, and then heat in boiling water 5 hours or more. Some of his jars kept and some spoiled, but Appert's efforts proved that heat treatment of a sealed container could preserve the food inside. That was the beginning of canning.

The heat kills beasties that are invisible to the naked eye. But they're there, everywhere, always: in your water and air, on all the surfaces around you, on the food, and especially in the soil in which it grows. There are 3 types of invisible competitors for your food: molds, yeasts, and bacteria. They are present either as the adult form or as seed, or "spores." The spores are tiny, very tough particles that, when dry, float up into the air and travel thus. When they happen to land on something edible, their life cycle starts again.

You can clearly see when you've got a major crop of mold on something. Bacteria aren't visible in the same way. Like molds and yeasts, there are many different kinds of bacteria that could make a home in your food. Some bacteria thrive at a low temperature and are a problem in your freezer. Some are most comfortable in middle-range temps. For canners the important bacteria are the "thermophiles," which actually reproduce contentedly at a range of 130-150°F and whose spores can handle boiling awhile and still be okay. That's why you have to be so careful when canning.

Five basic factors are involved in safe canning: number of microorganisms in food to start with, density of the pack, acidity of the food, canning temperature, and processing time.

1. NUMBER OF BEASTIES: The more beasties your food contains to start with, the more heat treatment it takes to eliminate them all. So start with fresh, unspoiled food. Remove any spots of decay. Wash food thoroughly in clean water. Chill freshly killed meats and poultry immediately after killing, and keep them chilled until canning.

2. DENSITY OF JAR CONTENTS: I know home canners who long to can in half quarts or gallons for the efficiency of it. But they don't, because it isn't safe. Heat during canning travels inward toward the center of the jar. The last place in the jar where the beasties die is in the center, because that's the last place to heat up. If the center doesn't get hot enough long enough, the contents will spoil. A factor in how long it takes to kill all the beasties in there is the nature of the jar contents. Pure fluid is the easiest to heat up and heat through, so juice is easy to can. A loosely packed food heats much faster than a jar whose contents are tightly packed, so green beans with liquid between them heat much faster and easier than a solid pack of squash. And a jar whose contents have a liquid cover heats through more quickly than one without, so that's why the liquid covering the food in your jar is there. The densest foods, and thus the slowest to heat, are corn, meat, and "dried" beans. Foods like apples and pears are loosely made and conduct heat easily and quickly through to the center.

3. ACIDITY OF THE FOOD: The more acid a food is, the less heating time is required to destroy bacteria. The pH is a way of measuring that acidity. The standard pH scale uses the number 7 to mean the neutral point. Foods with a pH smaller than 7 are more and more acidic as the pH number gets smaller; foods with a pH above 7 are more and more alkaline as pH gets larger. The "pH of Foods" table tells you the pH of some common foods; every food has some pH.

* Researchers at Washington State U. discovered that the acid content of tomatoes ranged this much and depended on the climate where they were grown as well as on their variety and ripeness.

As you see, tomatoes are the lowest in acid of the high-acid foods, so they deserve special care. Pickles are high-acid because of all the vinegar in them. Salsas and taco sauces need the same processing times as tomatoes. "Hotness" of a food doesn't protect it from spoiling. Acid content is why fruit and other high-acid foods may be canned using a water bath, but vegetables and meat must be pressure-canned for safety.

4. CANNING TEMPERATURE: The standard canning instructions are that foods from tomatoes on up through plums can be processed at 212°F; but that foods from okra on down must be processed at 240°F—meaning in a pressure canner, which is the only way you can get them that
A pressure canner is supposed to get up to 240°F. The rules before they croaked. Boiling, of course, happens at 212°F whether you put the food into the jars pre-cooked and still because the hot-pack precooking is figured into the process. Last year [1976] in the United States, there were 20 reported incidents of botulism involving 30 persons and resulting in 7 deaths. One death from botulism is one too many, because they could all be prevented by following proper canning procedures. In this new edition I've painstakingly given you only the safest procedures, and the canning instructions scattered throughout the book have all been reviewed by true experts (which I am not) and either approved, changed so as to be approved, or dropped.

**HOW BOTULISM GROWS:** Botulism poisoning is caused by a certain kind of bacteria (*Clostridium botulinum*) that is practically everywhere in the soil. The food poisons specialists call the beastie “bot” for short. You’re safest, and most likely correct, to assume that bot is present on your garden food too. The bacteria themselves are not poisonous. But it’s a good idea to keep your baby out of the dirt because children under age 1 don’t handle them as effectively as older people do. Bot won’t grow in the refrigerator. When cooked, bot bacteria die easily, but their seed forms, called “spores,” are extraordinarily resistant to heat. They aren’t resistant to high acid and sugar, however; those inactivate the bot spores. (We’re beginning to learn that botulism can survive in mildly acid products.) That’s why high-acid foods, sweet preserves, and pickled foods can be canned using a boiling-water bath.

But if bot spores get a combination of insufficient heating, no air, low acid, and low sugar content, then they are in bot heaven. The area inside a sealed jar is a no-air place. And if it isn’t jam or pickles or fruit, it’s a low-acid food. In that case, you have to pressure-can. That extra heat is the only remaining line of defense. Bot spores can resist a lot of boiling, but they are reliably killed by the 240°F temperatures achieved by heating under pressure—“pressure canning.”

### 5. LENGTH OF PROCESSING TIME

The higher the temperature, the shorter the time needed to kill those tough spores. For foods with a pH of 7, for example, one test showed the spores could endure boiling for 330 minutes before they croaked. Boiling, of course, happens at 212°F. If the temperature was held at 220°F, they could hold out only 100 minutes; at 230°F, 33 minutes; at 240°F, 11 minutes. A pressure canner is supposed to get up to 240°F. The rules allow it a little margin for error.

Old-timers used to can meats and low-acid vegetables using the water-bath method, boiling for as long as 6 straight hours, before pressure canners were invented that could achieve the higher temperatures. Because a lot of things can happen in 5 or 6 hours, including a temporary drop in temperature you don’t know about, to say nothing of the waste of fuel energy, that long-cooking method is no longer recommended for low-acid vegetables. On the other hand, water-bath canning is still very desirable for high-acid foods, because even in a water bath, their processing time can be faster than waiting for a pressure canner to heat up and then cool down again, and just as safe.

Whether you do “hot pack” or “raw pack,” meaning whether you put the food into the jars pre-cooked and still hot or uncooked and still cold, affects your processing time. If hot pack is specified, it’s important to process that way, because the hot-pack precooking is figured into the processing time. Hot pack is also beneficial because the food shrinks, and you’ll get more into every jar. And the pre-cook releases air, which helps your seal.

### About Botulism

**OF CANNING, BARGAINS, AND SAFETY:** Canning is a bargain compared to buying store food. Being a frugal-minded person, in previous editions of this book I used to look for ways to make canning even cheaper. No more. I understand better now the risk of botulism. Over 700 people have died of botulism since folks started canning in this country. (In 1992 in the United States, 10,000 persons were killed by handguns, which puts that in some perspective.) Last year [1976] in the United States, there were 20 reported incidents of botulism involving 30 persons and resulting in 7 deaths. One death from botulism is one too
low-acid foods, the remaining spores grow. As they grow they give off an invisible, tasteless, but powerful toxin (poison).

**"Bot" Toxin:** This toxin is one of the most deadly poisons known on earth. If you merely touch a finger to it and touch that finger to your lips to taste, you could get enough to kill you. It is said that 16 ounces of bot toxin would be enough to kill the entire world's population. The toxin itself doesn't trumpet its presence. You can open the jar and it may look and smell fine. It is, however, destroyed by heat. That's why it is recommended that all low-acid home-canned foods be boiled 15 minutes with the lid on before tasting or serving.

The symptoms ordinarily appear within 18 to 36 hours of poisoning but have been known to take as long as 8 days to become evident. What are the symptoms? At first nausea and vomiting, later blurred vision, dry throat, and difficulty swallowing. Then comes progressive weakness that can paralyze the respiratory tract as well as the limbs. The poison does that because it affects the nervous system, breaking down communication between motor nerves and the muscles.

The botulism cases that I've heard about involved pickled beets, tomatoes (for which pressure canning has not in the past been recommended), spicy tomato products such as salsas and taco sauce (the problem being the false assumption that the "hotness" will preserve the food), mushrooms, olives, asparagus, beans, cabbage, carrots, and peppers. In rare cases, it has also happened with pressure-canned food.

Researchers are just now discovering that bot bacteria can survive in the presence of more acid than had previously been believed. Some standard canning directions used to say to simply bring pickled beets, for example, to a boil and then hot-pack them. Some people got bot poisoning from doing that. Now we know it's not safe to can pickled foods without a water-bath canning time. So therein lies the risk of using old recipes. Some cooks thought that because salsa was so hot, it could be canned without much processing. Again, now we know better because of a bot case. Spicy hot doesn't bother bot.

Now that I've practically scared you to death, let me revive you with success stories. Many's the family that cans 700 or more quarts a year, year after year, with great success. Florence Ward, Quilcene, WA, wrote me, "I have canned for over 50 years. When we lived on a dairy ranch for 17 years, I used to can around 600 quarts of fruit and meats each year. Pickles too. We had five children—all married long since. Fruit, such as peaches and apricots, cherries and pears—I've canned thousands of quarts of them."

Sandra Oddo, Hurley, NY, wrote me, "A year ago I got a pressure canner from Sears for $24 (can 4 quarts, hold 8) and now I wouldn't be without it. It's too small for mass-canning, but perfect for what's left of the lentil soup after we've had a ham—canned soup heats faster than frozen, too—and for food deliberately mass-cooked so there will be leftovers for pressure canning, which saves later work. It saves enormously on fuel. Would you believe that 45 minutes turns a 3-year-old rooster into a tender stew?"

From Maureen Darby, Leslie, AK: "The cost of the canner is easily offset by the fact that it requires far less fuel to operate than it would to can in boiling water. I even can fruit under pressure. I do have to watch it closely, but it's better than waiting to boil the quantity of water needed to cover the jars in a water bath. We don't own a freezer. The initial cost and the cost of the electricity to run them make them impractical—besides the constant worry of power shortage."

So be careful when you can. But bot poisoning is rare—an average 7–30 cases a year nationwide among about 100 million canners. It's rare because of all the careful home canners who read the rules that come with canning equipment and in good canning books, and follow them, and use pressure canners. Still, that's 7–30 too many sick people. Those safety rules are all very clearly stated here, too. Please, better safe than sorry. Follow them!

### Canning Methods and Supplies

Get ready for your food preserving ahead of time, because when the harvest is on you'll be frantic. Good supply sources for home canners:

- **Cumberland General Store:** 800-334-4640.
- **Gardener's Kitchen** (old-fashioned no-phone lifestyle; great lids and prices); PO Box 322, Monument Beach, MA 02553; gkitchen@cape.com; www.gardenerskitchen@cape.com.
- **Home Canning Supply** offers a free catalog: 800-354-4070; 760-788-0520; 1815 La Brea St., Ramona, CA 92065; sales@homecanningsupply.com; www.homecanningsupply.com.
- **Lehman's Non-Electric:** 888-438-5346; www.lehmans.com.

### Books

**NOTE:** Recent discoveries about canning safety mean that no canning recipe from an old book (including older editions of this one!) can be fully trusted. Get your canning recipes from up-to-date sources. Until recently, all canning recipes were based on USDA research completed in 1942. In 1986 the USDA asked Pennsylvania State University to repeat that old research to double-check their results. By 1990 they were finished, and the news was out that there were numerous errors in the old research.

Current canning recipes are in recent books or university extension bulletins. For a free booklet, "Home Canning Made Pure and Simple," write Consumer Products Co., PO Box 2005, Muncie, IN 47307. This company now owns and markets both Ball and Kerr (another disgusting example of complete marketplace monopoly, the trend). For answers to food preservation questions, or to order the Ball Blue Book Guide to Home Canning, Freezing and Dehydration ($6), call them at 800-240-3340.

### SUMMARY OF METHODS:

Here's a basic summary of methods to illustrate what supplies you'll need. You'll either be doing water-bath canning or pressure canning—or both, depending on what foods you choose to can. The old-time "open-kettle method" is no longer recommended, even for jam making! Jams are now processed 5 minutes in a water bath. Paraffin is no longer recommended for sealing them because it isn't considered reliable enough—just use a regular jar lid!

**Water-Bath Canning.** James R. Coffey, Elkton, MD, wrote me that it's "known as cold packing in my area." Water-bath canning is only for fruits and high-acid tomatoes, not for vegetables or meats. Water-bath canning preserves food because the prolonged heat combined with the high-acid content of the food effectively kills botulism and other bacteria.
For water-bath canning you need jars, lids, rings, a canning kettle, a rack, and a jar lifter.

You put the prepared fruit is in sterile, clean jars, covered with water or syrup. Then you put the lid and ring on and tighten. You lower the jar(s) into your kettle of boiling water. You need a perforated rack in the bottom of the pot for the jars to rest on. This ensures that they won't break if they sit on the bottom of the kettle itself. The water needs to be able to move freely around the outside of the jars. The kettle must be tall enough so that water will cover the jars by at least 1-2 inches at all times. During long boilings, have another kettle boiling nearby from which you can add water as necessary. Once the correct amount of time has gone by, remove the jars with a jar lifter. Set them on top of a towel or wooden board on your counter to cool. You start timing when the water comes to a boil again.

Pressure Canning. This method works to preserve low-acid foods such as vegetables and meats because low-acid foods have to be heated to at least 240°F in order to kill any botulism spores present that enjoy a low-acid environment, can live indefinitely through mere boiling, and thrive in the oxygen-free environment of a sealed jar.

To do pressure canning, you need jars, lids, rings, a pressure canner, a rack, and a jar lifter.

Follow the recipe for the food preparation. Put on the softened lids and rings. Set your canner on the heat with the lid off, with 1 to 2 inches of water in the bottom of it, to start heating. Make sure the rack is in there. Set the jars onto the rack in the pressure canner. Put the lid on. The water boiling in the canner will cause steam to escape from the vent on the lid of the canner. Once the steam release is constant, start timing and wait 10 minutes. By then all the air will have been removed from the inside of your canner. Shut the stopcock, or put your weight on. Watch the canner gauge. Wait until it shows the correct pressure has been reached (usually 10 lb. for low-acid foods and 5 lb. if you're canning high-acid foods, but a little more if you live at a high altitude—see “Altitude Adjustments for Pressure Canning” table later in this chapter). Now start timing your canning process.

Once the processing time is over, take the canner from the heat. Let it cool naturally and slowly. (The natural cooling time is part of the recipe!) When you're pressure cooking, you can run water over the canner to cool it quickly, but don't do that when pressure canning. The manual for your particular canner will tell you how to know when the canner is cooled. Once it is cooled, open the canner lid. Remove the jars using a jar lifter.

Canning Jars

Getting Jars: If you plan to can, get your jars, lids, and screw bands ahead of time. You can buy new canning jars at big grocery outlets, but they're not cheap. Nathan D. Justus, Fair Haven, NJ, wrote me, "For one dozen quart jars in my area, it costs approximately $8, but I feel this is inexpensive, particularly since the jars can be reused many times, if they are treated with proper care." It's best to buy them by the case a year ahead of time, since stores sometimes run out at the peak of the season. Or look (or advertise) for used canning jars, usually a good bargain.

How Many? How many jars you need depends on how large your family is, how much of your preserving is by canning, and how many months a year of fresh garden produce you can grow. If you put up 100 quarts of green beans, your family could eat 2 quarts a week all year round; the same for corn or fruit. So you can figure out what you think you'll need. An average family of 4 in an average climate might want to can 300 quarts. Alice Flanigan, Blackstone, IL, wrote me of her neighbor with a family of 7 who cans 700 quarts a year.

You can also refer to the "Canner's Planner," the USDA's attempt to take the guesswork out of planning for the coming year. In the Planner, the phrase "36 weeks" means that item is canned only for the out-of-season weeks of the year. The Meats category assumes you also have 10 other servings of meat, poultry, food-from-water, or eggs. A sizable old-time family with no meat preservation system other than canning, no modern refrigeration, and lots of animals on the farm canned as much as 400-500 quarts of meat per year. (Canning made it possible for them to have meat besides chicken in the summer months.) Any individual family will want some variation on this estimate based on their family's personal preferences.

What Type Jars? The size jar you want depends on how much your family can eat at a meal. For my family, it works best to put up butters, jams, jellies, and taco sauce in half pints to minimize spoilage before that food gets used up. All stews, vegetables, and fruits go into quarts. (It is possible to can your family's most loved high-acid fruit in half-gallon jars—but only high-acid fruit.) Pint jars are best for ketchups and vegetables, except string beans and tomatoes, which do well in quarts. You'll have a choice of regular jars, widemouthed jars, can-or-freeze jars, and jelly glasses and jars.

If you wonder whether a jar is the right size for canning, test it with a screw band. If one of the three sizes will fit, it's okay. The glass isn't quite as heavy as in regular canning jars, but if you are careful that the food you put into the jars is hot or has hot water or juice poured over it before you put it in the hot canner, it won't break.

NOTE: Don't use antique canning jars, either the zinc-lidded jars or the old 2-piece glass-lid type, because their seals are not dependable, and replacement rings are getting impossible to find.

On the other hand, wonderful fancy jars are available from The Cook's Garden (800-457-9703; www.cooksgarden.com) and other outlets. They offer stylish glass...

</table>

**Avoiding Jar Breaks.** Glass expands with heat and contracts with cold. If you pour something hot into a cold jar, the inside might expand enough to crack the outside, and blooey—food all over your table and no jar. When working with glass jars, keep that in mind. But you already knew that, I'm sure.

**Widemouthed Jars.** The widemouthed jars are good for large whole fruits, such as peaches and pears, and for meat and pickles. They are easy to fill and clean because you can get your hand inside for thorough washing, but the lids are a little more expensive.

**"63" Jars.** The "63" jars (small size) are hard to fill, especially for hot-pack canning. Very liquid items like juices, or small fruits such as cherries, berries and apricots, go into them best.

**Recycled Mayonnaise Jars.** The cheapest way to get jars is to have everybody save their mayonnaise jars for you. I know that numerous other writers say this is awful. But I have the assurance of Jan Grant, King County extension agent and founder of the Master Food Preserver program, who carefully reviewed all the contents of this book, that there is no safety problem with these jars if all your other procedures are correctly followed. However, these quart and pint mayonnaise jars should be used for *only water bath—not pressure—canning* because they aren't as sturdy as regular home canning jars. And use them only if you use a regular home canning-type Ball or Kerr lid set, *not the store lid, with them*.

**Avoiding Jar Breaks.** Glass expands with heat and contracts with cold. If you pour something hot into a cold jar, the inside might expand enough to crack the outside, and blooey—food all over your table and no jar. When working with glass jars, keep that in mind. But you already knew that, I'm sure.

**Lids:** Brand-new metal jar lids are reasonably priced and are virtually your only expense when you're canning garden produce and already have the jars. So don't even consider reusing jar lids. They are made to work only once. Make sure the lids you buy will fit the jars you have. There are 3 standard lid sizes: "63" (which is small), "regular," and "widemouthed."

**Screw Bands:** These come in the same 3 sizes as the lids. Match the sizes! Screw bands, like jars and unlike lids, can be used over and over—unless they get bent. If a screw band is rusty or bent, it can prevent a safe seal. Throw away bent screw bands and use new ones.

**About Reusing Lids and Screw Bands.** Actually, you can reuse them if you are canning only high-acid fruits. That's because you never have to worry about botulism with high-acid fruits. As F.E. Pennington of Kelso, WA, wrote me, "Who cares how rusty the rings are? They never touch the product. And if you hold a bunch of lids together, you can detect any bent lids. They can be used as new as new lids—that is, the Ball dome lids. Reusing does not work well with Kerr lids. I get at least a 90 percent seal."

**Utensils for Canning**

**Funnel.** A widemouthed canning funnel is available from kitchen specialty stores and homestead mail-order outlets. If you don't have one, you'll wish you did, because you'll be...
always burning your fingers. They also prevent spilling, so the jar rim stays clean. They are especially necessary for hot-pack canning.

**Soup Ladle.** You can use a cup, but you're less likely to burn your fingers using a ladle if you're filling jars hot-pack style. F. E. Pennington says, "I find a funnel a nuisance. I ladle the fruit into the jar."

**Slotted Spoons.** Big spoons with long narrow holes inside are wonderful for lifting fruit out of a dip, and so on.

**Canning Tongs.** This tool is valuable for lifting lids and empty hot jars out of hot water.

**Jar Brush.** This is used for cleaning inside regular (narrow-topped) jars.

**Hot Pads, Mitts, Heavy Potholders.** Use so you don't burn your fingers.

**Jar Lifter.** You need this to get the hot jars out of the hot water. It closes around the jar and tightens as you lift. No risk of dropping hot jars with this! A funnel, jar lifter, kitchen tongs, lid lifter, and jar wrench are available as a set from The Cook's Garden (800-457-9703; www.cooksgarden.com).

**Tin Cans:** Seems like everybody knows somebody in Alaska who cans in real cans. (The rest of us are actually "jarring,") Lane Morgan says, "I have friends in Alaska who do subsistence fishing. They can lots and lots of salmon and they use commercial-style cans, not jars. I think they like the cans because they use the canner space more efficiently. I don't know how they put the lids on. They can their salmon with a teriyaki marinade and it really is sensational. Their other meats—mostly moose and bear—they freeze." People who can in metal fill the can, seal it, and then toss the can into boiling water and leave it there, boiling non-stop, for the designated number of hours. This method is the most common one used in commercial canning, but the equipment is not easily available to home canners. The cans are actually made of steel plated with tin or enameled on the inside. The can and lid are supplied as separate items, and you need a special can sealer. You can't reuse metal cans, and they're much more expensive than jars.

**NOTE:** When using metal cans, do not use procedures or processing times given here.

**Water-Bath Canning Kettle:** These come in 22- to 26-quart sizes (which hold 4 or 6 quart jars at a time) and aren't expensive. The kettle is enamel and equipped with a jar-holding rack to keep jars on the bottom of the pan. Hardware and kitchen stores have them. But actually, any container large enough to hold jars covered with boiling water can serve as your water-bath canning kettle. You can make a big canner out of an old-fashioned copper washtub. Put it on 2 burners at once. It will hold 16 quarts at a time. You can get a stainless-steel canning-size kettle from Lehman's; 888-438-5346; www.lehmans.com. You can use a pressure canner as a water-bath canner if you don't fasten the cover down and are careful to leave the petcock wide open.

**Steam Canners.** Steam canner manufacturers have never done the very expensive testing necessary for USDA approval, so this cannot be an extension-recommended method. However, if all you can in it is high-acid fruit, you may end up with spoiled fruit, but nothing that can kill you. But you may safely use a steam canner in place of a water-bath canning kettle only to can the most high-acid fruits, because this method does not kill critters as dependably as a regular boiling-water bath. You especially can't use it in place of a pressure canner!

One model resembles an upside-down pot. There is a shallow bottom pan with a tray over that. Your jars of fruit go on the tray. Water goes in the pan. The tall, tightly fitting top covers the jars and holds in the steam from the heated water. Don't let it boil dry.

**NOTE:** A microwave oven cannot be used for canning because it doesn't heat evenly enough.

**Pressure Canner:** These cost more than the other items on this list, but it's a one-time cost because they last a lifetime, and you absolutely must have one to can low-acid foods. A pressure cooker is not the same as a pressure canner. Incidentally, follow the manufacturer's instructions for proper washing and care of the pressure canner after using it. Be careful not to nick or chip its sealing edges.

**NOTE:** Pressure canners are potentially dangerous. Make sure a manual comes with yours. If you lose the manual, write to the manufacturer to get another one.

**Dial Gauge vs. Weighted Gauge.** When shopping in many outlets, you'll be asked to choose between a "weighted-gauge" and a "dial-gauge" canner. They are both safe, good canner types. The dial-gauge pressure canner is nice for high-altitude canners because it can fine-tune adjustments of pressure, even as little as ½ lb. It's also quieter than the weighted-gauge style. But you have to take in the dial gauge every year to be tested for accuracy, and it must be watched to maintain pressure. Being more complex, it also has a few more parts to get lost.

**NOTE:** When the Penn State canning research was done, they discovered that in a dial-gauge canner, the ideal temperature of 238-240°F for killing bot was achieved not at 10 but at 10.5. So it is now recommended that everyone see a recipe that says "10 lb. pressure," you should actually use 11 lb. if you're using a dial-gauge pressure canner. On the other hand, the weighted gauge is manufactured to reach the 10.5 pressure even though set for 10. Based on that research, the weighted gauge is safer and preferable. In addition, its accuracy is guaranteed for the lifetime of the product.

The weighted-gauge style of canner, on the other hand, has an annoying, noisy nature and adjusts pressure by only
5 lb. at a time. On the good side, it's simple to use, has fewer parts, doesn't need to be tested every year because it cannot be made inaccurate unless the weight is damaged (very unlikely and hard to do!), and doesn't have to be constantly watched. But I prefer the weighted-gauge type. You can train yourself to recognize what its noises are saying, and it allows you freedom to do other things while canning. However, high-altitude canners who need added pressure may be wiser to choose the dial-gauge style.

James Coffey of Elkton, MD, a very serious home canner, wrote me, "I have 2 water-bath canners and 2 pressure canners. I prefer the dial gauge for most canning, but I use weighted gauge for tomatoes especially. I am a baker by profession and can at home as a hobby and to save on the food bill as well."

Sizes range from 7-qt. liquid capacity (holds only 4 pint jars for canning) up to the 22-qt. size, which holds 20 pint jars, and the 30-qt. size, which holds 19 pint or 14 quart jars. Lehman's also sells pressure canner parts such as knobs and gauges. Secondhand canners are a bargain and have been a blessing. But they can also be big trouble. Make sure yours comes with a little booklet about burns and explosions, unless it's identical to your other one or you can write to the manufacturer and get the right manual for it.

**Gasket.** Your old pressure canner needs a new gasket if steam persistently escapes around the rim and pressure fails to build up. An overdue gasket either may get hard and slippery or may stretch and no longer fit easily and well.

**Hard Water?** If your area has water so hard that it leaves a mineral deposit on the outside of jars, add Vi c. vinegar to each cannerful of water to prevent that.

### Twelve Life-Saving Canning Rules

Canning low-acid food is the only preservation method that can be deadly, so with canning instructions you must follow the rules closely and not experiment. You will hear from people who insist that they canned food in less time or with methods that are not recommended and haven't died of it. Because so many factors enter into what makes food safe, with good luck you might be able to get away with it for a long time. But then again, that luck could run out at any time, and the unthinkable of botulism poisoning could occur. These canning instructions are designed to always provide you such a wide margin of safety that poisoning is simply impossible. You follow the directions, and then you can be confident.

*Learn and follow these rules absolutely!*

1. Don't use jars larger than a quart. Home canning technology cannot guarantee that larger quantities will be sufficiently heated through for enough time. Rather, the food on the outside will overcook, while that on the inside won't get hot enough. Botulism spores can boil awhile and still be fine.

2. Use water-bath canning only for high-acid foods. High-acid varieties of tomatoes, fruits, rhubarb, sauerkraut, pickles, and jams/jellies are the only high-acid foods. All others (vegetables, meats, stews) must be canned using a pressure canner.

3. Use only modern canning recipes from reliable sources.

4. Never reuse jar lids. Used lids aren't reliable for sealing correctly. If a screw band is rusty or bent, it won't work right and should be discarded and replaced.

5. Don't use antique or "French"-type canning jars. They aren't as safe as the modern, regular (Ball, Kerr) type.

6. Check the jar rims carefully every year by running your finger over the top of the rim and checking for nicks. Even the tiniest nick makes a jar unusable for canning. A nicked jar rim won't seal reliably.

7. Raw pack is not safe for certain foods: beets, all kinds of greens (spinach, etc.), white potatoes, squash, okra, a tomato/okra combination, and stewed tomatoes!

8. You must allow the correct amount of space (head-space) between your food, together with the liquid that covers it, and the jar lid.

9. Don't begin counting the processing time until after the water with the jars in it comes to a good rolling boil if using the water bath method, or until after steam has vented for 10 minutes from your pressure canner.

10. Process the full recommended time. If canning on a wood stove, watch your fire carefully to make sure it stays hot. If your boil or your pressure fails at any point in the process, you must start over and reprocess for the entire recommended time.

11. Lift out each jar individually (not inside the rack) using a jar lifter; keep it upright and not tipped.

12. If a jar didn't seal, discard the lid, put on a new one, and reprocess. Or put the jar that didn't seal in the refrigerator and use the contents within a week or so.

### General Canning Instructions

This section explains the canning process. First you prepare and pack the food; then you process it using either a water-bath method or a pressure-canning method; and then you cool the jars and store them. (And finally, if all goes well, you eat your good canned food!)

**Preparation and Packing**

1. Run your finger around the rim of each jar to check for nicks. A nicked rim can't be depended on to seal properly.

2. Wash jars in hot soapy water till clean. If you can't get jars hot enough, put them in a big kettle of hot water two-thirds full, and put it on to boil. You need a very big, hot burner or a very hot stove top to can with.

3. Use only modern canning recipes from reliable sources.

4. Never reuse jar lids. Used lids aren't reliable for sealing correctly. If a screw band is rusty or bent, it won't work right and should be discarded and replaced.

5. Don't use antique or "French"-type canning jars. They aren't as safe as the modern, regular (Ball, Kerr) type.

6. Check the jar rims carefully every year by running your finger over the top of the rim and checking for nicks. Even the tiniest nick makes a jar unusable for canning. A nicked jar rim won't seal reliably.

7. Raw pack is not safe for certain foods: beets, all kinds of greens (spinach, etc.), white potatoes, squash, okra, a tomato/okra combination, and stewed tomatoes!

8. You must allow the correct amount of space (head-space) between your food, together with the liquid that covers it, and the jar lid.

9. Don't begin counting the processing time until after the water with the jars in it comes to a good rolling boil if using the water bath method, or until after steam has vented for 10 minutes from your pressure canner.

10. Process the full recommended time. If canning on a wood stove, watch your fire carefully to make sure it stays hot. If your boil or your pressure fails at any point in the process, you must start over and reprocess for the entire recommended time.

11. Lift out each jar individually (not inside the rack) using a jar lifter; keep it upright and not tipped.

12. If a jar didn't seal, discard the lid, put on a new one, and reprocess. Or put the jar that didn't seal in the refrigerator and use the contents within a week or so.

**General Canning Instructions**

This section explains the canning process. First you prepare and pack the food; then you process it using either a water-bath method or a pressure-canning method; and then you cool the jars and store them. (And finally, if all goes well, you eat your good canned food!)
this method. If you have trouble with your water boiling down in a water-bath canner, keep an extra pan of water boiling on your stove and add boiling water from that to the canner.

5. Put a pan that holds about a gallon of water on to boil to make your canning liquid.

6. Follow your recipe for food preparation. You’ll find canning instructions for specific vegetables and fruits under their entries in Chapter 4 and Chapter 6, respectively. You can add or omit salt in any canning recipe as it suits you; it will not affect the processing time except for brined pickles, where salt content is critical for safety!

The food to be canned should not have bruise spots or decay and should be as freshly gathered as possible. If you can manage 2 hours from garden to jar, you’ll be a wonder and have the best-tasting canned food possible. Be especially careful not to let any dirt into the jar or food mixture, because bot bacteria live in soil. Thoroughly wash all food to be canned. The best results come from washing small batches at a time under running water, or in and out of several changes of water. Lift the vegetables out of the water so that any dirt gets left in the bottom of the pan. But don’t soak the food, because then it loses vitamins and can get soggy. Scrub root vegetables especially well.

Here are more fruit-canning hints and options:

• To easily remove the skins of tomatoes and some fruit, drop them into boiling water for a minute or so, until the skins peel off freely.

• To prevent discoloration when peeling large, light fruits for canning, keep them in a brine (2 t. salt per quart of water, or 2 T. salt and 2 T. vinegar per gallon water). Remove the fruit within 15 minutes. You can not worry about darkening and just work fast, which is what I do; keeps down the salt intake.

• To prevent darkening and loss of vitamins, add ascorbic acid (a form of powdered vitamin C). Use ⅛ t. powdered ascorbic acid per quart of fruit. Mix it in with the water/syrup that will cover the fruit in the jar.

For other fruit pre-treatments, see the “Freezing” and “Drying” sections on fruit pre-treatments.

7. Fill your clean jars with the fresh-cut food, leaving at least ⅜ inch headspace (see Step 9). Food can be packed raw in the jars (called “raw pack”), or the food and its liquid can be preheated first and then ladled hot into hot jars (called “hot pack”). For packing instructions for the specific vegetable or fruit you’re canning, see its entry in Chapter 4 or Chapter 6. For a quick reference, see the tables “Packaging High-Acid Foods for Water-Bath Canning” and “Packaging Low-Acid Foods for Pressure Canning Only.” If packing halved large fruit, pack it with the inside down to get the proper headspace.

If you are canning juice, tomatoes, or something else that doesn’t need liquid added, skip the next step and go to Step 9.

8. Prepare canning liquid by adding sugar, honey, or a combination to hot water. Sugar helps fruit hold its shape, color, and flavor, but you don’t have to add it to safely preserve food. You may can food in plain water or use much less sugar than the usual recipe says. Or you can use a honey solution, can in fruit juice, or use no sweetening or water at all! Refer to the table “Standard Syrup Mixtures” for suggested combinations. See “Freezing” section for syrup recipes. Or you can add sugar directly to hot-packed juicy fruit. Use ⅛ c. per quart of fruit, heat to simmering, and then pack.

For info on honey canning, see You Can Can with Honey by Nancy Cosper. Or use plain hot water. Sorghum, molasses, or brown sugar are other possible sweeteners but are less preferable because they tend to overwhelm the flavor of the fruit.

After mixing the ingredients for your syrup, heat and stir until in good solution.

*Any combination of water and juice (from the fruit you’re canning or from another kind) OK.

9. If hot packing, pour liquid over the fruit in the jars. Leave enough headspace between the food and the jar lid. Too little headspace doesn’t allow the food inside room enough to expand when hot and boiling during processing. Too little headspace can result in liquid being forced out of the jar during processing, and a failure to seal. Usually your recipe says how much headspace to leave. But here are the guidelines that recipe writers follow: Jellies, fruit syrups: ¼ inch headspace Jams, preserves, pickles, relishes, syrups, juices: ⅛ inch headspace Canned fruits: ⅛ inch All meats, poultry, fish, and low-acid vegetables (except limas): 1 inch

Lima beans: 1¼ inch (pints), 1½ inch (quarts)

10. Release any air trapped in the jar by running a thin flat plastic or wood (not metal) utensil around the side of the jar. This will cause air bubbles to come to the surface. A thin plastic spatula works perfectly for this. (Metal may crack or chip the jar.) Be especially careful to get the bubbles out if you have a product that has been in a blender. You do this because trapped air can emerge later and ruin the seal. Add more water if needed to maintain the proper headspace.

11. Wipe clean the rims of your jars before putting on lids. Use a wet cloth for syrupy contents, a dry cloth if there may be fat droplets.

12. Get your lids ready by heating them to simmering in a pan of water. Then remove from heat. Don’t let them boil.

13. Put the flat metal lid on the jar, “composition” side next to the glass. Screw the metal band on over it. Screw down firmly by hand. Don’t use a jar wrench for screwing down bands because lids must be loose enough so air can escape in the canner.
If you are water-bath canning, proceed by the following directions. If you are pressure canning, skip to “Pressure Canning Procedure,” which follows “Water-Bath Canning Procedure.”

**WATER-BATH CANNING PROCEDURE**

1. Load your jars into your rack. (You can load jars with the rack either inside or outside the canner, but when it’s time to take them out, leave the rack inside the canner and take the jars out one by one to avoid accidents with boiling water.) If you loaded outside the canner, holding the rack by the two handles, lower it into your canning kettle. Adjust the water level so that it is at least 1 inch above the tops of the jar lids. Work quickly enough so that your jars are still quite hot from the hot liquid being poured in; otherwise, they may crack when they hit the boiling water. (Commercial jars, like mayonnaise jars, crack more easily than regular canning jars.)

2. When the water in the kettle returns to a cheerful boil (don’t confuse the bubbles of air escaping from the inside of the jars with a boil), start timing and boil it the recommended processing time, being careful that it never drops below a boil, in which case you’ll have to start your timing all over again. The “Processing Times for Water-Bath Canning” table shows how many minutes to boil various high-acid foods. If you live more than 1,000 feet above sea level, adjust the processing time as indicated in the “Altitude Adjustments for Water-Bath Canning” table.

**PRESSURE CANNING PROCEDURE**

This is the bot-safe method for canning low-acid foods: meats, poultry, fish, and vegetables (except rhubarb and tomatoes). Technically you can also pressure-can fruit, and some people do. But the canning times are so short that most people think a pressure canner is a pure nuisance to use for canning fruit, because fruit requires only about 8 minutes or less of pressure canning, and it gets frustrating to wait for the thing to heat up and then cool down so you can get on with the next batch. That’s why we prefer to can fruit water-bath-style.

**NOTE:** If you have a dial-gauge canner, have the gauge tested every year before canning even one batch! Call your cooperative extension office to find out where to get this done. Even a brand new one must be tested before use, since shipping can make it inaccurate. When your canner lid is tested, you’ll also get information about any recommended changes in time and pressure and procedure of canning.

Now skip to “Cooling, Storing, and Using.”

1. Put wire basket in your pressure canner.
2. Follow instructions for your particular size and style of canner as to the amount of water to put in—probably enough to cover the bottom 1 to 3 inches deep, maybe 1 or 2 quarts. Read the manual. Follow its instructions. You have to keep your mind on a pressure canner! They can be very dangerous!
3. Put filled jars with tops screwed on into canner on the wire basket. (Setting jars directly on canner bottom will break them.)
4. Put lid on pressure canner and screw on until it is tightly closed.
5. Check petcock valves with a toothpick if you haven't used the canner lately; if you have that style.
6. Turn up the heat. Watch for the steam—when you hear it, start timing. Watch for a steady flow of steam coming from the vent for 10 minutes. This is air leaving the jars and canner. It's called "exhausting" or "venting" the canner. You want the air trapped in the canner to escape through the petcock or steam valve. If the canner isn't properly exhausted, the air will cause the reading on the gauge to be inaccurate, and your canning temperatures may be too low to be safe.
7. After the canner has exhausted for 10 minutes, close the vent or place the weight control over the steam valve.
8. Watch for the pressure gauge to reach the correct pressure for your altitude (see the "Altitude Adjustments for Pressure Canning" table). Then set your timer or look at the clock and begin the designated processing time, as shown in the "Processing Times for Pressure Canning" table. If you are processing food in jars of a half pint or smaller, use the time listed for pints.

9. Adjust your heat source so the gauge stays at your determined temperature. If it's showing a higher temp, turn down heat a little. If lower, turn up heat. If you have a gauge that has to be watched, turn it so you can keep an eye on it as you do your other work in the kitchen.
10. When the jars have been processed the correct amount of time, take the pressure canner off the heat (use dry potholders or heavy towels) and let it cool. Let the pressure go down of its own accord. Don't try to rush it. On the average it takes 45–60 minutes for the pressure to go down in a pressure canner.
11. The steam and heat inside even a "cool" canner can be dangerous. Wait until the pressure gauge has gone down to zero, or until steam isn't visible rushing out when the regulator is nudged (with a pencil or long-handled fork, not your finger!). You will hear a hissing sound whenever you nudge the regulator, but if you don't see steam, it's ready for you to remove the lid.
12. When you can see no more steam, first open the petcock or remove the weighted gauge (not with your fingers!). Open the petcock valve slowly. Let the canner cool further. Then unlock the canner lid. Slide lid across the top of the canner toward you, thus letting steam escape from the far side of the canner. Leave lid sitting loosely on top of the canner for two more minutes. Remove canner lid. Take your jars out after 10 minutes. If you leave jars in the canner too long, they may not seal and they may overcook.

### Cooling, Storing, and Using

1. For proper sealing, the jars must be removed from the water while still hot. Use your jar lifter to take out each jar one by one. You should use a jar lifter because it helps you keep them upright as they are moved from canner to cooling place. This is a dangerous time. Have the children out of the way of scalding hot drips. Don't wear shoes with slippery soles.
2. Set jars aside to seal on a surface warm enough that they won't crack because of a temperature contrast—a board, a cooling rack, or several layers of newspaper or towels—not a cold surface. Turning jars upside down is no longer recommended, for jam or any other food. Leave a couple inches between them for air to circulate. Don't cover them. Don't tighten the lids. That could break a seal which has already formed. Let them finish sealing on their own.
3. The beginning of the cooling causes a vacuum to develop inside the jar that sucks the lid down tight. You can often hear the pleasant "ping" popping sound as it seals. Test for the seal when the jar has cooled off. Most seal almost immediately, but some seal a little later on.
The sealing takes place when airflow between the jar and the outside is cut off. The air inside the jar contracts because it is cooling, so you have a vacuum effect inside the jar, which pulls the lid downward and reinforces the seal.

You can sometimes tell whether or not the jar is sealed by looking at the lid. You can feel the seal too, the downward-to-the-center (concave) curve of the lid. Whether the lid moves when you press it down is also an indicator. If it stays down when pressed, the jar is sealed. But if the lid pops back up, it's not sealed.

Some lids have a "safety button" in the center. When this button is flat, the jar is sealed. If it is popped up or later pops up, the jar is not sealed, or the seal has broken.

And you can hear it! If it is sealed, you'll hear the difference for sure if you tap it with a fork or spoon. A sealed lid makes a clear ringing sound when tapped with metal because of the tension on it. The only exception to this would be if the jar is too full and food is touching the lid. Then you can't know if it's sealed so must assume it is not, because it wouldn't make the canner's famous and beloved "ping." If the lid is not sealed, the sound is lower-pitched and not musical or prolonged. After you've heard the difference a few times, you'll never mistake it. (However, hearing isn't as reliable as seeing and feeling the seal.)

If a jar does not promptly seal after processing, re-process for the full canning time using a different lid, or leave off the lid, put jar in fridge, and use within a week. But reprocessed foods will be distinctly overcooked.

4. Let sealed jars cool undisturbed 18–24 hours. Don't move them or tighten the rings any more because that can cause the seal to be broken.

5. After at least 18 hours have passed, take off the rings (screwbands) so liquid under them won't cause rusting. Wipe any stickiness off the outside of the jars. Label them with type of food and date.

6. Store in a dry, cool, dark place. A root cellar or regular cellar is ideal. You have to store the food someplace where it can stay cool but can't possibly freeze. Freezing would break your jars as the water expands. In general, the cooler the storage, the better the quality retention. Leaving at least ½ inch headspace in the jar protects it from freezing to a certain extent but not entirely. That's why canned food should be stored together with root vegetables in your root cellar, if you have one. Otherwise it needs a cool, dark place such as a basement. The coolness helps hold down enzyme and microbe activity in stored food, and the dark helps protect the color. If you live in an earthquake-prone area, canned food arranged on shelves is very vulnerable to the slightest tremor. In that kind of area, store canning jars in boxes flat on the floor, with cardboard strips as cushions between the jars. When you run out of floor space, use strongly attached shelving with edging strips to prevent the jars from falling off.

7. When you open a jar, check for signs of spoiling. Do not taste if you have any doubts. If you don't hear air rush in, that indicates it was not sealed; discard it. If the cap bulges upward or the food has a strange smell or look, don't taste it; discard it. Some bacteria produce "flat-sour spoilage"—sour spoilage with no gas—in canned goods. Some cause gas formation, and you get a bulging lid. Spoilage can make food either more acid or more alkaline, depending on the beastie. Some, such as botulism bacteria, leave no sign of their presence at all—no taste or smell—but nevertheless make the food poisonous.

On the other hand, if the underside of your metal lid has turned dark, don't worry about it. The natural acids and salts in certain foods can interact with the metal and create those harmless brown or black deposits under the lid. They are not harmful to you.

8. If in doubt, throw it out. Don't throw it to the animals, because if there is really bot toxin in there, it would poison them. The USDA says, "Due to the risk of botulism, low-acid and tomato foods that are not canned according to . . . USDA . . . recommendations should be boiled before eating, even if you detect no signs of spoilage. Boil foods for 10 minutes at altitudes below 1,000 feet. Add an additional minute of boiling time for each additional 1,000 feet elevation. This is because bot toxin breaks down when heated. Boiling it covered gives you a higher temperature in the pan. If a canning procedure is not USDA-recommended, it says so in this book. If you followed the recommended processing times and all the rules, if your pressure canner was in good condition, and if the pressure gauge was accurate, your food is safe."

But I repeat, if in doubt, don't taste it; don't try to salvage it by boiling; just throw it out.

How Long Will Canned Food Keep?

Safety is one measure. Quality is another. As long as your seal lasts—which can be for years—canned food is safe to eat. But every year it sits on the shelf, you lose quality. You lose color, texture, taste, and nutritional value even though it's still safe to eat. With the passage of years, jars may lose their seal and the contents truly spoil, although they can last surprisingly long.

I think the best way to proceed is to plan so you eat up during the winter everything you canned the fall before. That way you can eat from your garden in the summer and from your garden via your various food-preservation systems, including canning, during the winter and have all
your preserved food of the very best quality. If you manage correctly, you’ll polish off the last jarful as the new garden is starting to produce.

May 18, 1976. I’ve been writing this book for 6 years now. I don’t have a baby anymore. Sara just had her third birthday, and Luke is 4. Becca is ready for the first grade next fall, and Dolly will be 12 in a few weeks. Danny is a dignified young man of 8. This seventh edition has been a long time coming, longer than any of the others. This year and the year before, it seems like I’ve done everything but write. Last summer was my first attempt at a School of Country Living. Afterwards I had a lot of bills to pay.

I went back on the road with all 5 children and me living in the van and going from town to town all around the whole United States. Julaine was setting up appointments for me from Los Angeles, and we kept in close touch on the telephone. Darlene, Diann, Ivy, Kay, and the crew back at the Living Room Mimeographer in Kendrick were standing by to make and mail the books they hoped I’d create orders for. Mike was lonesome at home taking care of the big zoo of domesticated animals we had developed for the School and the stock cows that were to eat the grass crop. I didn’t get on any big national shows because I wasn’t that important, but Julaine could generally get local TV, radio, and newspaper interviews for me in the smaller towns, where big-star types didn’t bother to go.

So I’d do about 5 cities a week, working all day. A typical day would be maybe 2 TV shows, 2 radio shows, and a newspaper interview. I’d get done about four o’clock and then in the evening drive a few hundred miles to the next town, with laundromat and grocery store stops as needed. We were so desperate for money to pay the bills I’d run up over everyone’s dead body, trying to make my School go, that I just couldn’t ask them for money back in Idaho. So I literally peddled my way. When I had a live show, I’d suggest that folks could meet me at the public library or a downtown park or some such, and I’d show them my books for sale and pictures of the School and pass out my free brochures. When I got low on both gas and cash and had no live interviews, I’d set out with a couple of books and newspaper interviews for me in the smaller towns, where big-star types didn’t bother to go.

Many a morning I washed my hair in the sink of a TV station bathroom before the show. The plumbing plugged up in the van, and all through the Midwest we stunk worse than a load of upset skunks. And we practically died of asphyxiation from the fumes when I ignorantly mixed ammonia and lye trying to clean the toilet. Finally we completely quit using the thing, and it composted naturally and was done. I was grubbier and tireder as every day went on. “Sparkle, Shirley!” I’d remind myself as the lights came on. And in true show business style, I’d sparkle through the show as best I could and then drag myself back to the parking lot.

But now the poor old van was getting sick. And without Mike, who had always changed my tires and oil and fixed engines for me, I was helpless. I barely made it through the Holland Tunnel, and the engine died at the intersection of Sixth Avenue and something-or-other street right in downtown Manhattan. I gave my next-to-last dollar to some fellows to push it out of the intersection onto the curb. Somebody stuck their head in the window and asked, “What are you going to do?”

“I’m going to sleep,” I answered.

He looked dumbfounded. I was too tired to care. It was the middle of the night and I’d been fighting that engine all afternoon. It had taken me 3 jump starts with long waits between to get into New York City, where I had a show to do the next day. I crawled in the back and we went to sleep. In the middle of the night, somebody tried to crawl in a window of the van. When I raised myself up and stared at him, he looked more scared than I and ran away. I went back to sleep.

The next day there in New York City, we got to do the “To Tell the Truth” show, and that was a good respite. They fed us and bought us a room in a fine hotel. The children bounced on the beds and played in the bathtub and drove the hotel staff crazy. There was only one other show to do in New York, because nobody else had wanted me. That was a sort of blessing, for on the whole this trip was much busier than the one before had been.

**ROOT CELLAR STORAGE**

Root cellar storage keeps vegetables and fruits fresh (live!). And because of the cellar’s coolness, they keep longer. It also protects your live foods, and jars of canned food, from freezing if you live in a cold zone.

Planning for this type of storage starts with planning your garden. You plant foods that store well in a cellar. Beets, late cabbage, carrots, celery, parsnips, potatoes, sweet potatoes, salsify, and turnips can be stored without canning, freezing, or drying in a root cellar. Carrots and potatoes in particular may stay crisp and nice until May. So you don’t need to can late fall apples, onions, and big winter squash.

To make it easier on the food preserver in the family and reduce dependence on electricity and the availability of jar lids, do fresh vegetable storage. If you want to do this, plant a larger portion of your garden with these kinds of foods.

My cellar is my favorite room in the house next to the kitchen. (Well, in wintertime I also love that big bed in our
bedroom with all the thick quilts that I hate to rise from on cold mornings.) The walls are lined with shelves, on which rest the canned goods plus all our typical needs. I try to shop only once a month and buy things ahead as much as I can, so when we need something I can head for the cellar rather than the store.

On the floor are the pickle crocks, jugs of vinegar, cooking oil, honey and so on. On a wooden platform on the floor are cans of oatmeal, flour, and wheat. The deep freeze is in another part of the basement. But not everything can be kept in our basement because it doesn’t have a dirt floor, and that’s bad for vegetables. And in winter it’s too hot for them once we have the furnace going.

More Info: Root Cellaring by Mike and Nancy Bubel (1979) is a treasure of a book. It covers everything—how to store vegetables and fruits, recipes, etc.—but its strong point is its presentation of a multitude of various root cellar designs. There’s a good article on this in Backwoods Home Magazine, Nov/Dec. 1992. On the web, see www.postharvest.com.au for an Australian website with postharvest handling and storage info and links to other sites. And or NC 27695-7603. Or read them online at www5.bae.ncsu.edu/programs/extension/publicat/postharv/index.html.

### Storage Places

You can store vegetables and fruits in an attic, unheated basement room, cellar, outdoor pit, etc. To figure out what food to store where, use a thermometer to learn temperatures. Any place that is dependable 32–60°F can be used to keep some kind of food; the temperature and humidity of each location determines which kind. A room 4 x 4 x 6 feet is large enough for most families. A room 6 x 7 x 7 feet will hold about 30 bushels of produce—5 bushels per month for 6 months. An 8 x 10 x 7-foot room will hold about 60 bushels of produce—10 bushels per month for 6 months.

A Warm Attic: In the fall, dry herbs, beans, walnuts, or hickory nuts here.

Pantry or Unheated Room: This is good for short-term storage of potatoes and long-term storage of onions, spices, vegetable oils, nuts, and commercially canned foods. Low storage temperatures extend the shelf life of dried foods such as dried beans, herbs, dried fruits and vegetables, coffee, flour, rice, pasta, and cereals. Be careful that the room doesn’t get below freezing.

For Root Vegetables, Cabbages, Apples, Pears: These need very cool, moist conditions. They store well without refrigeration in basements, cellars, outbuildings, and pits, but then you need cool outdoor air to provide the refrigeration. The kind of storage place you need depends much on your climate. Typical root cellar instructions assume outdoor temperatures during winter that average 30°F or lower. You can make do with a combination of cellar, attic, and outbuildings, but nicest of all is to have a “real” root cellar. A proper root cellar can be a

</table>
little building sitting by itself or adjacent to another building, or it can be a real dirt cellar under an outbuilding. It should be near the house because you will be going there a lot in very cold weather and you don’t want a long hike. **NOTE:** Don’t store live food in or near a garage, unless it is wrapped so that it will be fully protected from car emissions, which produce will absorb.

**Heated House Basement:** A well-ventilated basement under a house with central heating generally is dry and has a temperature range of 50–60°F. It is fine for ripening tomatoes and for short-term storage of pumpkins, winter squash, potatoes, sweet potatoes, and onions.

**Insulated Basement Storage Room.** To store vegetables and fruits over winter in a basement that has a furnace, you would have to partition off a room and insulate it from the heat source. Build the room on the north or east side of the basement, if practicable, and don’t have heating ducts or pipes running through it. You need at least one window for cooling and ventilating the room. Two or more windows are desirable, particularly if the room is divided for separate storage of fruits and vegetables. Shade the windows in a way that will prevent light from entering the room. Equip the room with shelves and removable slatted flooring. These keep vegetable and fruit containers off the floor and help circulation of air. The flooring also lets you use water or wet materials (such as dampened sawdust) on the floor to raise the humidity in the room. It’s safest to store vegetables and fruits in wood crates or boxes rather than in bins, although my friend Imogene winters her carrots all in a big barrel and they do fine.

**Cellar Under House Without Central Heat:** Cellars under houses without central heat have long been used successfully for winter storage of fruits and vegetables in colder parts of the United States. These cellars usually have an outside entrance and a dirt floor. The door is a means of ventilating the cellar and regulating the temperature. Some cellars have no windows. If there is a window, it aids in ventilation and temperature control. If the cellar has separate compartments for vegetables and fruits, then you need at least two windows, one for each compartment. Shade the windows in a way that will prevent light from entering the cellar. Light causes potatoes to turn green and become bitter. Insulate the ceiling so cold air will not chill the house.

**Out-of-House Storage**

**In-Garden Storage:** It is possible to leave some root crops, such as carrots, turnips, and parsnips, in the garden where they grew, for part or all of the winter. Parsnips, horseradish, and turnips actually get a better flavor after light freezing—between 28° to 34°F—because that cold causes their starch to change to sugar. After the ground begins to freeze in the late fall, cover the root crops with a foot or more of mulch—straw, hay, or dry leaves. Do not place mulch on warm soil, because doing so will cause vegetables to decay rapidly. Wait until the ground is cold. Root vegetables can be hard to dig out of the frozen ground, but will not be harmed unless the temperature around the roots gets down to 25°F or lower. Carrots are damaged at about 25°F; but parsnips can stand lower temperatures. But if rodents are a problem, it is wiser to store these in a buried closed container or in a rodent-proof indoor storage area. One gopher can chop away a whole row of carrots.

Certain other cold-hardy crops such as beets, cabbage, Chinese cabbage, cauliflower, celery, endive, cos or romaine lettuce, kale, leeks, and onions can endure the early light frosts and can be stored in the garden for several weeks more under a heavy mulch. (See growing details in Chapter 4.)

**Pits:** Foods that need a cold moist place (see “Live Storage Guidelines” table) can be stored outdoors. An advantage of pits is there’s no buildup of rot spores, as there may be after a year or two in a cellar. But any outdoor storage has the disadvantage of sometimes being inconvenient or impossible to access, and rodents and other beasts may come to share. Pick a site that is well-drained so it doesn’t collect water. You need lots of insulation to protect the food from frost and fluctuating temperatures. People use straw, hay, dry leaves, corn stalks, wood shavings, and plain dirt for insulation. (Dirt is best as a layer over other insulation.) Be sure your insulation isn’t contaminated with chemicals or pesticides. Pits should be made in a different place every year because leftovers in used pits are contaminated.

**Buried Can.** One type of pit is made simply of a wooden barrel covered with several layers of straw and dirt. Or you can use an insulated wooden box or ice chest (but not a plastic “garbage” can!), buried in the ground. This makes a convenient and cheap storage place for your vegetables. Metal cans are most rodent-proof. The opening of the can should sit about 2 inches above ground level. Make sure the container hasn’t held anything that would poison or give an off flavor to the food. *Never use drums or containers that might have held pesticides or other chemicals.* Make several holes in the bottom to allow drainage. Dig your hole deep enough so you have room for a layer of rocks in the bottom of it for drainage. Set the can on top of the rocks. The vegetables go into the can in layers with straw or other mulch between each layer. Cover the top of the can with a mound of insulating material that is at least 1 or 2 feet deep and that extends at least a foot on each side of the can.

**Cone-Shaped Pits.** Cone-shaped outdoor pits are often used for storing potatoes, celeriac, kohlrabi, rutabagas, winter radishes, carrots, beets, turnips, salsify, parsnips, and cabbage. They are sometimes used for storing winter apples and pears. The pit may be built on the ground or in a hole 6 to 8 inches deep in a well-drained location. Build the pit as follows:

1. Select a well-drained location.
2. Spread a layer of straw, leaves, or other bedding material on the ground at least 3 inches thick. Or dig a shallow hole 6–10 inches deep; this gives better frost protection (but increases the risk of water collection). Lay insulation in the bottom of the hole.
3. Stack the vegetables or fruits on the bedding in a cone-shaped pile up to 12 inches above ground level. Don’t store apples and pears in vegetable pits, for they’ll pick up odors.
4. Arrange them around a beanpole that will stick up through the top of the mound, high enough to be seen through snow cover, so you can find your food in winter.
5. Cover the vegetables or fruits with more bedding.
6. Cover the entire pile with 3 or 4 inches of soil.
7. Firm the soil with the back of a shovel to make the pit waterproof.
8. Dig a shallow drainage ditch around the pit.
9. Small pits containing only a few bushels of vegetables or fruits will get sufficient ventilation if you let the...
bedding material over the vegetables extend through the soil at the top of the pile. Cover the top of the pile with a board or piece of sheet metal to protect the stored food from rain; a stone will hold the cover in place. To ventilate large pits, place two or three boards or stakes up through the center of the pile of vegetables or fruits to form a flue. Cap the flue with two pieces of board nailed together at right angles.

Removing Pit-Stored Food. It's hard to get food from a pit in a frozen, snow-covered garden. Once a pit is opened, its entire contents should be removed. The vegetables that were in the pit will now keep only 1 or 2 more weeks. Though they look the same, pit-stored vegetables won't keep as long as freshly harvested ones. So you'll need to eat them up or shift them to another method of preservation. For this reason, it's better to construct several small pits rather than one large one. Put a small quantity of different vegetables in each pit. Then you can open only one small pit and get a variety of vegetables. When several kinds of vegetables are stored in the same pit, separate them with straw or leaves.

Root Cellars: Outdoor storage cellars may be attached to your house or located in your yard or under an outbuilding. But they should be convenient to your kitchen. Outdoor storage cellars can be constructed entirely or partly underground. Cellars constructed below ground stay at the best temperature longer and more uniformly than cellars that are above ground. The secret to a good root cellar is the combination of insulation where it contacts the air and a design that allows it to absorb warmth from the ground. That's why the more earth there is around your root cellar, the better it functions.

Water. It's important to dig a root cellar and not a well. Find out your water table level. Avoid a site that gets a lot of runoff from rain or spring thaws. Make the floor plan slope just a bit downward for drainage. If you have a water problem, ditch with drainage tile or gravel under it. Or if you end up with water 2 feet deep, make your floor out of planks over supports. You'll have plenty of humidity.

Outer Room. Some folks have an anteroom built outside the entrance to their cellar. That helps with insulation and provides a great place to store garden tools, empty canning jars, etc.

NOTE: Don't build using pressure-treated wood. The phenols used to treat it are dangerous poisons that will tend to vaporize into the air in your cellar.

Roof. Cover your roof with a waterproof material, and then put the dirt over that.

Underground Cellar. The walls and roof of an underground cellar must be strong to support the weight of earth over the roof. Stone and masonry block in combination with concrete can be used, but a cellar made of reinforced concrete is better. A typical underground cellar design has the whole structure, except the door, covered with soil. Wire screen over the outside ends of air intakes and ventilators keeps out birds and small animals. This kind of cellar can also serve as a storm cellar (or fallout shelter).

Partly Underground Cellar. This type of cellar is used in colder parts of the country. First you look for a small hill that you can dig into—or plan to haul dirt. This cellar has walls of masonry that are partly underground. Soil is banked around three walls, and one wall is left exposed. The exposed side has an insulated double door. If you have more than one storage compartment, an air inlet and a ventilator are needed for each one.

Bill Rogers lives in Wheatland, WY, one of the coldest places in the United States. He wrote me, "Your description of the double house, insulated, is great, but let's come back to the real ranch and mountain vegetable cellar. Most of us in the mountains have caves. We dig them in the mountainsides and it is extremely laborious, although not so laborious as you might think, going into rocky mountainsides—usually not blasting. Often your caves amount to no more than a slice into the hillside, walled up and roofed over. My own is inadequately insulated, but it became much more usable and dependable when I built a toolshed in front of the door—keeping it always sheltered and shaded. It never freezes, so I am inclined to believe I could not better my cave if I did insulate expensively."

More Types. Bill wrote me, "Some people in more level country shore up a huge mound of earth covering a specially constructed storehouse. An entranceway with a dead air space 3–4 inches thick between the inner and outer doors is really necessary in the way of insulating. This type of construction is necessary where the water table is relatively high throughout the year. Some people excavate a cellar and have done so since the days of the first pioneers. Two doors are necessary—one on the surface and one at the bottom of the steps. Ventilators are necessary for all types of vegetable cellars. Much more care is necessary in vegetable storing than most people realize. I lost my potatoes last winter due to the lack of air circulation through them. Cabbages keep fresh in bushel baskets, however! One of our garden problems is that in our short growing season everything ripens with a rush and you cannot use it—unless you can put the surplus in storage. Frost comes and everything will be lost unless you can move wheelbarrow loads into storage."

Mostly Above-Ground Cellars. Storing vegetables and fruits in outbuildings is practical only where the climate is consistently cold but the average temperature is not below freezing. Even in these climates, temperatures may drop to 0°F or below, and supplemental heat may be needed on very cold nights to keep your food from freezing. Thermodynamically controlled heat can be used if the building is wired for electricity. Only a small amount of heat is necessary to prevent below-freezing temperatures in a building unless the cold outside is extraordinary. But you'll have to watch the storage temperature closely whenever low temperatures are predicted.

Storage outbuildings can be made of masonry or lumber, but they must be well insulated. Hollow-block walls, regardless of thickness, don't insulate much. Put vermiculite or some other dry granular material in the channels of hollow blocks as each layer of block is laid. If you use cinder blocks, scrub them on both sides with cement grout to make them less porous. Then paint them on the inside with aluminum paint; the paint serves as a moisture barrier. Lay tar paper between the ceiling and joists as a moisture barrier, and spread at least 12 inches of dry sawdust or other granular material in the attic above the ceiling.

A frame building can be built of 2 × 4-inch studding and rafters. Make walls tight by sheathing the inside and outside of the frame with matched lumber. Insulate the space between the walls with loose fill or mineral wool blanket. Put laminated Kraft paper (with asphalt between layers), aluminum foil, or polyethylene between the
insulation and inside walls as a moisture barrier. Put building paper over the outside sheathing before you lay shingles or siding to make the building tight. Paint the inside of the building with aluminum paint or whitewash. To ventilate above-ground storage buildings, you need intake and exhaust vents.

**Imogene’s Cellar Design.** Here are her directions for building one like hers. The floor should be dirt, because root vegetables keep much better on a natural ground floor than they do on boards or concrete. The floor should be dug down at least a foot below natural ground level (more is better) so that you actually step down into your root cellar. This puts it below the level to which the ground generally freezes in winter.

Build your storage cellar as large or small as you like. It could be as small as 6 x 6 feet inside, but larger is nicer, especially if you have a large family. It will be mighty full in the fall and have lots of room in the spring. The walls are usually double and wooden and best set on a concrete footing. Build the concrete footing to go down a couple feet on the very outside to prevent rodents digging under. There are no windows, but the roof has summer air vents with a wire covering to keep out rodents. There should be at least two of these ceiling vents. They should be square, about 12 x 12 inches. After the freezing weather comes, stuff them up. Most people keep their canned goods in the root cellar too, so they cover the wall space from floor to ceiling with wooden shelves for holding jars. The vegetables sit on the floor.

There is a space of 2 feet between the inner and outer walls all the way around, which is filled with a good insulation like wood chips or sawdust (free around here, since we are a land of sawmills). There can be a layer of plastic between the wood and insulation. If the outside boards are done tongue and groove, that makes it even better insulated. In your construction, it’s also important to make the outer and inner walls as independent of each other as possible, because any connection between them will draw frost into your root cellar at that place. You have to connect them around the door, but you don’t have to anywhere else, so don’t. What you are building is a house inside a house, with insulation between the walls. The roof consists of a flat layer of boards (the inside house), 3 feet more of insulation, and then a gently sloped roof above that (the outside house) with a considerable overhanging eave. (That makes possible a good depth of insulation across the entire inside area of the cellar, except where your air vents go through in summer. They reach up through the insulation to the free air above.) The roof does not need to shed snow; snow is itself a good insulation. The door area should also be insulated by making two doors, one for the outside wall and one for the inside. You can add hanging blankets inside the door area for additional insulation.

**Maintaining Your Storage**

**KEEP THE STORAGE SPACE CLEAN:** Keep storage facilities for vegetables and fruits clean. Get rid of vegetables and fruits that show signs of decay. At least once a year, remove all containers from your storeroom. Then clean them and air them in the sun. Wash the walls and ceiling before you put back the containers.

**HARVEST FOR LIVE STORAGE:** Harvest during dry weather, not too soon after a rain, and let the surface of the product dry, since wet produce is much more susceptible to disease in storage. Handle food carefully to prevent skin cuts and bruises, which also invite decay. Containers should have smooth inner surfaces. Protruding wire staples in baskets and hampers, for example, damage food. Vegetables or fruits with skin breaks should go directly to the kitchen or another preservation system. Make sure there are no crushed, cut, or decaying foods mixed in with those to be stored. They’ll cause their neighbors to soon decay also. Harvest in early morning, or let crops picked in daytime heat cool outdoors overnight before you store them. Don’t wash produce before storing. Just leave the garden dirt on; it helps them keep. Some commercial foods are waxed to reduce moisture loss and appeal to potential buyers. Home folks don’t do that and have better food because of it.

**Containers.** Sturdy food-quality plastic cans with or without handles and with airtight lids are useful for holding grains, beans, flour, honey; making sausage; hauling produce and milk; and curing pickles and sauerkraut. You can reuse any plastic container from store-bought food. But don’t make the mistake of putting food in regular plastic garbage cans or bags, because they may be made out of a
kind of plastic that is very carcinogenic! It's safe to use a big enamel or stainless-steel kettle (enamel is cheaper, but it doesn't last as long because the enamel will chip). Crock with vegetables and fruits, nor is it so with dried, salted, sugared, spiced, or alchooled foods. These items require upkeep—regular, faithful attention all the while you have them. Humidity of 95 percent is almost rainfall and is difficult to achieve indoors. Humidity of 90–95 percent is very moist and good for storage of potatoes and other root crops. Too much humidity encourages mold and other decay critters. (Excessive humidity is present when water droplets form on the surface of the food.) A humidity of 60–75 percent is dry and good for storage of pumpkins and winter squash.

Testing for Dampness. But pumpkins, squash, and onions need a very dry but not cold place for their best storage. So they don't belong in your basement or root cellar at all if it's damp. To find out if your basement is damp, test for condensation by placing a small mirror against the wall. Should droplets or fog appear on the mirror after a few hours, it means that condensation is the cause of dampness. Ventilation fans might help but aren't worth it. Store those particular foods upstairs.

You can install a humidity gauge in your cellar. Delta Track sells a "Hygro Thermometer," which is about the size of a deck of cards, battery operated, with a digital display of temp and humidity and recording of daily min./max. of each: 800-962-6776; PO Box 398, Pleasanton, CA 94566. Or do this simple test for condensation in your basement. Spectrum Technologies sells humidity monitors: 800-248-8873; 23839 W. Andrews Rd., Plainfield, IL 60544.

Regularly Check the Stored Food
This old-fashioned way of food preserving is going to require a real adjustment in your attitude if you're used to thinking of preserved foods as a near absolute—putting the cans or jars on the shelf and the packages in the freezer, and forgetting about them until needed. It isn't so with storage of fresh vegetables and fruits, nor is it so with dried, salted, sugared, spiced, or alchooled foods. These items require upkeep—regular, faithful attention all the while you have them.

Root Cellar Checklist

1. Tour your root cellar at least once a week, carefully looking for problems. You'll be in a race with decay all winter long, just as you were in a race to preserve nature's abundance from your garden and orchard all summer long.
2. Be ready to make a switch from this method of preserving to another if it looks like you're going to lose some food. That means if there's a problem, you salvage what is possible and can, dry, pickle, freeze, or quickly eat it. You also want to remove any and all spoiling vegetables or fruits because the rot spreads to others if you let it go.
3. Green tomatoes and apples: If they have begun to spoil, check them every day or two. Remove bad apples and tomatoes. Take tomatoes that have turned red for kitchen use. If the apples start going in quantity, make a lot of pies or applesauce or freeze apple slices in syrup for pies.
4. Check crock pickles for excessive scum (or mold) on top. If they have it, pour off the brine, boil it, add another cup of vinegar and an extra handful of salt, and then pour it back onto the pickles.
5. Check dried fruits and vegetables for signs of mold. If you have mold, heat in your oven and then repackaged.
6. Check grains and grain products for insect infestation. (See Chapter 3.)
7. Check for mold or bugs in your home-dried fruits. If bugs are present, put the food in a small cheesecloth
bag and dip into boiling water for 6 seconds. Dry again and then store in something bug-proof. Or freeze for a few days.

7. Jams and jellies may develop surface mold. If one does, throw it out.

8. If a squash or pumpkin has developed a soft spot, cut out that spot and give to the animals. Cook up the rest to use, can, or freeze.

If you are interested in storing large quantities of food for a very long time (like years), make some Mormon friends. They have made a complete study of this and have lots of practice too. I am blessed with a Mormon mother-in-law who is a dear and precious mother to me and has guided me to a lot of learning. They'd rather be called "Latter-Day Saints," but you probably already knew that.

I think the biggest single principle of cellar-type storage is that you should put away more than you expect to need in order to allow for losses during storage. The thing that makes root-cellar storage really pay off is owning a pig or chickens, so you can recycle the food that doesn't keep into bacon and eggs. By late March, seven-eighths of your winter squash either will have been brought up to the kitchen for cooking or will have spoiled or be near enough spoiled so that you have fed it to the animals. In other words, if you let all your squash set on the shelves all winter long in whatever condition it was (and that would hasten spoilage of the remainder), only seven-eighths of it or less will make it to March. If you do end up with good food left over, you can share it with your neighbors (or the animals).

When you have made your major weekly inspection, sorting out what's bad and should be fed to the pigs and chickens (which is good for them) and setting aside what needs to be cooked up next week for the family, then stop a moment. Admire your shelves covered with home-canned food, your deep freeze full of vegetables and meat, the boxes of apples in the garage, the crocks of pickles and boxes of root vegetables covering your cellar floor, and the cabbage waiting in trenches outside in the garden. Feel good about what your family accomplished and secure about the future, and give thanks to your Good Lord for it.

**SUGARING—AND FRUIT PRESERVATION**

Sugar, salt, and alcohol were the original "chemical" preservatives. At sugar concentrations of 50–60 percent, sugar's preserving action begins to work. Above 70 percent, nothing grows. Because 15 percent salt and 70 percent sugar don't appeal to human taste, in the old days the former brine and the latter syrup were diluted before use. Pickles were removed from the brine for a day and soaked in several changes of clear water. Syrups were diluted with water to taste.

My favorite food "preserved in sugar" is pure honey, which will keep literally forever. You can make any jam into a self-preserving recipe by altering the amount of sugar used to the required 70 percent. But it's healthier to dry fruit, make fruit leather, or can fruit for a winter sweet, because those are naturally sweet without adding the empty calories of sugar.

In colonial America, dried pumpkin, maple sugar, and honey were used as sweetening agents. My mother bought plain old white sugar in 25- or 50-lb. bags and then transferred it to a bin in the kitchen. There was a bin for flour, too. They didn't go to town too often from the ranch. It was a long day's proposition, so when they did, the car really came home loaded. The sugar lasted a long time. Mama didn't often make desserts, though when she did they were delicious. Fudge and divinity at Christmas time was her candy repertoire. Oven-baked custard, apple pie, or oatmeal cookies were her everyday desserts.

I've got a real sweet tooth, and I practically ruined my teeth with candy bars and pop once I got away from Mama. Now I'm a mother too and fighting the same battle. I prefer using honey, and I can make a 5-gal. can last all winter.

There are four kinds of sugar. Fructose is found in fruits and honey. Glucose is also found in fruits and in the blood; it's the sugar they give in hospitals. Lactose is a kind of sugar found in milk; the whey from cheese making is rich in it and will sweeten your bread. If you boil down the whey, you get a more concentrated lactose syrup. Sucrose comes from sugar cane and sugar beets.

Fruit is a wonderful natural sugar. In summer when the fruit starts, the children and I quit cooking breakfasts. We just get up in the morning and head for the orchard. Who needs any other start to the day when there are trees loaded with heavenly ripe cherries waiting to be eaten? It's fun to gather 'round the tree, big ones hanging down fruit to the smaller ones, Mother pulling down low-hanging branches for smaller children to hang onto and strip. That's the easy part. Then we've got to put up the winter's supply.

**SUGAR ALTERNATIVES**

**Honey.** Some people substitute honey for sugar in food preservation recipes. This doesn't reduce the sugar content of preserved foods because 2 types of sugar—fructose and glucose—are the major components of honey. Honey can be substituted for sugar in canned and frozen fruits. The flavor of honey is sweeter than that of granulated sugar, so it is advisable to use less honey than the amount of sugar specified in the recipe. In jelly recipes without added pectin, honey can replace up to one-half of the granulated sugar. With added pectin, honey can replace up to one-fourth of the sugar. Be sure to use light, mild-flavored honey if you don't want noticeable flavor changes in your preserved food.

**Corn Syrup.** Light corn syrup can replace up to half the amount of sugar in syrups for canned fruits. Be sure to use light corn syrup. Dark corn syrup, sorghum, and molasses are a problem to use because their flavor overpowers the fruit flavor and may darken the fruit. On the other hand, if that's what you have, it won't win a county-fair prize, but it's good food.

**Artificial Sweeteners.** This stuff isn't good for you, but diabetics and desperate dieters may resort to it sometimes. You'll generally get better flavor if you can or freeze without any sweetener than if you use saccharin or aspartame (Nutrasweet or Equal). Saccharin may become slightly bitter when heated or frozen. Aspartame should not be used in canning because it breaks down when heated, but it can be added to food to be frozen. The best way is to add either of these just before eating the preserved food. If you do add them, it is better to undersweeten the fruit than to overdo it.

**Fruit Juice and Juice Products**

The quickest and easiest way I know to keep working men and women happy in hot weather is to keep gallon jars of
cool liquid in the refrigerator and a plastic gallon jar of ice cubes in the freezer compartment. I make lots of tea (wild strawberry leaf is Mike’s favorite, and wild mint is mine). I sweeten the tea with honey, chill it, and serve it plain or with ice cubes for a special treat. I also keep some of our spring water chilled in the refrigerator in summer for drinks. And the children enjoy the juices canned up from the previous summer’s fruit crop, thinned with cold water.

Way back when this book was first getting made, I had hopes of finding a young woman to come and work with me in return for room and board. I advertised. The first answer was somebody’s sister, whose sister I think was more enthused than she was. She called me up long-distance from Michigan, and when I told her we worked about a 12-hour day in the summer, she decided she wasn’t interested. Then an Oregon woman drove all the way here to look us over. She stayed an hour, declared, “Your place is just like my mother-in-law’s,” and left. By the next summer I was enthused more than she was. She called me up long-distance from her sister’s sister’s sister, whose sister’s sister was more interested. She stayed an hour, declared, “Your place is just like my mother-in-law’s,” and left. By the next summer I was getting some real solid inquiries, but by then Mike and I had decided not to take on any extras. But it’s really not so bad around here in the summer—12-hour days and all. Part of what makes it tolerable is having good things to drink.

Juice Extractor and Bottling Equipment: You don’t need special equipment to make fruit juices. Cider, grape juice and other juices in quantity are fairly easily extracted with the aid of a fruit press or a Meh-Maja, which is the brand name of a very fine Finnish steam process juice extractor. Or you can buy a juicer. A juicer or fruit press makes juice without cooking the fruit. The Juicing Book, steamers, a press for juicing citrus fruits without heating, a juice extractor for other fruits and veggies, a food strainer/sauce maker, etc., are available from Back to Basics: 801-571-7349. You make juice in the steamer, simmer for 40 to 70 minutes (still in the steamer), and then empty the hot juice directly into soda pop or wine bottles, or half-gallon or gallon cider jugs.

Jelly-Bag Juice Extraction: Cook the fruit (some berries can simply be mashed) and put it through anything from a cloth to a colander (good for liquids like tomato juice with some seeds). A modern one can be a fine-mesh nylon bag suspended somewhere for juice to drip through. Prop the bag/sieve up in a pan and go do something else while it drops, or use a rotary colander and rub the pulp around with your wooden pestle. If you are using a cloth, make it a sturdy one. You can “wring” out the juice, or pin the cloth to the sides of the colander with clothespins and let it drop. A first treatment often yields juice with pulp floating in it. If you want clear juice for jelly making or a beverage, give the juice a second straining through a clean cloth, or let it set overnight and pour off the top. You can often get extra juice from berries by taking the pulp of your first squeezing and putting it back on the stove with some water. Boil 5 minutes and then squeeze again.

Crushing Fruit. When directions call for crushing the fruit, you can use a wire potato masher, pastry fork, or slotted spoon for soft fruits. Firm fruits can be crushed with a food chopper. A colander, food press, or strainer will give you a puree. Don’t use galvanized ware in direct contact with fruit or fruit juices because the acid in fruit forms poisonous salts with the zinc. Metallic off-flavors may result from the use of iron utensils, chipped enamelware, or tinware that is not well-tinned.

Nectars: Juices like apricot, berry, melon, peach, pear, and plum are categorized as the ones that make “nectars.” They are best thinned with water or added to other juices.

Mixed Juices: Home-grown fruits vary widely in sweetness and flavor. Fully ripe fruits are best for making fruit juices. Use your judgment as to the thinning and sweetening desirable for your own juice. Berries, sweet cherries, apples, melons, pineapples, peaches, and apricots have relatively sweet juice. Cranberries, plums, currants, rhubarb, sour cherries and tart grapes have tart juice. The tart juices can be drunk sweetened and make fine additions to other juices or ginger ale. The amount needed to dilute sour cherry, plum, grape, and berry juices is generally one-third to one-half; you can use water or a bland juice or ginger ale to dilute. The “citrus” juices are orange, lemon, lime, and grapefruit. These are generally thinned with water and sweetened, and are often combined with other juices.

Preserving Juices
Your juices, once extracted, can be easily canned (waterbath time is 5 or 10 minutes), frozen, drunk on the spot, or made into syrup or frozen concentrate to be diluted later.

Freezing Juice: Freezing liquids isn’t hard. Put a plastic baggie into a pint or quart jar or tin can you’ve saved. Pour in the fluid and fold the baggie over the top of the fluid. The air space at the bottom of the baggie protects jars from breaking. If it is a widemouthed jar or if you don’t fill it near the neck, you can freeze liquids in glass without a baggie. When the juice is thawed out again, it will probably be more diluted near the top and oversweet near the bottom. Just stir it up.

Although you can freeze juice in almost anything, you’ll have a better-tasting long-term product if you manage to make it something you can seal. If you freeze in a canning jar, leave plenty of headspace:
Widemouthed pint jar  ½ inch headspace
Narrow-mouthed pint jar  ¼ inch headspace
Widemouthed quart jar  1 inch headspace
Narrow-mouthed quart jar  1½ inches headspace

Homemade Frozen Juice Concentrate. Many recipes assume you have frozen fruit juice concentrates, since there are so many fun things you can do with them. To make a homemade frozen juice concentrate just like the store-bought kind, you need only a large, narrow-necked container, such as a gallon jug, and a freezer.

Pour your juice into the container. Food-grade plastic works well. If you aren’t using plastic, be sure to fill no more than three-fourths full so you won’t risk breaking the jug when the liquid expands in freezing. Cap and freeze. After it is all frozen, remove the cap and turn the jug upside down. Suspend it by the “shoulders” over a lower container, such as a widemouthed gallon jar, so the drips won’t make a mess and because the drips are the good part. Don’t try to rush the draining process with heat. That would mess up the process because the ice melts, runs down, and dilutes the juice concentrate.

The reason it works is because the juicier bits melt before the plain water crystals do. When the drips running off are no longer sweet and colored, take away the jug. Finish melting the ice. Throw out the ice water. Now repeat your freezing and dripping procedure 2 more times (3 total). You now have a fine concentrate. Store it in the freezer.

CANNING JUICE: Heat high-acid fruit juices—from apricots, berries, red cherries, red grapes, peaches, plums, and rhubarb—to 190°F to inactivate enzymes and deepen color. If you do it in the top of a double boiler, you'll get a fresher fruit flavor. Don’t let the temperature reach the boiling point. Once it has reached 190°F, cool it quickly to keep the fresh flavor. If you have a choice, don’t heat apple, light-colored cherry, light grape, or citrus juices. Heat destroys vitamin C. Store in freshly sterilized bottles. Cap with cork-lined metal caps and turn upside down for 5 minutes. Leave bottles in a dark place. If you haven’t one, put the jars in paper bags or cardboard cartons. To hold flavor, color, and vitamins, have a storage place that doesn’t get above 70°F.

Old-Time Sealing Wax for Bottle Corking. Use 1 lb. resin, 2 oz. beeswax, and 1½ oz. tallow. Warm and combine. First cover cork using a brush, and push it into the bottle. Then dip the entire corked end of the bottle into the melted wax.

Summer Ices, Frozen Fruits
An “ice” is a frozen beverage. A “frappe” is a dessert ice that is basically a fruit sauce frozen only to a coarse mushy stage. A “sherbet” can be a water ice with a little dissolved gelatin or beaten egg white added. (For milk-based sherbets, see Chapter 10.) And then there are popsicles. Actually, you can use any popsicle recipe to make a frappe and vice versa. To make a frappe, just eat it out of a bowl before it is frozen clear solid. If you get a dessert ice frozen too hard to serve, let it thaw again until it has the consistency of thick mush. Then serve. Feel free to change the sweetening type and amount to suit your preference. You don’t have to have a crank freezer for any of these, although if you do, then by all means use it.

An electric ice shaver turns ice cubes into soft, fluffy snow. You can pour flavoring over it to make snow cones, slushes, etc. Shavers are available from Back to Basics for $29.95 (801-571-7349). They also sell lime, raspberry, grape, kiwi, etc., flavor concentrates (powdered—add water and sweetener, or liquid), dispenser bottles, ice molds, and recipe booklet.

Homemade Popsicles: These are cheap, easy, and even more fun for the children than going to the store. Children like strong, sweet juices like grape and cranberry for popsicles—but when kids are hot, anything will do. My little ones enjoy goat’s milk popsicles. Popsicle making is a nice way to use leftover juices from canned fruit, too.

Of Handles and Molds. You can use wooden sticks for handles and sturdy small bowls or cans for containers—work up a collection. Or buy popsicle molds; Tupperware and Back to Basics carry them. If you have a big family or lots of small friends, I recommend getting at least 2 molds so you can have one freezing while they are consuming the other. You can even make parfait popsicles by freezing a layer of one color and then a layer of another color. My plastic holders soon got lost or fell apart, but then we substituted sticks in a bowl or can and were fine. Fill the molds not quite full, insert your holder, and freeze.

Unmolding. Don’t let the gremlins pull the holders until you’re sure the center of the popsicle is solidly frozen and you have loosened the sides by running hot water over the back of the mold. Otherwise they might pull out the holder prematurely, leaving a hole that it won’t freeze back into. You don’t have to unmold all the popsicles at once. Just loosen as many as you need. Refill the emptied units and return to the freezer.
Jams and Jellies

Jams and jellies preserve easily because the sugar itself acts as a preservative. Jam is fruit boiled thick with sugar. Most jam recipes call for a 2:1 ratio of sugar to fruit by weight or volume. Some jam recipes that are really trying to hold down the sugar content call for a 1:1 ratio. Jelly generally has a 1:1 ratio, 1 c. juice to 1 c. sugar. Jelly making depends on having proper amounts of fruits, pectin, acid, and sugar. Jellying is a chemical change based on the presence of pectin and acid.

**Jam/Jelly Recipes:** Canning books always have jam and jelly recipes. You can get free ones with any package of commercial pectin that you buy or from your extension agent, and you'll find lots here and there in this book. You can personalize recipes with your own flavors and spices, but stay close to the recipe for the essential pectin/sugar/acid proportions.

**Pectin:** Pectin is the key to jelly. It's a natural substance in some fruits, especially underripe ones, that "jells" when heated and combined with acid from the fruit and sugar. Apples are usually rich in pectin. Natural ripening causes the pectin to break down. So if your fruit is overripe, your jelly will never get firm no matter how long you boil it. Peaches, strawberries, and cherries don't have much pectin. You can combine pectin-rich fruits with pectin-poor fruits, use commercially prepared pectin, or make your own.

**No-Sugar Pectin.** Pomona Universal Pectin sells low-methoxyl pectin. That's a pectin which jells fruit without using sugar in the recipe. In this way, jams, jellies, and fruit spreads can be made without sugar or long boiling times: 413-772-6816; PO Box 1083, Greenfield, MA 01302; aggie.horticulture.tamu.edu/plantanswers/recipes/sugarless.htm. For more ideas, see Canning and Preserving without Sugar by Norma M. MacRae. Her recipes for canned fruits and jams use honey, frozen juice concentrate, canned juice, date sugar, and dried fruits for sweetening. But keep in mind that every time you reduce the sugar, you're reducing the time the jam or jelly can be safely kept out of the freezer before mold grows on it.

**Homemade Pectin From Apples.** To make this, use skins and cores of cut-up apples or whole apples, or apple pulp. Boil 2 lb. apples with 4 c. water for about 45 minutes. Extract the juice through a cloth or jelly bag without using pressure. Boil the resulting juice 15 minutes and can it if you won't be using it right away. Use a cup of this apple pectin per 1 c. pectin-weak fruit juice. When making jellies using this combination of apple pectin juice and other fruit juice, ¼ c. sugar per 1 c. liquid is usually correct.

**Old-Time Test for Pectin.** Here's a way to tell whether you have enough pectin present for good jellying: Into a glass container put 1 T. juice; with this mix 1 T. alcohol. If you have enough pectin, the fruit juice will turn into a jelly-like mass that you can gather up with a spoon. If not enough pectin is present, it won't jell when you add the alcohol, and that tells you to add some more pectin.

**Modern Test (Jelmeter).** Or you can buy a modern pectin tester from Lehman's, Box 41, Kidron, OH 44636, and have perfect jelly every time. It's called a Jelmeter. In 60 seconds it tells exactly how much sugar must be added to your juice and whether or not pectin is needed. Comes with instructions and 50 recipes.

**Short of Pectin?** Add sour apples, crab apples, currants, lemons, cranberries, sour plums, loganberries, or green gooseberries. Ripe apples, blackberries, oranges, grapefruit, sour cherries, and grapes have a sort of average pectin content. Fruits that don't jell well on their own because of low pectin content are apricots, peaches, pears, strawberries, and raspberries.

**Altitude Affects Jelly Making:** Martha Mohan, who lives over 6,000 feet up near Hotchkiss, CO, wrote me, "To make jelly from wild berries at altitudes over 6,000 feet, I have found that the wild berries should be boiled at least 3 times and preferably 4 times as long. At 6,500 feet I cook all jellies 3 times as long as cooking charts show, until it sheets off the spoon. An old-timer, a lady we know, who lives at 8,300 feet elevation, told me this and it works for me. These jellies are really worth the extra effort and are great with any wild meat."

**Acid Content:** You must have enough acid content to jell. Taste the juice for tartness. If it isn't very tart, add lemon juice for extra acid.

**Jelly Making, Old-Time Directions:** To make jelly, the fruit has to be cooked; cooking brings out the pectin in the right form for jelly making. Only with
commercial pectin can you jell uncooked fruit. To jell with
natural pectin, the fruit is generally cleaned, cooked, mashed,
and put through a jelly bag or two to get the juice
that is the jelly base. If you squeeze the bag you will get
pulp too, which is okay unless you want a clear jelly—in
that case, don’t squeeze the bag.

**JELLY MAKING WITHOUT ADDED PECTIN:** These are
USDA instructions. Use only firm fruits naturally high in
pectin. Select a mixture of about ⅓ ripe and ⅔ underripe
fruit. One pound of fruit should yield at least 1 c. clear
juice. Do not use commercially canned or frozen fruit juices
because their pectin content is too low. Using peels and
cores adds pectin to the juice during cooking of the fruit
and increases jelly firmness.

Wash all fruits thoroughly before cooking. Cut firm,
larger fruits into small pieces. Crush soft fruits or berries.
Add water to fruits as needed. Put fruit and water into a
large saucepan and bring to a boil. Simmer, stirring occasion­
ally, for the amount of time listed or until the fruit is soft.

When fruit is tender, press lightly through a colander.
Then let juice drip through a double layer of cheesecloth or
a jelly bag. Excessive pressing or squeezing of cooked fruit
will cause cloudy jelly.

Using no more than 6 to 8 c. extracted fruit juice at a
time, measure and combine the proper quantities of juice,
sugar, and lemon juice and heat to boiling. Stir until the
sugar is dissolved. Boil over high heat, stirring frequently,
until the jelling point is reached. Here are some recipes:

**APPLE JELLY** Add 1 c. water per 1 lb. fruit. Simmer 20
to 25 minutes before extracting juice. To each 1 c. strained
juice add ⅔ c. sugar. Optional: add ⅔ t. lemon juice. If you
start with 4 c. juice, your jelly yield will be 4 to 5 half pints.

**BLACKBERRY JELLY** Add 0–⅓ c. water per 1 lb. fruit.
Simmer 5 to 10 minutes before extracting juice. To each 1 c.
strained juice, add ⅔ t. 1 c. sugar. From 4 c. juice, your jelly
yield will be 7 to 8 half pints.

**CRAB-APPLE JELLY** Add 1 c. water per 1 lb. fruit.
Simmer 20 to 25 minutes before extracting juice. To each 1 c.
strained juice, add 1 c. sugar. Jelly yield from 4 c. juice will be
4 to 5 half pints.

**GRAPE JELLY** Add 0–⅓ c. water per 1 lb. fruit.
Simmer 5 to 10 minutes before extracting juice. For each 1 c.
strained juice, add ⅔ to 1 c. sugar. Jelly yield from 4 c. juice
will be 8 to 9 half pints.

**PLUM JELLY** Add ⅓ c. water per 1 lb. fruit. Simmer 15
to 20 minutes before extracting juice. To each 1 c.
strained juice, add ⅔ c. sugar. Jelly yield from 4 c. juice will be
8 to 9 half pints.

**NO-SUGAR JELLY** To 1 c. fruit juice, take 1 to 2 T.
unflavored gelatin that has been dissolved in 1 to 2 T. cold water.
(Stir the gelatin into the cold water until well dissolved.
Let stand a few minutes.) Now add hot juice steadily and stir
well. Set aside to cool in your refrigerator. Because there is no
extra sugar in this kind of jelly, it won’t keep without refrigeration
and you must use it up within two weeks.

**HONEY-FRUIT JELLY** Combine 2 c. high- or medium-
pectin fruit juice, ⅓ c. mild-flavored honey, and 2 t. lemon
juice. Bring to a boil and stir in at once 2 T. powdered
pectin. Let boil 10 minutes and pour into your jelly glasses.

**FOR LOW-PECTIN FRUIT JUICES,** use 4 t. lemon juice and 3 T. pow­
dered pectin. If you want to use homemade pectin, substitute
2 c. homemade pectin for both the lemon juice and pow­
dered pectin.

**MICROWAVE JAMS AND JELLIES:** Use only recipes de­
volved specifically for the microwave (see your librarian).
And consider that recipes developed for one microwave
may not work in another because of differences in power
output between the ovens.

**TESTING JELLY DONENESS**

**Temperature Test.** Use a jelly or candy thermometer. Boil
to a temperature of 220°F at sea level, 218°F at 1,000 feet,
216°F at 2,000 feet, 214°F at 3,000 feet, 212°F at 4,000
feet, 211°F at 5,000 feet, 209°F at 6,000 feet, 207°F at 7000
feet, and 205°F at 8,000 feet of altitude.

**Sheet or Spoon Test.** To see if the jelly is ready for can­
nning, dip a cool metal spoon into the boiling jelly mixture.
Raise the spoon about 12 inches above the pan (out of the
steam). Turn the spoon so liquid runs off the side. The jelly
is done when the syrup forms 2 drops that flow together
and sheet or hang off the edge of the spoon.

If your jam or jelly doesn’t jell, here’s a tip. Thin jam or
ejelly is often caused by lack of pectin, or too much or too
little acid. The best way to fix it is add gelatin. Just pour the
non-jelled stuff back into the pan. Heat to boiling. Shake a
package of gelatin out over the top and then stir it in until
all dissolved. One envelope (1 T.) gelatin thickens 4 c.
runny jelly or jam. Pour it into jars. To can, put on
lids and process in boiling-water bath 10 minutes.

**WHEN JELLY IS DONE:** Remove it from the heat and
quickly skim off foam. Using a widemouthed funnel, ladle
the jelly into sterile jars, leaving ⅛ inch headspace. Adjust
lids and freeze or can.

**Freezing.** If you use commercial pectin you can freeze your
jams and jellies. Use plastic freezer containers. Good in­
structions for both canned and frozen jams and jellies come
with each package of Sure-Jell or Jam and Jelly Pectin.
Frozen uncooked jam keeps that delicious fresh fruit flavor
but will be softer than cooked jams.

**Canning.** Pour hot into sterile half-pint or pint canning jars,
leaving ⅛ inch headspace. To sterilize empty jars, put them
open side up on a rack in a boiling-water canner. Fill the
canner and jars with hot (not boiling) water to 1 inch above
top of jars. Boil jars 10 minutes. Remove and drain hot ster­
ilized jars one at a time and fill with food. Food residue
should be removed from each jar’s sealing edge with a clean,
damp paper towel. New 2-piece canning lids prepared ac­
cording to manufacturer’s directions should be put on.

After screw bands are tightened, process jars in a boil­
ing-water canner. Fill canner half-full with water and pre­
heat to 180°F. Load sealed jars into the canner rack and
lower with handles, or load one jar at a time with jar lifter onto rack in canner. Add water until you have a level of 1 inch above jars. Cover. When water is boiling vigorously, lower heat to maintain a gentle boil. Process all jellies and jams in half-pint or pint jars for 5 minutes if you live at 1–1,000 feet; for 10 minutes at 1,001–6,000 feet; or for 15 minutes above 6,000 feet. After the processing time is over, remove jars from the canner with a jar lifter and place on a towel or rack. Do not retighten screw bands. Air-cool jars 12 to 24 hours. Remove screw bands and check lid seals. Jelly and jam are best if consumed within a year.

NOTE: Here are a few jam/jelly precautions. Don’t put a jam or jelly into a quart jar; it won’t jell. Don’t double a recipe. Open-jellies—especially low-sugar ones—are more likely to mold. Jams. Apricot, blackberry, boysenberry, dewberry, currant, elderberry, grape, mayhaw, mint, peach, plum, black or red raspberry, loganberry, rhubarb, and strawberry.

**Jellies and Jams With Added Pectin:** Fresh fruits and juices, as well as some commercially canned or frozen fruit juices, may be used with commercially prepared powdered or liquid pectins. The order of combining ingredients depends on the type of pectin used. Complete directions for a variety of fruits are provided with packaged pectin. Jelly or jam made with added pectin requires less cooking, generally gives a larger yield, and has more natural fruit flavor. In addition, using added pectin eliminates the need to test for doneness. The following recipes are usually available with packaged pectins.

**Jellies.** Apple, crabapple, blackberry, boysenberry, dewberry, currant, elderberry, grape, mayhaw, mint, peach, plum, black or red raspberry, loganberry, rhubarb, and strawberry.

**Jams.** Apricot, blackberry, boysenberry, dewberry, loganberry, red raspberry, youngberry, blueberry, cherry, currant, fig, gooseberry, grape, orange marmalade, peach, pear, plum, rhubarb, strawberry, and spiced tomato.

**NOTE:** Buy new packaged pectin each year because old pectin may not jell well.

**Packaged-Pectin Recipes**

**Grape-Plum Pectin Jelly** You’ll need 3 1/2 lb. ripe plums, 3 lb. ripe Concord grapes, 1 c. water, 1/2 t. butter or margarine (optional ingredient to reduce foaming), 8 1/3 c. sugar, and 1 box (1 1/2 oz.) powdered pectin. Wash and pit plums. Do not peel. Thoroughly crush plums and grapes, one layer at a time, in a pan. Add water. Bring to a boil, cover, and simmer 10 minutes. Strain juice through a jelly bag or double layer of cheesecloth. Measure sugar and set aside. Combine 6 1/2 c. juice with butter and pectin in a large pan. Bring to a hard boil over heat, stirring constantly. Add the sugar and return to a full rolling boil. Boil hard for 1 minute, stirring constantly. Remove from heat, skim off foam, and quickly pour into sterile half-pint jars, leaving 1/4 inch headspace. Adjust lids and process. Yield will be about 10 half pints.

**Pear-Apple Pectin Jam** You’ll need 2 c. peeled and crushed fully ripe pears, 1 c. peeled and finely chopped apple, 1/4 t. ground cinnamon, 6 1/2 c. sugar, 1/2 c. bottled lemon juice, and 6 oz. liquid pectin. Wash, peel, and core pears. Crush well and measure 2 c. into a large pan. Wash, peel, core, and finely chop 1 c. apples. Add apple to pears and stir in cinnamon. Thoroughly mix sugar and lemon juice into fruits and bring to a boil over high heat, stirring constantly. Immediately stir in pectin. Bring to a full rolling boil; boil 1 minute, stirring constantly. Remove from heat, quickly skim off foam, and pour into sterile half-pint jars, leaving 1/4 inch headspace. Adjust lids and process the jars as above. Yield will be about 7 to 8 half pints.

**Strawberry-Rhubarb Pectin Jelly** You’ll need 1 1/2 lb. red stalks of rhubarb, 1/8 qt. ripe strawberries, 1/2 t. butter or margarine (optional to reduce foaming), 6 c. sugar, and 6 oz. liquid pectin. Wash and cut the rhubarb into 1-inch pieces and blend or grind. Wash, stem, and crush strawberries, one layer at a time, in a large saucepan and simmer 10 minutes. Strain juice with a jelly bag or double layer of cheesecloth. Combine and mix 3 1/2 c. juice and sugar. Add butter if desired. Bring to a boil over high heat, stirring constantly. Immediately stir in pectin. Bring to a full rolling boil; boil hard 1 minute, stirring constantly. Remove from heat and quickly skim off foam. Pour into sterile half-pint jars, leaving 1/4 inch headspace. Adjust lids and process. Yield will be about 7 to 8 half pints.
headspace. Adjust lids and process as above. Yield will be about 7 half pints.

**Syrups**

Homemade syrups can be beverage-based syrups or sweet pancake-type syrups meant to be used straight and poured over another food.

**BEVERAGE-BASED SYRUPS:** These are handy for making drinks on camping trips and at picnics. They keep well in the refrigerator, and a little syrup poured into a glass three-quarters full of cold water or soda water and ice makes an easy, quick drink the children can fix for themselves. Just about any fruit juice can be made into a syrup—cherry, raspberry, and the like. Add ice, if possible, when serving. Dilute with ginger ale or various clear bubblies for variety. You can store unsealed syrup in bottles or a fruit jar. Store in a cool, dark place.

**PLAIN SUGAR SYRUP ("SIMPLE SYRUP")** Boil 2 c. sugar with 2 c. water for 5 minutes. Chill and store in a covered jar. Or water-bath process this for 15 minutes, and then it can be stored on the shelf for the long term. This was popular with Great-Grandmother for sweetening summer drinks, because the sugar was already in solution and she didn’t have trouble with sugar settling in the bottom of the glass.

**STANDARD FRUIT SYRUP RECIPE MEANT TO BE SEALED** Wash currants, black or red raspberries, blueberries, grapes, elderberries, and so forth. Simmer in water to cover until soft. Drain juice and strain it. For every 2 c. juice, add 1 1/4 c. sugar. Boil 15 minutes. Skim and pour into sterilized bottles. Bottle hot and seal or cork, making sure the bottles are airtight. Tie plastic or foil over the top, wrap around the top with sticky tape, or tip the tops of the bottles into sealing wax. Because syrups may ferment after being open for 2 or 3 days, use small bottles.

**STRAWBERRY SYRUP** Take ripe strawberries, crush in a cloth, and press out the juice. For each 2 c. strawberry juice, add 2 c. Plain Sugar Syrup (recipe above). Boil gently for 1 1/2 minutes. Skim off the scum. Pour into sterile bottles and seal. Optional: Add some whisky to the syrup.

**PLUMB SYRUP** Cook 3 lb. plums and 3 lb. sugar with a little water for 20 minutes, stirring often. Drain without squeezing. Measure your syrup. For each 2 cups, add 1/2 t. almond flavoring. (Optional: Add whisky or brandy, from 1/2 t. up to 1 qt.) Use the leftover plum pulp to make a fruit pie or butter.

**LEMON SYRUP** Put 1 c. water and 1 qt. sugar into a pan. Simmer, stirring constantly, for 3 minutes. Skim if needed. Add 1 c. lemon juice and 1 T. grated lemon rind, and simmer another 2 minutes. Pour into sterile bottle and seal.

**PANCAKE SYRUPS:** Homemade syrup was one of the delights of my childhood. Usually it was chokecherry syrup poured over pancakes. Sometimes it was honey syrup, for we allowed bees on the place and the bee man repaid us in honey, more honey than we knew what to do with.

The first money I ever made was peddling buckets of chokecherries in our local metropolis—Livingston, Montana. I rode my pony, Shorty Bill, laden with empty buckets a couple of miles on up the mountain from our home to a little canyon where the chokecherry bushes were thick. I worked hard all day picking berries and filling those metal buckets. Rode home, tired but satisfied, with the fruit of my labors. The next day was Mama’s day to drive the 30 miles into town to do a few weeks’ shopping. She took me and my buckets of chokecherries. I went from door to door, knocking on doors, offering my chokecherries for sale. I think I charged about a dollar a bucket. Those housewives were really pleased to see buckets of chokecherries like the ones they had picked when they were little—something that wasn’t sold in stores.

The old-time syrups were used not only on hot breads like biscuits and pancakes and on ice cream but also on puddings and pound cakes, as flavorings in sauces and sherbets, and as beverage bases. One or two spoonfuls of a fruit syrup in a glass of cold water with shaved ice makes a nice summer beverage. Most of the recipes below call for white sugar, but you can substitute honey. The trouble with using honey is that it has such a distinctive flavor of its own that if you use it in everything, you get tired of honey’s flavor pretty soon.

**BASIC FRUIT SYRUP** Fruits vary in natural sweetness or tartness, chokecherries probably being at one extreme and dark sweet cherries probably the other. So the amount of sugar to add involves your judgment. But in general, get the juice from the strawberries, raspberries, currants, grapes, or what you want as directed for fruit juices. After the juice is brought to a boil, add sweetening and boil down to the density you want. Then can.

**WHOLE FRUIT SYRUP** Wash, core, and pit the fruit peel if you think the peels wouldn’t make it through the blender or wire-mesh strainer or wouldn’t be nice. Now blend or force through a wire strainer. For every 1 c. mashed fruit, add 1/4 c. water, 2 t. lemon juice, and 1/2 c. honey. Boil together 5 minutes, stirring constantly. Now take your syrup off the stove. Skim off the foam. Pour into hot jars and seal or cool for serving.

**QUICK BERRY SYRUP** If you haven’t time for all the boiling down, do this. For each 4 c. berry juice, stir in 2 c. sugar and 2 c. light corn syrup. If it is strawberry or raspberry juice,
add 2 T. lemon juice (the others don't need it). Boil. Skim if needed. To can it, process 10 minutes for pints or quarts.

**RESOURCESFUL WOMAN'S SYRUP** Take any leftover fruit syrup or juice. Sweeten as needed and boil down until it is syrup-like.

**PHONY MAPLE SYRUP** Boil 1 c. dark brown sugar with 1/2 c. water for 5 minutes. Add 1/4 t. maple flavoring and 2 T. butter. Serve warm.

**CREAM AND SUGAR SYRUP** Mix in a pan 1/2 c. cream, 1 c. brown sugar, and 1/2 c. dark corn syrup. Bring to a boil and serve warm.

**Fruit Sauces**

If you have a batch of fruit that is going bad, and you want to get it put up the quickest, easiest, cheapest way possible—sauce it! Applesauce isn't the only member of this family. You can sauce cherries, peaches, rhubarb, cranberries, etc. Berries make fine special sauces to go on desserts. Apricots and even prunes can be made into a sauce. The sauces aren't meant to be supersweet. Sweeten to taste. The right amount of sweetness depends on you—and on the fruit.

**BASIC SAUCE** Prepare your fruit (peel, core, or whatever is appropriate). Add it to boiling water (a third part or less of your fruit amount). Cover and simmer gently until tender. Remove from heat. Put the fruit through a strainer to make a smooth sauce, or use as is. Add sweetening and mix well. Always use a wooden spoon to stir and a really heavy (non-aluminum) pan to cook it in.

**BASIC FRESH, RAW-FRUIT SAUCE** Crush fruits such as peaches, raspberries or strawberries. Sweeten to taste and serve over ice cream, pudding, or cake.

**CANNING A HIGH-ACID SAUCE:** Follow Basic Sauce recipe (above). Return to a boil again. Have jars ready. Boil some lids in a pan of water. Using a widemouthed funnel, quickly pour the very hot sauce into the jar. Put on the first lid and then the screw one. Now give it 15 minutes of hard boiling in a water bath. Lift out, tighten, and set aside to cool.

**FREEZING A FRUIT PUREE OR SAUCE:** If needed, cook or steam your fruit in water until soft. Then mash or press through a colander or strainer, or blend. Add sweetening and/or lemon juice to taste. Heat to boiling; then cool as rapidly as possible. Pack into freezer containers. Leave headspace for expansion from freezing.

**Other Sauces**

Great-Grandmother was strong on sauces. She made her own and made lots of different kinds. Her "pudding" (really a steamed bread) was always served with a sauce. The calf's-foot jelly also usually had a sauce. I like coffee jelly with a simple brown-sugar-dissolved-in-rich-cream sauce. Sauces generally run in three types—sauces for fruit, meat, and puddings. My sauces for fruit generally are based on whipped cream. To go with meat at table, it's usually a homemade fruit ketchup for me. The other kind I make a lot is a barbecue sauce, which to me means some form of tomatoes, plus molasses, a dash of vinegar, and some chopped onion, which I mix together and pour over the meat when it's about one-third to one-half done. Barbecued meat is a favorite with the children. (Anything sweet is a favorite with the children.)

**FRUIT AND CREAM SAUCE** Whip 1 c. cream and sweeten with about 1/4 c. honey. Put the whipped cream on your pudding or shortcake and then pour a spoonful of fruit on top.

**Fruit Butters**

A "butter" is a thick, smooth sauce made by straining fruit or vegetables. You can use a butter just like a jam, to spread on pancakes or bread, but it doesn't have nearly as much sugar in it. Just cook up the food with enough sweetening to suit you, add any other seasoning you want, can it, and you're done. Personally I think the tarter fruits make better butters. Peach or sweet cherry butter turns out almost too sweet. But apple and apple cider butter made with a tart variety of apple is good, and apple-plum butter is our alltime family favorite (recipe under "Apple" in Chapter 6).

We first started making apple-plum butter at our first home in Juliaetta, 4 miles down the road from here. The nearest thing that place had to an orchard was a big walnut tree in the front yard—so when fruit season came, I scavenged up and down the highways and byways. This region is unusual in that everywhere, throughout the years, pioneers and others have stopped to lunch or picnic and have left apple cores and plum pits. The volunteer apple and plum trees generally have a smaller fruit, but they are loaded almost every year and free for the picking. So the children and I would drive down the road with a back seat full of cardboard boxes and then go home and make apple-plum butter, one-third plum to two-thirds apple.

**MAKING A BUTTER:** It basically takes long cooking over very mild stove-top heat. You have to watch it closely and stir very frequently. For fruits, cook in an enamel or stainless-steel pan and use a wooden spoon to stir. Cook on low heat slowly for a long time. If you are very busy, cook it in the oven instead, in a covered kettle at a temperature of 300-350°F Then you don't have to stir it, and it doesn't burn on the bottom. If your sauce doesn't get smooth enough to suit you, put it through a rotary colander after cooking. Season your finished butter with cinnamon, cloves, nutmeg, allspice, or whatever you like.
**Foley Mill or Rotary Colander:** This is a cone-shaped colander with a wooden mallet to help work the stuff through. You fill it with goop and then turn the wooden mallet, rolling it around the sides of the colander. Don't just stomp with the mallet—that gets you nowhere.

**Canning a Fruit Butter:** Have the butter boiling on the stove and proceed by my directions under "Canning" in this chapter. Use the times under "Applesauce" in Chapter 6. Be careful, because the thick sauce is hard to heat clear through.

**Freezing:** Just pour into a container, cool, and put in the freezer. Can or freeze butters in half pints or pints because a butter that isn't heavily sweetened will mold in a couple weeks, even if refrigerated, unless you can depend on your family to eat it up faster than that.

**Ketchups**
A "ketchup" is a fruit or vegetable pulped and preserved with some combination of salt, vinegar, spices, and sugar. Just which of those and how many can vary a lot. It can be APPLE KETCHUP:

A "ketchup" is a fruit or vegetable pulped and preserved with some combination of salt, vinegar, spices, and sugar. We tried to get her to the doctor yesterday, but it is the first morning. Dolly is playing the piano. She had a little sleigh-wooden mallet, rolling it around the sides of the colander.

**APPLE, PLUM, OR GRAPE KETCHUP:**

Start with 1 qt. applesauce. Or for grape sauce, cook grapes in an enamel kettle slowly until soft (about 25 minutes). Then put through colander to get the grape puree. Cook plums and colander them for plum sauce. Combine 1 qt. of any of those sauces with 1 t. ginger, 1 t. cinnamon, 1 t. cloves, 2 c. vinegar, 1 t. pepper, 1 t. mustard, 1 t. onion juice, and 2 t. salt. Simmer slowly until thick. Pack into pint jars. Adjust lids. Process in boiling-water canner 15 minutes. If you like sweet sauce, add brown sugar or molasses to taste.

**Apple Ketchup:**

**Apple Ketchup:**

**APPLE KETCHUP:**

Start with 1 qt. applesauce. Or for grape sauce, cook grapes in an enamel kettle slowly until soft (about 25 minutes). Then put through colander to get the grape puree. Cook plums and colander them for plum sauce. Combine 1 qt. of any of those sauces with 1 t. ginger, 1 t. cinnamon, 1 t. cloves, 2 c. vinegar, 1 t. pepper, 1 t. mustard, 2 t. cinnamon, 2 medium-sized onions chopped very fine, 1 T. salt, and 2 c. vinegar.

**For some reason I'm having a hard time concentrating this morning. Dolly is playing the piano. She had a little silihing accident day before yesterday and still isn't able to walk. We tried to get her to the doctor yesterday, but it is the first week in January, with unusually heavy snows. After struggling about an hour we gave up and decided to wait until today. I'll try again this afternoon. The pickup is all chained down to the highway. Worse still is trying to get home again up our mountainside. About a week ago Mike and I were driving in, and we literally started to slide off the cliff. It's a good 200 feet to the bottom. I chickened out first, opened the car door, and said, "Mike, I'm leaving." He lasted about 10 seconds more, and then left too. The car hung there until the next day. He got our crawler tractor (a Cat with tracks instead of wheels) going and recovered the vehicle.

In a way I enjoy the snow. It reminds me of winters when I was a little girl. On the sheep ranch in Montana, we were really on top of the world. The lowest point on the ranch was 6,000 feet. The buildings were located at that point. If I rode my horse on up to a high point, I could easily see 75 miles on a clear day, and days were mostly clear in summer. ("Oh, give me a home where the buffalo roam, and the deer and the antelope play, where seldom is heard a discouraging word and the skies are not cloudy all day")

So today I have all five of them home instead of the usual four. I'm trying to keep them usefully occupied. Danny and Dolly are working in arithmetic workbooks. Becca is working in a pre-primary reading workbook. Luke is in the basement playing with the pumpkins, and Sara is discovering she can crawl under chairs. When I was a little girl, I spent a lot of time studying at home with my parents—usually January and February. When I did go to school, I rode horseback the 2 miles each way.

It wasn't really a "one-room" school, for it had a cloak-room in front and a teagerage in the back. The teacher slept and cooked there when the snow got too deep for her to drive back and forth from the ranch where she lived with her husband, in the Shields River Valley below, between Clyde Park and Wilsall. Our creek, school, and community were all called Bracket Creek. That is home in my heart, though long gone in the world of reality. On cold days like today, Mrs. Carroll would fix us some hot canned soup on top of the potbelled wood stove that heated the classroom to complement the cold lunches we brought from home.

Everybody rode horseback to school. Some rode 5 miles each way. You can make fast time when you have a good horse and when you're used to it. There was a little barn behind the schoolhouse where the animals waited patiently for school to be out, and then the merry race to the crossroads began. I always lost. I rode a not-so-young half-Shetland gelding called Shorty Bill.

He was my closest friend. I would go out to the field to get that horse after breakfast—a little kid running with bri-dle in hand. He would run across the field to meet me.

We'd go down to the big red barn with its vast mow full of hay and its underparts full of a complicated wonderland of stalls, pens, grain, and harness rooms, where Shorty would have his breakfast of rolled oats, and I'd saddle him up.

On summer days, when the business at hand wasn't serious, I would often ride him with no saddle or bridle. I could pull myself up by a handful of his mane. (It got sparer and sparser at the point where I grabbed.) I'd push on his neck to show him the direction I wanted him to go, kick him to make him go, and slide to the side to tell him I wanted to stop. In summer there was hard work to do on horseback, though, and Shorty had no part of that. That was for the 5 big horses we had, the largest being a great big pink-eyed Appaloosa that could pick his way down a cliffsedge with 200 lb. of pack rattling on his back like there was nothing to it.

Once every week we had to take the Appaloosa and the other horses, all loaded with food and general supplies, up to the sheep camp to help move it. We'd take down the tent.
and sack up the pots and pans and sleeping bag and gun. Then the horses would carry it all to the new grazing site. The ride was generally miserable. Big biting horseflies drove everybody crazy, man and beast. They are the meanest fly in the world, I think, with a bite so hard it leaves a bloody mark. If they happen to get your horse in a tender place, you've suddenly got a very insecure seat.

Well, that ought to be enough digression to get my head organized. Digressions are easier and more fun to write than the rest of this.

**Spiced Fruit**

Spiced fruit doesn't have to be canned or frozen. The real old-time recipes don't spoil—they just get spicier and spicier. In small amounts they are very tasty—like the spiced crab apples that you can get in the store, only much more spicy. This is not a method of preserving a staple food, just a holiday goodie.

If your fruit does show signs of fermentation, pour off the liquid, boil it awhile, and then pour back over the fruit. Brandied fruit has an alcohol content, but spiced fruit doesn't. For a milder version, you can cut back on sugar, vinegar, and spices and then can the results. The real thing can be left in a bowl with a plate on top all winter. I've done it. Whenever you want some, just fork it out. Don't be bothered by floating mold or scum. Your fruit is below the level of the fluid's surface. Rinse the fruit before serving, in case any top glop came along as you fished it out (like when you make crock pickles).

**Basic Spiced Fruit:** Use 7 lb. fruit, 4 lb. sugar, 2 to 4 c. vinegar, and 1 T. each of cinnamon, cloves, and allspice. Pare peaches and pears. Prick plums and tomatoes with a needle in several places to help the preservatives get inside. Boil the fruit in the syrup 5 minutes. Remove fruit and boil the syrup until it has thickened some. Put the fruit in jars and pour the boiling syrup over it. You can spice blackberries, currants, gooseberries, peaches, pears, plums, tomatoes, cherries, crab apples, watermelon rind, pieces of almost-green cantaloupe, apricots, nectarines, prunes, quinces, citrus, and so on. Let your spiced fruit stand at least several weeks before using it.

**Honey Substitution:** My spiced fruit recipes all use sugar. But in the Middle East, fruit is preserved in a syrup made of honey and vinegar, and I'm sure you could convert any sugar recipe and do the same thing.

Becca (short for Rebecca) just crawled down from my lap to go hold a bunny. Santa brought her two little half-pounders for Christmas. They make great pets. Fearless now, they hop all over the place. Makes January a little livelier for the at-home folks. Luke, his silver pistol, and his little toy crawler tractor are now all in my lap (replacing Becca). And on we go to brandied fruit.

**Brandied Fruit**

Foods preserved in alcohol are "brandied." Wines and foods containing over 14 percent alcohol by volume are self-preserving. Wines and foods with a weaker concentration of alcohol can become sour and vinegary. Brandied food should be kept cool and airtight. Burying it deep in the ground works well. The trouble with preserving food by brandying is that it will give you a hangover. I'd hate to have to get drunk to eat.

Incidentally, many people hold very strong opinions for or against the use of alcohol. Some of my best friends wouldn't let the stuff in their homes in the form of tutti-frutti or anything else. I have sympathy with that point of view. I don't see any excuse for debauching, because it is invariably damaging to something. So for me the most significant thing about brandied fruit, for better or for worse, is that it has an alcohol content. It makes a heady dessert—and not one that children can have very much of—so you don't need much for a winter's supply. Tutti-frutti is the most common and versatile sort, because you can eat it straight, use it for an ice cream or general dessert topping, or make a sort of fruit cake out of it (actually better than eating it straight).

Incidentally, baking or boiling evaporate most, but not all, of the alcohol in any recipe. Despite the cooking, 10–15 percent of the alcohol will remain. You can indeed get intoxicated from fruit cake—if you eat enough of it.

**Earlen's Tutti-Frutti** You can start with 1 1/2 c. fruit and 1 1/2 c. sugar. For your first mixture, half-drained crushed pineapple and half-drained chopped canned peaches are good, along with 6 chopped maraschino cherries. (Peaches brandy best, and after them cherries.) A package of dry yeast stirred in helps to get the fermentation off to a quick start. Stir it several times the first day. At least every 2 weeks after that, add 1 more c. sugar and 1 more c. fruit. Alternate your fruit so you don't end up with all the same thing. Don't put it in the refrigerator, but don't have it too near the heat either.

Once you get it going, you can give a cup of "starter" to friends, who can soon work up their own supply of tutti-frutti from it. The mixture is at its best after 4 weeks have passed. You can take out fruit to use as needed, but try not to let what's left get below 1 cup. To have more, just add more fruit and sugar ahead of schedule. You can use fresh, canned, or frozen fruits such as Bing cherries, raspberries, blueberries, apples, pears, or fruit cocktail as well as the first ones I mentioned. But if pears and fruit cocktail are used, treat them gently so they don't become too mushy. Don't use bananas.

Be sure to keep the fruit under the liquid. You can use a weighted saucer to hold it down. Fruit exposed to air will darken in color and taste too fermented.

**Old-Time Tutti-Frutti** The first recipe I gave you is quite common around the country now and implies some city-type living with the maraschino cherries and pineapple.
Here’s a way to make tutti-frutti from your own garden and orchard, a sack of sugar, and a cup of brandy.

Start this at the beginning of the fruit season. Strawberries are probably the first fruits you’ll have and are great for this purpose. You can start in a jar and transfer to a crock as your supply grows. I’d suggest keeping it in the coolest place you can find during the summer. As the season goes on, add cherries, apricots, plums, nectarines, and peaches. Avoid apples, pears, melons, and blackberries.

Into the jar put 1 c. very good brandy, rum, or cognac, 1 c. sugar, and 1 c. fruit. Stir and let rest. Don’t refrigerate. Cover to keep the dust out but don’t seal. As each new fruit comes along, add it and more sugar, at the rate of 1 c. sugar per 1 c. fruit. You don’t need more brandy. Cut large fruit into small pieces and stir well at each addition. Take out pits and seeds where appropriate.

If you figure 3 months for it to mature, it will be about ready by Christmas time. Serve over plain pudding, cake, or ice cream. Or make a fruit cake or a holiday fruit bread with it.

Almost Instant Brandied Fruit

Use canned fruit. Apricots, peaches, pears, and so on are all right. Save the juice from the fruit and boil it down to half the original amount. Add 1 part brandy to 2 parts of your boiled-down syrup and pour that over the fruit. Let it rest at least 24 hours before serving to let the fruit absorb the flavor.

Rum-Brandied Fruit

You can also make brandied fruit using rum. Mix 2 c. well-drained fruit with 2 c. sugar. Cover well with rum. It takes about 1 1/2 cups. Just as in the other recipes, you then can add more fruit and sugar every week or two to keep it going.

Almost Instant Brandied Fruit

Use canned fruit. Apricots, peaches, pears, and so on are all right. Save the juice from the fruit and boil it down to half the original amount. Add 1 part brandy to 2 parts of your boiled-down syrup and pour that over the fruit. Let it rest at least 24 hours before serving to let the fruit absorb the flavor.

Tutti-Frutti Ice Cream

Soften store-bought vanilla ice cream or make your own. At the very end, add tutti-frutti and refreeze or freeze.

Tutti-Frutti Fruitcake

Mash 1/2 c. butter together with 1 c. sugar until well mixed. Add 4 eggs, 3 c. flour, 2 t. soda, 1 t. cloves, 1 t. allspice, 2 c. your brandied fruit of any sort, 1/2 c. applesauce, 1 c. raisins, and 1 c. nuts. This bakes best in an angel food-type pan because it is very moist — a buttered 9-inch tube pan would be right. It takes a long time to bake — 70 or 80 minutes or more in a moderate oven (350°F).

Combination Spicing and Brandying of Peaches

Peel about 4 lb. peaches. Dissolve 4 lb. sugar in 3 c. water. To spice with cloves alone, insert 2 whole cloves in each peach. To spice with cinnamon and cloves, put 1 t. stick cinnamon and 1 t. of whole cloves into a spice bag and boil with the syrup. Put in the fruit a little at a time and boil each 5 minutes. When done, remove the fruit to jars and boil the syrup about 10 minutes, or until thick. Pour syrup over the fruit to fill the jar two-thirds full and then finish filling with brandy. Remove the spice bag when syrup suits your taste test for spiciness.

Rummed Blackberry Juice

Steam 4 1/2 qt. blackberries until the juice starts to flow. Strain in a cheesecloth bag until you get all the juice you can. Add the juice of 3 lemons and 4 oranges to the blackberry juice. Bring to a boil what you have left of the blackberries with 6 c. water; strain again and add that to your juice. Add 2 c. sugar. Now bring juice just to a boil and add 2 c. rum. Can or bottle it. (You could substitute brandy.)

Rummed Blackberry Juice

Steam 4 1/2 qt. blackberries until the juice starts to flow. Strain in a cheesecloth bag until you get all the juice you can. Add the juice of 3 lemons and 4 oranges to the blackberry juice. Bring to a boil what you have left of the blackberries with 6 c. water; strain again and add that to your juice. Add 2 c. sugar. Now bring juice just to a boil and add 2 c. rum. Can or bottle it. (You could substitute brandy.)

Brandied Cherries

Boil 5 c. sugar with 2 c. water for 12 minutes, or until you have a clear syrup. Pour that syrup over 5 lb. cherries (the small sour kind) and let stand overnight. Drain off the syrup and boil it again. Add cherries and boil about 5 more minutes. Take out cherries with a skimmer (the kind with holes in it to let the juice drain away) and put the cherries into canning jars. Boil the syrup down 15 more minutes. It should be getting pretty thick. Add 2 c. brandy. Remove from heat. Pour over cherries and seal.

Buried Brandied Peaches

I think the very best brandied fruit of all is made by this recipe. I found it in an antique book, and Mike and I tried it out of curiosity. I imagine it would work with any fruit, although we used peaches. This recipe needs no brandy, only fruit and sugar. Choose fine, ripe, very sweet peaches. They must not have bad spots. Peel them. Cover with whole peaches the bottom of something you can bury. Pour in enough sugar to cover them. Add more peaches and then more sugar in the same manner, until you are out of peaches or room in your container. Cover very tightly, but not absolutely airtight, and bury in the ground for 4 months or more. We put ours about 3 feet down, which made the top of it about 2 feet down. Mark the spot so you’ll know where to dig it up.

I was really afraid dirt would get into it, but not one speck did. We put it down in peach season, just outside the back door, and dug it up for Thanksgiving (which isn’t a full 4 months). The floating top layer, the part that was out of the liquid, was discolored and yucky-looking from oxidation. We threw that away. What was left was brandied peaches of a quality the likes of which I’d never seen before. The peaches’ color was perfectly preserved; they looked just as they had the day we put them in.

But they darkened very fast when exposed to air; within 24 hours we could see and taste the difference as they commenced to deteriorate. Apparently exposure to air was causing the trouble. If I had it to do over, I’d reseal them in smaller jars as soon as we dug them up and just open them as needed, so there would be as little exposure to air before serving as possible. You absolutely must keep any brandied (or spiced) fruit below the liquid and out of the air, but this stuff was even affected by the exposure of the liquid to the air.

I think the temperature control also helped make it good. I imagine if you sealed a crock of tutti-frutti and buried it the same way for 3 months, it would do as well, because the temperature underground is evenly cool but not too cold — especially early in the season, when above ground it’s hot. Brandied fruit made from scratch needs a cool temperature, since you don’t have the help of the preservatives that are in store-bought foods.

February 1975. Dolly had hurt her knee, went to the doctor, and got a crutch. I thought then she’d soon be fine. I had no idea that the next morning she would be unable to walk on the remaining good leg. Subsequently, both arms went bad, then neck and back. It all turned out happily in the end, but the end was much longer in coming than I had expected. She’s much, much better now than she was in the middle of January, when there were days when she could not use her hands even to turn the pages of a book or to feed herself. In fact, she seems very nearly well again.

The doctors predict she is almost certain to suffer another, worse attack within a relatively short time. But that's
doctor and done. Dolly is well now, and she's going to stay well. I'm going to take such good care of her that the old bug, whatever it is, doesn't have a chance. And this isn't the first time my opinion parted company with the doctor's and I won. There's too much at stake here for me to agree with something like that. God will guide my hand in nursing her, and He's the greatest Physician of them all. [She never did have an attack of arthritis again. Dolly's nearly 30 now, married, with children of her own.]

I used to have a section about making candy—but I had to cut it (not enough space). It had the basics like taffy, and some fancier things too. But making hand-dipped chocolates and marzipan and other fancy candies belongs more to arts and crafts than to cooking, I think. I can't really reconcile myself to the notion of spending all that time and labor to make something so beautiful and then opening my mouth and wiping it out. Same for cake decorating. I enjoy the fancy decorated cookies the grandmas around here make for Christmas. But when people have the creative urge, you just have to get out of their way and let them go. I used to write poetry, and maybe that's just as useless a product as a cookie or cake decoration—and maybe more so because it isn't even edible. I tried to sell my poems by mail once. Out of a mailing of several hundred, 2 dear people responded—more to keep my morale up, I think, than for the sake of the poems.

When Mike was a student in the big city, I used to take my poems down to a street corner in Greenwich Village (along with a baby or two), put on a great big sandwich board that said "Poems for Sale" on each side and sell copies for 25 to 50 cents apiece. (Mike priced them for me.) I barely made enough to pay my bus fare and buy lunch, but it was really beautiful just standing there sharing my Villlage (along with a baby or two), put on a great big sandwich board that said "Poems for Sale" on each side and sell whatever it is, doesn't have a chance. And this isn't the first being on the receiving end who can laugh and care and reconcile myself to the notion of spending all that time and labor to make something so beautiful and then opening my mouth and wiping it out. Same for cake decorating. I enjoy the fancy decorated cookies the grandmas around here make for Christmas. But when people have the creative urge, you just have to get out of their way and let them go. I used to write poetry, and maybe that's just as useless a product as a cookie or cake decoration—and maybe more so because it isn't even edible. I tried to sell my poems by mail once. Out of a mailing of several hundred, 2 dear people responded—more to keep my morale up, I think, than for the sake of the poems.

Vinegar

Vinegar is high-acid and thus is the basis for another sort of natural "chemical" food preservation. I've never managed to make it—not for lack of trying, and not because it can't be done. A dear old lady in Juliaetta named Mrs. Eggers took my recipe and made wonderful vinegar from it, absolutely the best wine-type vinegar I ever tasted. And she ended up with a "mother" (a thick substance that vinegar-making critters live in) that was like a colored firm-but-clear gelatin, just like you're supposed to. She even gave me the mother after she got done making vinegar. I brought it home and tried to make vinegar out of it: still no luck. For the time being, I've given up.

My last attempted batches were in the living room. One was a jar of mixed grape and peach wine. One was a big crock of malt stuff that I hoped would become malt vinegar. And, oh yes, there was also a yet larger crock of rotted apple peels and cores on the way to becoming cider vinegar. They all smelled so bad it got to be a social problem. Like the day Dolly's music teacher got a funny look on his face and gave a very short lesson (the piano was in the same room, and I never explained about the crocks). One fine day soon after that, Dolly was sitting on top of the (unused) stove, playing, and she fell off splat right into the biggest crock of all. She gave out an anguished cry—half embarrassment and half pain. By the time we got her fished out of there, all 3 containers were either spilled or contaminated, so I called it quits for the time being. So I'm going to tell you how Mrs. Eggers makes vinegar.

To get the right cultures (and home boiling gear), check the Yellow Pages under "Beer Homebrewing Equipment & Supplies" or "Winemaking Equipment & Supplies." Or get a list of suppliers from The American Homebrewers Association, Box 1679, Boulder, CO 80306. Or . . .

Alternative Beverage, 114-0 Freeland Lane, Charlotte, NC 28217; 704-527-9643.
Beer & Winemaking Supplies offers hard-to-find mead vinegar cultures: 413-586-0150; 154 King St.,

PRESERVING WITH VINEGAR, SALT, AND FAT

Pickles

The "Cucumber" section in Chapter 4 has lots of information on crock and canned cucumber pickles. But you can actually pickle crook just about anything using different combinations of salt, sugar, vinegar, and spices. Cured meats like ham, bacon, and corned beef are made using salt and sugar, with the addition of saltpeter (makes foods red and helps preserve them). Dill pickles use salt and vinegar, leaving out the sweetness. Spiced fruits leave out the salt and put in sugar, vinegar, and spices. Krauts and salted-down vegetables are vegetables and salt only. (See "Cabbage" in Chapter 4.) These ingredients aren't there just for flavoring. Salt, vinegar, and (under certain circumstances) sugar are the original chemical preservatives.

There is a nearly infinite number of different ways to pickle different foods, depending on your choice of picklers, how strong they are, which vegetables you choose to pickle, and just how you go about it. There are some great books on pickling in your library or bookstore.
An old iron pot was in the middle of the building where a
Adding yeast makes the alcohol stage get going faster.
Adding the mother helps the acid formation from the alco-
were made of hewn oak logs, with a solid door and one cat
wastes (peels and cores), which is really not bad. You can
nowadays? Commercial cider vinegar starts with apple
propped open to let in air. The barrels were stored in the
vinegar, only what we put on the Swiss chard at dinnertime
isn't nearly as strong as what they use in the laboratory.
Eggers did it that way.
A lady who read what I had written before this wrote
me, “When I was a child some 50 years ago, the apples
were ground in an old outside cider mill; then the juice
was pressed out with a wooden press, yielding 50-gallon
barrels. They were wooden barrels with wooden lids. A
large cloth was tied over the top of the barrel and the lid
propped open to let in air. The barrels were stored in the
smokehouse to ferment all summer. The smokehouse
isn't nearly as strong as what they use in the laboratory.
Adding yeast makes the alcohol stage get going faster.
Adding the mother helps the acid formation from the alco-
hol, because it adds the right kind of organism for that
change. If you don't use either yeast or acid, eventually
the right kind of critters will just fall in from the air. Mrs.
Eggers did it that way.

Well, back to how you can make vinegar like Mrs.
Eggers . . .

WHAT'S IN VINEGAR: You can't use store-bought
vinegar to hurry your vinegar making, because if you add
vinegar in the first step, while you are making wine, the
vinegar will tend to mess up or stop that reaction. Adding
it to the second stage, when you want the wine to turn to
acetic acid, will do you no good because the store vinegar
is all pasteurized so the needed beasties in it are dead.
You can use unpasteurized homemade vinegar for that
purpose, however.

Starter Foods. Vinegar flavors and acidities vary accord-
ing to the kind of juice you start with. You can make
vinegar from any fruit juices, even from the leftovers
from your fruit canning—the peelings and corings of
peaches, pears, apples, grape hulls, and whole cherries.
Mrs. Eggers made hers from apple peels and cores. Cider
vinegar means you started with apple juice (cider) or some
apple product like peels and cores. White vinegar starts
out from grain. Malt vinegar is made from barley. You can
make vinegar from any homemade wine but not from
cheap store-bought wines, because those contain preser-
avatives that would prevent the second-step fermentation
you need. Some expensive imported wines can be used because
ey don't contain preservatives.

FERMENTATION STAGE 1: MAKE ALCOHOL: This is
identical to the process involved in wine making except that
to make vinegar it isn't necessary to have perfect fruit, and
for vinegar you won't want as much sweetening, although
you could add sugar or molasses to beef it up. Or anything
sweet—leftover sweetened tea, leftover canned fruit juices,
jellies, sugar-bowl rinsings.

Container and Cloth. Put your starters in a crock,
wooden or stainless steel container, or glass jar. Never fer-
ment in aluminum or chipped enamel containers. Leave from
a half to a fourth of your crock space empty for later addi-
tions—you can add more makings every day for a while,
adding a little more water each time—and general bubbling
up. Cover with a clean cloth and tie it firmly around the
neck of your container with a string to keep bugs from
falling in and dying. That crock is going to be sitting there
a long time, and if you aren't careful the contents will get
dirty. Wash and replace the cloth once a week. Set the crock
in a warm place—80°F is a good temperature. It will work
at a cooler temperature, but the cooler the temperature, the
longer it takes.

Bubbles. During the first fermentation stage, it bubbles.
As long as that stage is going on, you'll be able to see the
bubbles coming up if you hold a match over the surface.
If it won't bubble for you, or if you want to hurry it up, or if
you want to be sure the right kind of microbes move in,
add 1 T. yeast to get it working. While it's bubbling, it's
“working.” When it gets done bubbling, it's ready for the
second stage.

FERMENTATION STAGE 2: ALCOHOL TO ACID:
When the sugar-to-alcohol (primary) fermentation is totally
completed, you're ready for the secondary fermentation,
which changes the alcohol to acetic acid. Vinegar is a dilute,
household-use solution of acetic acid.

Transfer. Siphon, dip, or strain the liquid from your
fermentation crock to a (dark-colored) glass, enamel,
wood, stainless steel, or pottery container, leaving behind
the sediment. A wide-topped container is helpful because acetic bacteria need oxygen to do their work. Fill no more than three-quarters full. Use a cloth cover, same as before. While it's working, store your becoming-vinegar container in faint light (sunlight holds the change back) and warmth.

Getting the Vinegar Beasties. Now I know why Mrs. Eggers could make vinegar and I couldn't. She caught the acetic bacteria, without which you can't make vinegar. They're carried both through the air in general and on the feet of vinegar flies! But you're always at risk of getting your crock infected by one of the bacteria and molds floating in the air that do not change sugar to alcohol or alcohol to acetic acid. In that case you could end up with a disgusting mess, which is what happened to me—unless you start Stage 2 with a fairly high-alcohol solution, which would protect it from just about everything except the acetic bacteria. But it's easiest, quickest, and surest if you can start by putting some mother in there.

Mother. This thick, clear, jellylike amber substance is made by the kind of beasties that make vinegar, and they live in it. If you've got some to add to your crock when you're ready to get Stage 2 going, you'll soon have the nicest vinegar you ever tasted. If you don't have it, you may be able to buy it from a health food store or a winemaker's supply house. Using mother can make a big difference in time as well as taste. If you don't have any mother to add, it could take as long as 6 months to complete your first batch of vinegar, because you must wait for the right kind of beastie to be brought by the vinegar flies.

When that does happen, the crock surface will gradually start to show a thin graying film floating on top. This is your mother getting started. Don't disturb it. It's important that the mother stay on top until its work is done. It will settle to the bottom of your crock, heavy and thick, later on. Taste occasionally to see how sour your vinegar-to-be is becoming.

How Long? The length of Stage 2 can vary greatly. It depends on whether you have some "mother" or have to wait till you catch some vinegar microbes, and on the temperature during the fermentation. In general, at 75-90°F cider should turn to vinegar within 4 months, but it can happen in as little as a few weeks or take as long as 6 months.

Care of Mother. Don't lose your mother now that you've got her! Strain it off. To store, just put it in a jar, cover with vinegar, and put a (non-metal!) cover on the bottle. Or keep a batch going continuously.

Bottling: Strain off the vinegar and put it away safely. Strain the vinegar out of your crock until it's "clean" enough to suit you; 3 layers of cheesecloth are about right. If the vinegar is sufficiently strong (made from full-strength hard cider), you can bottle in sterile bottles, seal, and store as is. If the vinegar was made from incompletely fermented cider, pasteurize it before bottling to avoid the possibility of it making more bubbles and blowing the bottle. When capping any container of vinegar, don't use plain metal lids, because vinegar corrodes metals! So seal with a cork, a cork-lined cap, or some such.

From the time of sealing, the vinegar will gradually grow more mellow and more distinct in flavor, although you can use it immediately if you want. This homemade vinegar can be used as a "starter" for your next batch. But it will keep best if you pasteurize it.

Pasteurizing (or Not). If you pasteurize your vinegar, it can't be used as a starter. If you don't want to pasteurize the vinegar, strain it through a wet, doubled cheesecloth before bottling and then store in a cool dry place.

But pasteurization will keep your vinegar from clouding due to formation of mother. Put the bottles or jugs of vinegar into a pan filled with cold water. Heat the water gradually. Be sure the bottles are loosely corked or unsealed while pasteurizing. Then heat until the vinegar is about 145°F and hold it at that temperature about 30 minutes. Then cool it.

Cider-Sediment Vinegar. Lois Rumrill, Forks of Salmon, CA, described her vinegar-making system for us: "When we make cider, I let it set in jugs for at least 24 hours and siphon the clear juice off the top of each jug, which leaves 1-1/2 inches of sediment. [Lois doesn't mention the time for Stage 1, I'm sure it was in there.] I then pour the sediment into glass gallon jars, add mother to each, cover with cheesecloth and a cocked lid, and let it go to work. Lo and behold! In almost a month . . . vinegar! I remove the mother (to another gallon jar containing vinegar), siphon the vinegar into a kitchen bottle, do not pasteurize. I pour the vinegar into a large pan, turn on heat, heat vinegar to 170°F, and hold at that temp for 10 minutes. Pour it into hot jars, seal, and store. Or sometimes I don't pasteurize—just let the bottles of vinegar keep forming mother. When I use those unprocessed bottles of vinegar, I just put the mother into that gallon jar with the rest of my mother. My vinegar tastes so very much better than store-boughten!"

FRUIT-HARVEST LEAVINGS VINEGAR. When you are processing a bunch of apples, peaches, pears, grapes, or cherries, wash them thoroughly before preparing for use and save the peelings, hulls, cores, or seeds as appropriate. Place them in a crock. Sweeten well. Add enough water to cover them. You can sweeten with honey, molasses, or sugar. Let stand several days, keeping the top covered with a cloth. You
can add fresh peeling now and then. The scum (mother) on top will gradually thicken. When the vinegar tastes right, strain and bottle. Another method is to let you peelings, water, and sweetening stand several days; then strain and let the resulting juice stand until you have table vinegar.

**PURE CIDER VINEGAR** Sylvia Nelson, Hillsdale, WY, wrote me, "I've made both malt and apple cider vinegar. The trick to making good cider vinegar is to start with cider, not apple parts. I sweetened it somewhat (white sugar does fine), added a few grains of yeast (I'm impatient), put a cloth over the jug, and left it in a warm place until done. The more sugar, the stronger the vinegar."

**WINE VINEGAR** You can make your own wine vinegar by starting with homemade grape or dark berry juice. Dilute; sweeten and mix, if desired, with a lighter juice such as peach. Keep in a warm place, covered. First it will ferment. You'll see the bubbles of carbon dioxide rising poetically as it works. Then it will go flat and your vinegar making will begin; that takes much longer and is less dramatic. You don't have to have mother to start. It speeds things, but unless you live in the frozen north, mother is all around us. In the South you may end up with father, aunt, and uncle too.

**APPLE COMBO VINEGAR** Combine a fruit juice with a tart apple juice. Pear is good. If you don't have a juicer, it will be easiest for you to just wash and mash the fruit by stomping with your kraut stomper. Then let it work until you like the vinegar flavor. Strain and store in glass in a cool dark place.

**USE OF VINEGAR:** It has a multitude of uses. In general, wine vinegar makes the best salad dressings, while apple cider vinegar is used to make pickles and ketchups—and vinegar flavor. Strain and store in glass in a cool dark place.

**Strength of Homemade Vinegar.** Commercialized vinegars have a standardized acid content; they are diluted to a predetermined strength and then pasteurized and bottled. Homemade ones vary in strength. A plain hard cider with no sweetening added will develop about 6 percent alcohol, which in turn will become about 6 percent acetic acid, which is a good strength for kitchen use. If you start out with sweetened liquid, your vinegar will be stronger. Take that into consideration when you are cooking or pickling with it. Or dilute to the strength you want with distilled water. To strengthen the vinegar, let it freeze on top. Then take the ice off the top, since only the water portion freezes.

**Shrub.** The base for the beverage called shrub is a vinegar-fruit mix. To serve, dilute it to taste with water or ginger ale. Great-Grandmother liked it served hot for coughs and colds in winter and as a chilled beverage in summer. When bottle, it will keep for years.

**BLACK CURRANT, RASPBERRY, OR BLACKBERRY SHRUB** Wash 2 lb. berries. Remove stalks and stems. Put into a crockery bowl and crush very thoroughly with a potato masher or pestle. Pour over the fruit mush 2 c. white vinegar and let stand for 5 days, stirring every day. Strain through a cloth. Measure the resulting juice and for every 2 c., add 1 lb. sugar. Boil very gently for 10 minutes, removing any scum. Strain again. Pour into bottles, cork, and seal with paraffin. (Stores that handle beverage-making supplies carry corks. The grocery store has paraffin.)

**RASPBERRY OR STRAWBERRY SHRUB** Add enough vinegar to cover 1 gal. red raspberries or strawberries. Let them stand 24 hours, scald, and then strain. Measure the juice. Add 1 lb. sugar per 2 c. juice. Boil 20 minutes and bottle.

**SPICED RASPBERRY SHRUB** Put your raspberries in a crock or jar. Cover with cider vinegar. Mash. Let stand overnight. Strain. For every 2 c. juice, add 2 c. sugar, 1 cinnamon stick, and 6 whole cloves. Boil 10 minutes. Bottle and seal while hot.

**Salting**

Salting is another method of food preservation. A 5 percent salt solution reduces bacterial activity, 10 percent stops most of it, and 15 percent stops anything. See "Cabbage" in Chapter 4 for instructions on making sauerkraut, a basic salted, fermented food whose formula can be applied to other vegetables (corn, green beans, turnips). Carrots, beets, and turnips keep well if peeled, shredded, and salted. They also do well in a root cellar. String beans and corn cannot be stored in a root cellar, but they salt well. Peas and onions do not salt well, but peas dry well and well-cured onions store well if put away on a shelf where they won't freeze. Peppers, green beans, and asparagus salt well but need to go into a brine rather than be put down in dry salt. For more information, see Making Sauerkraut and Pickled Vegetables at Home: The Original Lactic Acid Fermentation Method by Annelies Schoeneck.

**NOTE:** Never use galvanized containers for pickling—acid or salt works on zinc and makes a poison.

**DRIY-SALTING VEGETABLES:** Any root vegetable should be peeled and then sliced or chunked. Corn should be cut off the cob and string beans snapped into sections. Use a glass, crockery, or wood container to store the food—nothing made of metal, unless it's stainless steel. You'll need about 1 lb. salt for every 4 lb. vegetables.

Put a layer of salt on the bottom of your container, then a layer of vegetable, then salt, and so on until it is full. You can add more at later dates as your crop in the garden is ready for harvest. When you have as much vegetable in there as you want (don't go clear up to the brim), pour a in final layer of salt. Lay a plate on top, weighted down with a boiled stone, a jar full of water, or some such. Lay a cloth over the whole thing to keep flies from dying in it.
Let rest 2 weeks, changing the cloth weekly. The salt will draw the natural juices out of the vegetables and create a brine. When you need food, take some out and replace the plate. You must keep your vegetables out of contact with the air. Add more water as it evaporates to make sure that the water level is always higher than the vegetables.

**Brine Salting Vegetables.** With peppers, green beans, and asparagus, lay vegetables whole in your crock. Pour over a brine of 3½ lb. salt per 1 gal. water. Then follow the rest of the dry-salting instructions above. You can salt down in canning jars too. For example, pack green beans down in jars between layers of salt and then close up the jars.

**Serving:** Any salted vegetable must be freshened by soaking overnight in several changes of water and then promptly cooked. A vegetable that has been preserved in salt will spoil amazingly fast once the salt is rinsed off, so you must be very efficient in getting it from your brine crock, through the freshening waters and the cooking, to the table.

**Larding**

Another old-time method of food preservation is "larding." The French call larded bird meat a "comfit." Julia Child's *The Art of French Cooking* has a chapter on this process, using goose fat. The fat seals the air out. August Bartelle, San Diego, CA, remembers: "After slaughtering a hog, the fat was rendered into lard. Those cuts of the hog that were not fried were fried. While still hot, these slices of pork steak were preserved through the winter by larding. In a large crock, layer on layer of the fried steaks was covered with hot lard. This meat was then used through the winter by scraping the lard off each layer. The amount necessary for a meal was removed and reheated. The used lard was reused in pies or other baking or cooking and ultimately for soap."

FE Pennington, Kelso, WA, wrote me about her pioneer childhood: "I was raised on a stump ranch in western Washington. We grew what we ate and ate what we grew. If we didn't grow it, we didn't eat. We let nothing go to waste. Once Daddy killed a fat bear and larded it in its own grease. We ground the meat up and cooked it in balls, then packed it in a 4-gal. stone crock which was set in the spring. The spring was as cold as ice water where it emerged from the hillside. It worked."

**NOTE:** If you try this, make sure the food is stored under refrigeration, because there could be a botulism problem in that air-free, low-acid environment. The old-timers larded only in winter, through the freshening waters and the cooking, to the table.

**February 1, 1974.** I have to write up the "Butters" section, the "Beekeeping" section, the introduction to this chapter, the "Fruits (Apple to Pomegranate)" section, and the middle of the "Dairy" chapter—and then I'm done with this [first edition of] the book.

If you think that because I've written a book and I'm a Christian and I don't use white sugar (not to imply equality among these various qualities), I never had my troubles, let me tell you different. You don't know the half of it. But I've had my miracles too. And that's the important thing. And just making it—just having gotten one foot in front of the other and kept moving all day long no matter how heavy the foot and the heart felt—can be miracle enough in some situations.

Being this near to finishing the first draft of the book seems a miracle. A year and a half ago I made up my mind not to take it up again. My husband's preferred choice with regard to the book from the very start has been that I refund the money on all those early orders I took. I would have, only I never had the money again.

Then we came to one of those great marital shakeups that have to happen once every 5 years or so, I guess, and I got thoroughly shook up and swore off everything except what could make me a better housekeeper, wife, and mother. Not a bad decision. I did need strengthening in those directions. So I swore off the book and regarded it as a selfish desire and any further involvement with it on my part as in the nature of being tempted into sin. For one full year, I never touched the manuscript. For most of that year, I didn't think about it much because I was busy just trying to get the housekeeping in my head done and become somebody that God and I could be satisfied with.

But around last August, thoughts of the book started coming to me again—first, in terms of responsibility to the people whose money I had taken and spent, to whom I had promised so much by sending them, first of all, that ambitious table of contents. I had already sent parts of the book in three separate mailings to them all, and most of them were willing to consider that good enough, but a few were still holding me to that original table of contents. I'd left them all hanging now, without any further word, for a year. I've always been an almost painfully responsible person and, although I've had my fantasies of disappearing in the Underground or becoming a waitress in Tahiti, I don't expect it will ever happen. So I started to try to plan how to refund the money and get a letter out to everybody explaining why I had given up. But I just couldn't seem to get that done, even though it meant typing only one stencil and mimeographing it and mailing it out.

And the notion of finishing the book kept cropping up in my head more and more often, no matter how hard I tried to put it down. I regarded that oft-upcropping thought with almost tearful frustration: We had less money than ever, Mike had been laid off from the part-time job he had been working at in addition to his full-time one. I had less time than ever because when I started the book, I had 2 children, but I now have five. How could I buy paper with no money? How could I get the mimeographing done since I no longer had access to the machine at Mike's office I'd been borrowing (because I had broken it)? How could I pay for postage?

But the urge to write again just got worse and worse, even though just getting through the chores I had seemed to take all my strength. I'm not a lazy or puny person. (I had my fifth baby, Sara, on a Thursday morning, left the hospital Friday evening, and went home and commenced to catch up on the dishes and laundry.) But it seemed like I was at my limit, and being nagged by the urge to write seemed to make me even more tired. (That's a curious thing, because once I actually started writing, the sensation of weariness gradually left.)

But was the desire just mine? In my one year of experience with God's way of leading me, a thought that nags me, patiently, relentlessly—the "do this, do this, do this"—is one way God has of showing me His will. And that's the way the thought of finishing the book came to me, more and more.
One day I literally broke down. Kneeling on my living room floor, crying out with lifted hands, I said, “Okay, Lord. I submit. This seems to be Your will. I can’t see the way it’s possible, but if it’s Your will, I know You have a way through for me if I just go ahead and trust You.”

The next day, secretly, I went back to work on the book. I constantly sought for God’s leading with regard to the project and followed it explicitly. I had no hope outside His Power to accomplish miracles. I worked on it during daytime hours, while my husband was at his job. I did the displaced housework in the evenings: scrubbing floors and ironing shirts, usually until 11:00 at night. God gave me the strength. That was His first miracle for me. I was able to accomplish twice as much work as before.

When, weeks later, I finally felt it was time to tell Mike, he was good about it. That was a second miracle: Over the years past, Mike had grown to hate with almost a passion everything relating to the book and my work on it, but ever since then he’s been very patient.

INTRODUCTION

Domestic animals are basically human-created, symbiotic species. Most have been companions to people, caring for and being cared for, for literally millennia. For example, all but about 2 percent of the chicken varieties now sold in North America are breeds whose characteristics have been affected by careful selection by human breeders. Wild chickens, though they still run about in the jungles of Southeast Asia, are scarcely available for purchase elsewhere and would be impractical to own. The chicken as it now exists is dependent on its keeper to survive.

But in return for the responsibility you take for domestic animals' care, feeding, housing, and doctoring, your animals eat your garden waste, kitchen surplus, and the field plants that humans can’t eat, like grass and brush; and they turn it into high-quality protein foods for your diet (eggs, milk, meat). They also contribute manure to renew your pasture, field, and garden soil, and they devour insects. They can be used as pack animals; they can provide transportation, pulling power, and by-products such as wool, feathers, hides, and horns. Truly, they are benevolently symbiotic species that have been carefully evolved by fine farmers throughout the world over thousands of years to be the best possible companions, economic and social, to food growers. They are not imprisoned wild animals! Most would quickly become extinct if not cared for by people.

My humble friend Stephen Scott (who makes a living growing pork, chicken, and organic vegetables for mail-order and his local farmers’ market) has a wonderful way of putting things. He wrote me, “What raising pigs is all about, aside from the meat, is getting back to our roots as providers in a way that is much more important than just working at a job to put food on the table. I believe that the act of raising and caring for our own animals makes us more human.”

RESOURCES

BOOKS: There’s info about raising animals for meat in Raising Your Own Meat for Pennies a Day, by Will Graves (1983); Raising Animals for Fun and Profit, by the editors of Countryside (1984); Barnyard in Your Backyard, Gail Damerow, editor; and Small-Scale Livestock Farming: A Grass-based Approach for Health, Sustainability and Profit (1999) by Carol Ekarius (last two from Storey Books, address in Chapter 1). Organic Livestock Handbook, Anne Macey, editor, is a project of Canadian Organic Growers Inc. (www.cog.ca).

MAGAZINES: Ranch and Rural Living is a monthly about sheep, goats, and cattle: $25/yr; free sample; 915-655-4434; PO Box 2678, San Angelo, TX 76902. The High Plains Journal covers the livestock scene, too: 800-452-7171; fax 316-227-7173; PO Box 760, Dodge City, KS 67801; journal@hpj.com; www.hpj.com/.

MAIL-ORDER SUPPLIERS OF LIVESTOCK EQUIPMENT

Brower Equipment for Poultry, Livestock, Pets: Highway 16 W, PO Box 2000, Houghton, IA 52631; 319-469-4141; 800-533-1791; fax 319-469-4402; brower iowa@aol.com; www.browerequip.com. Free catalog of equipment for poultry, pigs, and cattle; mousetraps; high-tech incubators.

Klubertanz’s Equipment specializes in welded wire and hex mesh, 1 x 2 in. spacing and smaller, and supplies for small animals. Free catalog: 1165 Hwy. 73, Edgerton, WI 53534; 800-237-3899; fax 608-884-7509; www.klubertanz.com.

Modern Farm sells farm and ranch supplies. Free catalog: 800-443-4934 or 307-587-5946; 1825 Big Horn Rd., Cody, WY 82414.

Premier1Supplies offers goat/sheep supplies, fencing, clippers: www.premier1supplies.com.

Sheepman Supply Company provides a wide range of supplies to sheep, goat, cow, horse, llama, alpaca, and horse farmers, including shearing gear, health care products, books, and videos. Free catalog: 800-331-9122; 301-662-4197; fax 301-662-0361; PO Box A, Frederick, MD 21702; info@sheepman.com; www.sheepman.com.

LEARNING LIVESTOCK CARE: 4-H, your extension service, and agricultural college classes are all resources. All the counties of western Washington state have a program that produces “WSU Extension Livestock Advisers” after training in animal care, “from how to feed a llama to how to eliminate goat horns.” Although “master gardeners” are everywhere, right now that is the only livestock master program in the country; I hope others will soon start up elsewhere. For info, contact the program founder and guiding light: Mike Hackett, Skagit County Cooperative Extension; 360-428-4270; 306 S. First St., Mt. Vernon, WA 98273-3805; hackett@wsu.edu; www.skagitcounty.net/wwu.htm.

Heifer Project International is a charitable worldwide organization that provides a female animal to a poor family in return for their gift of a female offspring to another family to pass on the help: 1015 Louisiana St., Little Rock, AR 72202; www.heifer.org. They seek donations in rich countries and donate animals in poor ones.

Considerations About Keeping Animals

Home-grown meat and eggs will always taste better and probably be healthier for you. They may even be cheaper to produce than store-bought eggs. You may hope to sell surplus animals for a profit or meat, breeders, or pets. Or you may just want to keep the animals as food sources for your family, as pets, for their beauty, or to show at judged poultry events as a hobby—or any combination of those.

RESPONSIBILITY: A basic question to ask about raising any livestock is whether you can afford the space, time, nuisance, and expense of adding them to your family. They
may not be permitted by your local zoning. They may cause odors and noise and attract flies, mice, and rats. You won’t be able to take vacations unless you can arrange caretaking. No matter why you want to keep poultry or any other livestock, start small enough so that you can try out your management ideas without too much stress on either you or the animals, which will be dependent on your expertise, faithfulness, and ability to provide for them.

One of your most important responsibilities is simply being around your animals. You won’t be able to leave home without considering their needs. You can limit the responsibility and tied-downness of animal keeping by just raising a spring crop: buy a flock of young ones in the spring, raise them to butchering weight, transfer them to the deep freeze, and you’re done for the year. Your schedule may determine whether you choose a small egg flock of hens to raise year-round, or have a big meat-chicken production operation for just a few months a year—or do both. You can stay away from most egg flocks for a few days and they’ll be fine, but a bunch of meat birds requires daily tending.

Carol Caple, Neosho, MO, wrote me, “It really boosted my ego to read that someone else has troubles from time to time and that some other woman has had to chase escaped livestock while her husband was at work in his clean, air-conditioned office. People (me included) thought we had done something wrong when our one and only goat died of pneumonia. I now realize that nature takes its course and tending.

Your Animals’ 4 Basic Rights
1. Treatment when injured or diseased.
2. Freedom from extreme physical discomfort.
3. Sufficient and nourishing food and water.
4. Care that minimizes fear and stress.

Animal Psychology: Animals are different, but they’re all heavily endowed with instinct and subject to habit. You have to work with their instincts and instill good habits in them. Once your animals have gotten their routine established, you must patiently subject yourself to their rules. Take time to listen to them and learn what their noises, expressions, and behaviors communicate. They listen to you. They may not understand all your words, but they’ll understand some, and your voice's tone, facial expression, and body motions will communicate eloquently to them whether you’re pleased, angry, insistent, or indifferent. Rule them like you do children: you must have a history of 8 or 10 true kindesses before you will have earned the privilege of a moment’s needed educational discipline. When you come to see them, bring a treat. When you get an animal someplace you want it to go—the stanchion, pen, or pickup truck—reward with a treat. Animals you’ve handled since they were young will be more friendly and less fearful than those bought as adults.

Zoning: Before investing in any farm animals, small or large, check your local zoning ordinances. Animals make smells and noises and occasionally escape from custody, and the very ones you love may be regarded by your close neighbors as unbearable nuisances. Chickens and turkeys, in particular, smell because of the high concentration of ammonia in their droppings. So choose where to live with your farm family in mind, or choose your farm family keeping in mind where you live. I have had the experience of being visited by the town police officer and told I must either get rid of my animals (goats) or move (I moved).

Choosing Your Animals: You’ll be concerned with the hardiness of the varieties you buy, suitability for your situation, and length of time to slaughter. For example, broiler chickens go into the deep freeze after 8 weeks at about 4 pounds each; ducks go into the freezer after 8 weeks at 7 pounds each. Turkeys will weigh more at slaughter (15–20 lb.) but must be cared for longer (5 months) and fed more, and they’re not quite as hardy. Some animals can forage better than others and thus cost less to feed. For birds destined for a commercial meat market, white-feathered breeds are preferred because their pinfeathers (small, immature feathers that tend to remain in the flesh) are white and don’t show up. Every situation has individual angles you’ll want to consider. You may want just one kind of animal, or you may want an assortment.

Shawn Trumble, Ionia, MI, wrote, “When I first bought your book, we were living in a little apartment in town. The landlord wouldn’t even let us plant a few tomato plants. Now we have 3 acres (not enough!), a big garden, the start of a small orchard, 30 or so assorted hens, a pig, 4 assorted Jerseys including a cow we milk, a veal calf (good use for extra milk!), a few geese, and a turkey! The kids raise and sell broiler chickens in the summer and have a waiting list of people for the next batch. We also sell eggs. So we raise our own beef, pork, poultry, dairy products, eggs, fruit, and vegetables!”

Animal Economics: A lot of people who raise animals end up complaining that it costs them more to home-grow eggs and meat than to buy them from the store. They generally qualify that by adding that the meat tastes much better, and they usually believe home-grown is healthier. But cheap is desirable, too, and sometimes is necessary. With good management it’s possible to home-grow at a profit. To raise any animals, your basic expenses will be the animals (or their parents), their feed, their housing, and the equipment you need to raise them, such as feed and water troughs and a brooder lamp. Some things you can buy used at a bargain. Most housing and equipment can be used over and over again so that it becomes a minimal expense.

Farming is the only industry in which you buy retail and sell wholesale. It’s hard to make a profit, although the organic market has been growing and becoming more competitive. If you can afford only a small piece of land that
Any mammal that is trained to wear a halter and act appropriately on the other end of a lead rope is easier to live with than a halter-ignorant one.

1. Start as young as possible. Younger ones are easier to handle and easier to train. Be patient and gentle.
2. Start by getting up to and putting a halter on the animal's head.
3. Next, just tie up the animal for a couple hours to an immovable object. This gets them used to the idea that they can't get away and accustoms them to the feel of the halter. Tie up the animal with just a foot length between its head and the fence, or whatever it's tied to, so it can't get its legs tangled in the rope. If possible, tie it to a fence rather than an isolated post so it can't wind itself around it.
4. Repeat every day until this lesson is learned. Don't leave it alone at first. It might fight and choke itself. Grooming it while it stands there helps reassure and gentle it.
5. Take the animal into a small, totally enclosed space like a pen or corral (to keep it from escaping; an animal that has gotten away once will be twice as hard to train the next time). Practice leading it counterclockwise around and around. Don't tie the lead rope around your arm or body so there's no risk of being dragged. Keep the animal's head up and bent a little toward you. Practice about half an hour. Stop the practice for six hours or so. Then practice another 30 minutes. (Same-day practices really help!) Practice every day until it gets easy.
6. For a difficult large animal, it may help to first tie the animal to the back of a vehicle (a "leading gate"), which is then moved to lead the animal. Or tie the trainee firmly to another animal that already knows what it's all about, and lead them both in that way.
7. For your first out-of-corral leading, let your animal get a little thirsty, and then lead it to water.

won't run enough animals to support your family in a commercial operation, and yet you want to be a full-time farmer, there are two other ways to do it. One is raising organic meat; you get paid much more for the carcasses than you would otherwise (so you can make it with fewer animals). The other is raising registered animals. But both of these are somewhat risky, like all farming, and both depend a lot on your ability to sell yourself and your animals. It's also important to get into, and along with, the groups that promote these special products and breeds.

You'll have a vastly different approach to raising animals depending on whether you want to make money on them. If you have a few animals to help provide healthy food for your family, you'll know them well and be friends with them. But to profit from livestock, you have to operate like a business and view the animals more impersonally. Know what's possible: for instance, a calf can grow 100 pounds of meat for you in only 3 months (more meat quicker than any other animal), but it takes 10 years to develop a herd of 30 cows, even if you start with 3 beef cows with calves. On the other hand, one bred sow can have 700 descendants in three years. But also consider rabbits . . . and chickens . . .

Then set goals. Try to continually increase the quantity or quality of your product and have better cost control. Keep track of all you spend and earn, and regularly reconsider the project according to those numbers.

NOTE: P. Wells of Smallholder, the English homesteaders' magazine, wrote me: "Tell people to check local laws. There are several new guidelines on selling, processing, and producing foodstuffs, eggs, and dairy produce." That applies equally to readers in any country—or U.S. state, for that matter.

THE AUCTION RING: Cull cows generally go to the auction ring; some good cows do too. The Lewiston auction ring handles hundreds of animals every time it's in session: cows, pigs, sheep, and sometimes others. It's a sight to see. I was there once when they brought a Charolais bull through. Charolais is one of the new beef breeds, off-white and very big—a bull can be over 3,000 lb. This was a big bull, and he had horns and was in a horrible mood. It really had us nervous for a while because he was charging everybody in
sight and they couldn't even get into the ring to open the
gate to let him out. Finally a brave man dodged out into
one side of the ring and let the bull charge him (he got
away) while another person just managed to get the gate
open at least partway before the bull saw him and charged
him too.
**Traveling with Animals:** You need to be prepared
to travel with your animals. Even if the person you buy it
from agrees to deliver the animal, 2 days later you may
need to take it to the vet, or you may be mad enough at it
to want to take it back to the previous owner. A half-ton
pickup can hold any smaller animal, including a small
cow like a Jersey. (It can hold a bigger cow, but it's a real
struggle.) You'd have to bend a big Shorthorn cow pretty
near to an S-shape to get it in. A 1/4-ton pickup bed will
hold any cow or bull easily. You'll need stock racks, of
course, to haul cows. You can make your own. A 1-ton
truck can transport 3 big cows plus 1 or more calves tucked
in around the sides.

You can transport a goat in the back of a pickup most
comfortably by tying a rope to each side of its collar and
fastening the ends to each side of the pickup. That holds it
in the pickup so it cannot jump over the side. Or you can
tie it to the middle, right behind the cab, on a very short
lead. You can tie the legs of a calf or goat and put it in a car
trunk with the door a little open, but I don't care much for
that method. If you can spread out a big sheet of plastic so
your upholstery is perfectly protected, you can move one or
more goats, small pigs, or sheep in the back of a car. (Just
don't try to eat anything in the front seat during a trip with
goats, or you'll have goats in your lap.) You can bring a
newborn calf or smallish pig home in a gunnysack tied
around its body that leaves its head outside the sack.

I once traveled 60 miles in a small car with 5 goats,
3 young children, and myself very largely expectant. The
humans and goats made it fine, but it took the car a while
to recover.

**Genetics**

There are distinct genetic lines of poultry (and other ani-
imals) that go by the same name and yet have inherited dif-
ferences, some of which are beneficial and some of which
can be a problem. That's why it is helpful to always buy
stock from a breeder you trust. Genes matter. They define
what your animal's ancestors were and what your animal is
capable of becoming—what its strong points and weak-
nesses will be.

For example, the modern hen lays about 7 times as
many eggs per year as does a wild hen. This achievement is,
above all, the result of farmers' careful and continual selec-
tion of her predecessors for many generations. You can de-
cide what characteristics you want your poultry to have and
then obtain birds with those traits. If you decide to become
a breeder yourself, remember that good breeders ruthlessly
eliminate stock that doesn't meet their standards.

**Of Pedigreed Animals:** A pedigreed, or registered,
animal is one with known genetic characteristics. Its par-
ents, grandparents, and so on have been recorded. When it
is bred to another animal with known characteristics, you
know what sort of offspring you are going to get. There is a
long, valuable tradition of exhibiting the best breeding ani-
mals at the annual local county fair. So that's a good place to
go to study the breeds.

If you decide to raise registered animals, you will pay a
sizable price for your start of breeding stock. To start with,
you just breed and build up the numbers of your herd. You
don't eat any of the offspring. The registered stock is much
too valuable financially to be wasted on your dinner table.
You'll have to raise some cheaper animals for your family's
food. And you can't sell your registered animals through the
regular outlets—like a stockyard for cows on regular sale
days. You'll have to wait for a special sale of registered ani-
mals, and you might have to truck your animals quite a way
to get there. Or you sell them through ads in specialty mag-
zines. To sell pricey registered animals, each animal must
be carefully and thoroughly halter-broken and in tiptop con-
tion. And it's almost a must to take your best ones around
to all the stock shows you've got the time and money to go
to, because the more ribbons they win, the higher the prices
you can charge for them or their offspring.

You'll also join your state and national associations for
your particular breed of registered animal. You'll get a
monthly publication, and part of your dues will be applied
to the cost of the advertising that keeps up the national, or
even international, image of your breed. These associations
also usually put out a directory of members and sometimes
a handbook on caring for their breed; many sponsor an an-
nual convention or meeting. Many have affiliated state
groups that meet more frequently. If you happen into a
breed whose central organization has troubles, one that isn't
really meeting the competition in the national advertising
market, you may have trouble getting the top price for your
animals. To locate the society for any particular breed, look
in the Encyclopedia of Associations at your local library.

Who will you sell to? To people who think that a regis-
tered animal is so much better that they are willing to pay
the higher price. And to people like you who hope to make
money selling registered animals and are trying to get their
own start of breeding stock. And to parents of 4H'ers and
FFA teenagers looking for an animal that might win a prize
at the county fair. (They'll favor breeds that have recently
been winning.) And to people who have money and think
of owning registered animals as an upper-class thing. And
to large-scale livestock raisers who want to introduce partic-
ular characteristics into their herds. (For example, a dairy
owner may buy a purebred big meat-type bull (or artificially
inseminate with its semen) so the bull calves will sell at the
higher prices that beef with those characteristics brings.)
And to commercial operations that want to start with the
best or upgrade the stock they have. And to plain folks who
want a guarantee of no bad genes in the offspring.

**Bad Genes:** We had a problem once with a herd of
purebred cows that every so often produced a naturally
sterile heifer. (Now I know why they were cheap and the
owner was getting out of the business!) We have a heifer
out here now that was born without a tail and missing the
last couple of humps of her backbone. Otherwise she's fine,
but we won't use her for a brood cow, since the trait might
pass on. I had a 4-titted nanny goat once (they should have
2; cows have 4) who had 4-titted nanny kids. I wouldn't
keep her offspring for breeding either, since they might pass
it on. Some people say never to mate 2 animals that have
the same fault, but that's not good enough. If an animal has
a serious fault, don't let it mate at all. You don't want that
trait to continue.

**Artificial Insemination:** In some cases, you can
make more money selling semen from your animal than selling the animal itself. That's because it's cheaper to buy as many females as you can afford and artificially inseminate (A-I) them than to buy a champion male. You do that by buying frozen semen from the champion male of your breed. But even the semen may be very pricey. This method is sometimes used by cow breeders. You probably can take an A-I course somewhere in your area to find out how to do it. Check with your local extension agent or 4H leader.

If you set out to buy a registered animal, keep in mind that you're being exposed to an expert at person-to-person salesmanship. And be alert to the possibility that the animal is being misrepresented. Owners have claimed that their animals were bred when they weren't, and that they gave more milk than they really did. At such a high price, it pays to be very, very careful. Remember also that the owner is selling his or her own culls. An owner of registered animals is trying all the time to improve the characteristics of the herd: how much milk the animal gives if it's a dairy herd, how fast the calf gains weight if it's a beef herd. The animals offered for sale are the ones that don't meet the breeder's standards. You can't buy the best ones, unless you're prepared to pay fantastic prices.

A final summing up and advice from Carolyn Christman, program coordinator of the American Livestock Breeds Conservancy: "You can choose purebred animals or animals of unknown breeding. An advantage of purebred animals is predictability: you know exactly what the offspring will be when they grow up. If you choose purebred, you can then choose registered animals. Registered animals cost more. This cost is worthwhile if you are at all interested in the sale of breeding stock or in the development of a breeding herd. If you are making this kind of investment, shop around and find reputable breeders from which to start your herd. An auction can offer a bargain, but because things happen so fast, you can't do very careful buying. Don't assume that because an animal is stated to be a particular breed, it is. Look at the papers and make sure that they match the animal (check brands or tattoos if possible) before you pay extra for that registration! And make sure that the registry is a legitimate outfit. In short, do your homework!"

Heritage Breeds and Exotics

These aren't the same thing.

Heritage Livestock Breeds: These are old-time livestock breeds. Some are still popular, but many are quite rare and some have vanished forever. Back in the old days they were regular farm livestock, an essential part of rural life and agriculture. Years ago there were far more breeds of the 9 basic livestock species (asses, cattle, chickens, ducks, horses, geese, sheep, swine, and turkeys) worldwide than there are now. Back then, every area of the earth where people lived was a distinct eco-niche in which those humans and their specifically adapted animal breeds sustained each other. Modern times and agribusiness (mass) production of a very limited number of the most profitable breeds have caused the extinction or near-extinction of most of those other old-time domestic species. The mass-market producers tend to choose just one or a very few breeds and let the others approach or cross the line to extinction.

The preservation of these heritage livestock breeds happens on family farms that have a use for or an interest in such critters as pigs that thrive on pasture rather than in confinement (such as the Tamworth breed); poultry that will set and hatch their eggs; and a cow that is small in size and moderate in milk production (the Jersey). The Florida Cracker cow is adapted to the hot, humid climate of the Deep South. The horned, spotted Jacob sheep is a good survivor.

Commercial agriculture has zillions of the one breed most suited to agribusiness' mass production: Holstein for the dairy industry, Leghorns for the chicken industry, etc. But homestead-type folks keep the others going. The old-time breeds of livestock are worthwhile for their genetic uniqueness as well as their historic value. For example, someday there might be a disease in pigs equivalent to the hybrid corn blight. Rare breeds also may produce lovely colored wool, unusual cheeses, astonishing feathers, etc. And heritage breeds are typically better suited than industrial ones for the free-range, chemical-free homestead family's needs.

Carolyn Christman of the ALBC again sums it up: "These animals have better forage efficiency on pasture, maternal abilities, disposition, longevity, parasite and disease resistance, and general health. Their animal services—such as brush clearing, pest and waste control, production of manure, and grazing to improve pasture—are also quite valuable on the homestead farm."

I hate to spoil the fun, but I can't end this without sourly adding that some less common species have been left behind for good reasons, and the ALBC says only the good things about heritage livestock. Do your homework so you aren't disappointed.

NOTE: Before shopping for livestock, know exactly what you want your animals to be able to do in your particular eco-niche, or what market you are aiming their production toward. Then choose the most suitable species.

By the way, the American Livestock Breeds Conservancy works to protect nearly 100 endangered breeds of American livestock and poultry from extinction. They take a periodic census of all varieties of domesticated livestock in the United States. They name those at risk of extinction and encourage people to buy and breed them. If you join ($30/yr), you get a bimonthly newsletter, annual breeders directory, and access to a long list of reports and publications on rare and endangered livestock: ALBC; 919-542-5704; Box 477, Pittsboro, NC 27312; albc@albc-usa.org; www.albc-usa.org. Their newsletter contains classified ads for heritage breeds as well as a calendar of events like these: Country Fair and Crafts Festival, Hancock Shaker Village: Eric Johnson; 413-443-0188; PO Box 927, Pittsfield, MA 01202.

Exotics: An exotic breed is one that is either newly created, a once-wild native (such as buffalo!), or recently imported and new to the United States. For instance, have you considered raising butterflies? Contact Rt. 1, Box 447A, Mathis, TX 78368, www.butterflyrelease.com for more info. The Asclepias Seed Co. provides milkweed planting seed for nurturing monarch butterflies and larvae: 800-621-3696; 218 Prospector Dr., Ogallala, NE 69153.

You'll find listings of many rarer breeds of livestock at www.anst.okstate.edu/breeds. Their scarcity, the media interest in them, and speculators' hopes for profit make for risky business. The exotic market has on occasion seen
speculators making large profits — and the unaware taking large losses. The beefalo (a cow-buffalo cross) was once the center of bidding excitement, as were a relatively useless rabbit variety called the Belgian hare and later the ostrich. It’s safest to pay a price for an animal based on its potential to produce meat, work, hide, fur, or feathers rather than its potential as a breeder (rather than speculating, that is, that since you were willing to pay a mint for an animal, that means you’ll be able to sell its many offspring for a mint each too). That get-rich scenario runs into trouble when there are no more well-heeled speculators available to buy your animals — or when the media interest shifts to some other unfamiliar creature.

Nevertheless, there are good profit possibilities in raising exotics, so I’m not trying to totally talk you out of it; I just want to instill a healthy caution. Do consider raising species such as buffalo, ratites (ostriches, emus, and rheas), caribou, elk, antelope, water buffalo, red or fallow deer, cat-talo (another buffalo-cow hybrid), and South American humpless camels (“camelids”) such as llamas, alpacas, guanacos, and vicunas. You can sell to restaurants that want unusual meats on their menu and to people who want the meat or an unusual pet. You can sell exotic fibers (such as camelid wool). You can sell the animals for packing (the camels, packedlama.org), or performing draft work (river buffalo). In South America, guinea pigs (raised on a diet of corn cobs, grass, alfalfa, and lettuce) are butchered when they are 6 months to a year old. Their meat is an Andean special treat: “cuy.”

Exotics include breeds such as yak (International Yak Ass’n; www.yakpage.com). Also, there are now miniature breeds of cows, horses, goats, pigs, etc. Miniature horses, for example, stand 19 to 38 in. high. They’re too small to be ridden, even by children, but they can pull a cart. (Available from 520-682-8009; fax 520-616-7022; wowworks@aol.com.)

Humpless Camels. For expert advice on the medical problems of South American camelids, especially guanacos and vicunas, contact Dr. William L. Franklin:

billfranklin1@juno.com.

Llamas are said to be useful as livestock guardians. Doesn’t make sense to me that one could handle a bear, cougar, pack of wolves, or coyotes. (I recommend you get one or more Great Pyrenees dogs for this: www.c- efarms.com).

Here are lots more camelid info resources:

Alpaca Discussion List is for alpaca owners and those interested in them. The mailing list serves 700+ persons and is moderated by John L. Pinkowski (Pine Ridge Alpacas; 330-849-6435; alpacasite- owner@onelist.com; subscribe at www.onelist.com/group/Alpacasite.

AlpacaNet includes files about alpacas, their fiber, and directories of products and ranches; www.alpacanet.com.

Alpaca Owners and Breeders Association sponsors an annual convention: 970-586-5357; fax 970-586-6685; PO Box 1992, Estes Park, CO 80517; alpacainfo@aol.com; www.aoba.org; www.AlpacaOwners.com.

Canadian Alpaca Breed Ass’n: www.caba-alpaca.org.

Canadian Llama and Alpaca Ass’n: 800-717-5262; 403-250-2165.

Llama Information Exchange Newsletter is info about llamas and their issues, written by owners: members.aol.com/lamainfoex.

Llama Search’s site contains farm listings, info links, products, etc.: www.llamasearch.com/.

Llamapaedia was written by vet students. It covers husbandry, breeding, care, etc.; www.llamapaedia.com; www.llamaweb.com/.

Pack Llama Trail Ass’n: PO Box 25, Meridian, ID 83680-0025; ccllamas@mindspring.com.

Suri Alpacas are unique in the camelid family for their fiber, which hangs in long, separate locks rather than being woolly: surinetwork.org.

Useful Llama Items is a catalog for llama and alpaca owners offering halters, leads, medications, grooming and farming and training supplies, books, videos, shearing equipment, packs, harnesses, carts, wormers, specialty clothing, etc.: 800-635-5262; fax 815-234-7684; 5458 N. Rizoville Rd., Byron, IL 61010; www.usefullama items.com.

Camelids of Delaware sells guanacos: 313-545-2820; 130 E. Nine Mile Rd., Ferndale, MI 48220. Mettowee Valley Farm sells alpacas: 802-325-3039; fax 802-325-7023; PO Box 55, Rupert Mountain Rd., Pawlet, VT 05761; jcallen998@aol.com; www.mettoweevalleyfarm.com.

Seldom Scene Farm raises both llamas and alpacas: 606-873-8352; fax 606-873-1622; 1710 Watts Ferry Rd., Frankfort, KY 40601; sscene@lex.infi.net; www.seldom scenefarm.com. Or Tia and Peter Rosengarten: 802-824-8190; Mountain Pond Farm, 74 Obed Moore Rd., West on, VT 05161.

Deer/Elk/Reindeer Farming. Deer and elk farming is big business in New Zealand, which exports, and in the former West Germany, which consumes venison second only to beef and imports more than 25,000 tons per year [1989] and produces at least the same amount within the country. Commercial venison production is doing well in the United
States too. The first deer farm ever in this country was the Lucky Star Ranch in Chaumont, NY. An extension bulletin says Lucky Star Ranch raises 3,000 deer on 1,500 fenced acres and has done well with its own USDA-inspected slaughter and processing plant on the premises. Owner Joseph von Kerckerinck, founder of the North American Deer Farmers Association, sells fresh and frozen venison cuts directly to consumers by mail, but most deer and elk ranchers make arrangements with a cattle slaughterhouse to do that work.

Von Kerckerinck wrote me that the big start-up expense for raising deer or elk is a fence between 6 feet 3 inches and 8 feet high, which is a necessity. He says if you are raising fallow deer, you can keep 4 deer per acre; wherever you can pasture 1 cow, you can keep 6 to 7 fallow deer. Coyotes and domestic dogs are a problem for deer ranchers, but there are ways to make your pastures predator-proof. And for meat that may sell at $5 to $10 per lb., the risks may well be worth it. He sells a videotape on the subject: 315-649-5519; Lucky Star, 13240 Lucky Star Rd., Chaumont, NY 13622.

The H & A Ranch offers bison bulls, bred bison cows, elk bulls, and bred elk cows: 731-845-5671; 411 Redbud Lake Rd., Lexington, TN 38351; dainty@pchnet.com. For more info, order the Bison Breeder's Handbook and The Buffalo Producer's Guide to Marketing and Management from the National Bison Ass'n: 303-292-2833; fax 303-292-2564; 4701 Marion St. #100, Denver, CO 80216; david@bison-central.com; www.bisoncentral.com. ATTRA's article on "Bison Production" is at www.attra.ncat.org/attra-pub/bison.html. You can subscribe to the North American Bison Journal: 800-253-3656; fax 605-347-2525; bisonjournal.com. They have years of archived issues on their website.

Want to raise reindeer? Ethel Evans is Corresponding Secretary for the Reindeer Owners and Breeders Ass'n: 303-841-4098; 10190 Bayou Gulch Rd., Parker, CO 80134; moondeerranch@aol.com.

Ostrich. Ostrich hides make good boots, and ostrich meat is plentiful and good, but these birds can live for as long as 70 years and will keep producing beautiful plumes all their lives. You can't determine the sex of ostrich chicks until they're at least 8 weeks old. Ostrich chicks are liable to have nutritional problems and pneumonia unless well fed, warm, and dry. An ostrich hen can lay as many as 30 to 50 eggs a year, but not all the eggs will hatch. Abuse or teasing stresses the birds. They should not be left alone with small children, for they don't understand the strength of their peck. Their big bills snatch up a wristwatch, glove, ring, or buttons in an instant. Their strong forward kick protects them. They should never be left alone with small stock of all ages and can be a big problem if you live far from town. Rats usually kill only very young or very small poultry, but they can wipe out a hatch of chicks or ducklings in one night and can consume or ruin a lot of feed. Hawks hunt by day; owls, mink, skunk, raccoon, coyote, foxes, weasels, and ferrets, or they may be domestic dogs. Dogs are much worse than coyotes. While coyotes kill only to eat, dogs may kill a whole flock of sheep.

**Identifying Predators:** Your first problem is to identify the problem animal. Each variety of predator has a characteristic modus operandi, and if you discuss the details of what happened with old-timers in the neighborhood, they'll give you good advice. Mammals will take small stock of all ages and can be a big problem if you live far from town. Rats usually kill only very young or very small poultry, but they can wipe out a hatch of chicks or ducklings in one night and can consume or ruin a lot of feed. Hawks hunt by day; owls, mink, skunk, raccoon, coyote, foxes, weasels, and ferrets, or they may be domestic dogs. Dogs are much worse than coyotes. While coyotes kill only to eat, dogs may kill a whole flock of sheep.
**Predator-Proofing:** If the problem is your own pet, you must train it not to kill livestock, physically control it by fencing in or tying up, or destroy it—or you give up on that type of livestock and get something too big for it to kill—like a draft horse! You can predator-proof confined small animals by housing them in well-built quarters that predators can’t squeeze or dig into. You can protect against night predators by confining your animals in predator-proof quarters at least at night. Covering the top of your birds’ or bunnies’ outdoor runs keeps out both flying predators and disease-carrying wild birds. Some counties trap wild predators as a public service.

Rats can be a problem. Keeping feed grains in rodent-proof containers helps. Both rats and mice are attracted by poultry feed. It’s best to keep feed in covered metal containers like metal garbage cans. Keeping a mousing cat, trapping, or putting out poison grain are more combative approaches.

To protect animals in a herd, get a guard dog (918-967-4871; C&C Farms, Rt. 3, Box 6815, Stigler, OK 74462; bcoate@cisw.net; www.c-c-farms.com/). Read ATTRA’s article “Predator Control for Sustainable & Organic Livestock Production.” It’s free from 800-346-9140 or downloadable at www.attra.org/attra-pub/.

**Fire Ants:** An especially ugly and growing problem is fire ant predation. These newcomers to North America are gradually spreading through the southern United States. They are expected to spread eventually to western Texas, most of California, and through the Oregon and Washington coasts. Fire ants sting like a bee with a formic acid poison, are very aggressive, and will swarm over unmoving victims, possibly giving a fatal number of stings. They eat meat as readily as vegetable products. They attack anything alive and are most able to destroy young, slow, or otherwise vulnerable animals. So they can kill setting hens, baby chicks, and mother and baby rabbits. They’ve been known to attack calves, starting with their eyes. (They’re hard on wild animals too.) They basically eat everything from their victim but the skin and bones. Boiling water kills them.

**Chickens and Predators:** Make sure your chick area is safe from predators: dogs, cats, rats, weasels. Rats and weasels have been known to squeeze through 1-inch chicken wire. If you’re covering holes with wire mesh, the holes should be no more than ½ inch in diameter. Baby chicks can easily be squeezed to death by a carelessly tight grip. And, like other animal babies, they do best with a schedule that allows a lot of rest and a minimum of stress.

The facilities you plan for your poultry will reflect your judgment about what risks you care to take—as well as what existing housing there is, what you can afford, and what the individual species’ needs are. Living any life requires balancing the joy of freedom against the wisdom of precaution. Chickens love to roam, but then they’re more likely to get run over, carried off by a hawk, killed by somebody’s dog (maybe even your own), or afflicted by parasites. You may have to lose a few to find out just what the perils and limits to practical freedom are in your particular environment. You also have to consider the neighbors, because free-roaming chickens do not observe property lines.

**Dogs:** Dogs often are allowed to run loose at night, and sometimes they form packs that will chase and even bring down fairly large animals. If you see this happen or catch an offender in your trap, you have legal recourse and should use it, because it is never right for someone else’s animal to hassle or destroy your property—which includes your animals. A Havahart trap will capture, without injuring, 4-footed night prowlers, including somebody’s pet. You can order one from Rocky Top (865-882-8867; www.rockytopgen.com).

After the capture or identification, the next step is to tell the animal’s owner what happened. The owner should agree to control the pet in the future and offer to repay your losses. You bill him/her a just amount, the owner pays, and it’s done. If the owner will not cooperate, or if you do not know the owner, call the local animal control officer. Of course, if your animal causes damage to your neighbor, then you also have to do the right thing. It works both ways!

Dynah Geissal, homesteader and country-topics writer, suggests, “If at all possible, raise your dogs in contact with your livestock. You certainly don’t want to have to worry about your own dogs harming your animals. Unless you know for certain that your neighbor’s dog is good with livestock, do not allow it near your animals. Call or visit your neighbor immediately and make it clear that you will not tolerate their dogs on your property. Every livestock owner understands this.

“The trouble usually comes from people who think they can let their dogs run loose because they live in the country.

“The best defense against feral dogs and coyotes is a dog of your own. I’m talking about a farm dog, not a dog that spends its time in the house. It should be a dog that willingly and naturally protects your livestock. With a good dog on guard, a predator will usually look for easier pickings. (I have a Great Pyrenees and they are tops.) A gun is a last, but sometimes necessary, resort.”

**Barns and Fences**

Do a bunch of thinking before you start building. The design needs to be just right for the purposes it will serve.

**Building a Barn**

Homestead writer Don Fallick said, “Truthfully, most livestock need little protection from the elements, except for the wind and direct sunlight. They will need more feed in cold weather, though, if poorly sheltered. Of the many considerations involved in planning a barn, two of the most important, and most often neglected by novices, are animal control and manure handling. If you design your barn right, your animals will go just where you want them to, with very little effort on your part. Do it ‘wrong’ and you’ll be fighting your livestock several times every day. This can range from inconvenient, with goats, to hilarious, with chickens. With cattle and horses, which are bigger than you, it can be downright dangerous.” Wise words!

**Siting:** Where will you build your barn? You want a
place where water won’t be running into it and where there’s good drainage. Allow for unusually heavy rains. Make it strong enough to withstand the amount of snowfall you typically—and might atypically—get. Make it able to stay dry even when all that snow is melting in an off-season warm wind. Site where it will be easy to bring water and power to it. Don: “I know people who’ve been milking cows for 30 years in a barn with neither electricity nor running water. It can be done, and done well. But there will be times when you really wish for good, strong light or plenty of running water.”

**Building Materials:** My friend Stephen Scott and I are firm believers in recycling wherever possible. He said, “Many times you will be able to pick up building materials where you work. A lot of people won’t bother with 5-foot 2 x 4s or ones of any length that are sawn. Talk to the people who work in the shipping and receiving areas. Many times junk lumber will be thrown back in trucks or rail cars. Usually people will save some of it for you for the price of a cup of coffee. If this is not your situation, you can buy new lumber as a last resort. Think about places in your area where you may be able to get some construction material for free.”

**Flooring Materials:** Your barn will likely have a concrete, wood, or dirt floor. Each has pros and cons.

**Concrete.** Don: “Horse stables should not have concrete floors, even though this would make manure handling much easier. Impervious concrete keeps the urine trapped in the bedding and can cause hoof problems, even if the bedding is changed daily. One solution to this problem is to use sand for the floor. The sand soaks up the urine in the top inch or so, which can be shoveled out and replaced as needed, like cat litter. Eventually, it all needs to be removed and replaced, though, and this can be a very big job.”

**Wood.** Don: “A more traditional solution is to make floors of wood, 3 or 4 inches thick. This allows for raking as well as shoveling of the bedding, which is placed on top of the wooden floor. The problem with wooden floors is that they, too, eventually need to be replaced, which can be quite expensive.”

**Dirt.** Don: “The cheapest solution, and the least satisfactory from the standpoint of hygiene, is bedding directly on an earthen floor. The earth gets compacted by the horse walking on it and becomes as hard as concrete. It turns to mud where the horse has scraped away bedding material, which horses all do. It catches pitchfork tines and shovels nearly as much as wood, and needs to be removed periodically like sand, but must be broken up with a pick before it can be shoveled out. It makes for very heavy compost, which can be a real pain if you are handling manure without benefit of a tractor. But it’s literally dirt-cheap, and horses like it. Whichever method you decide to use, plan your barn so the flooring is easy to replace and level with the rest of the barn.”

**Design:** Don: “If you are going to keep several kinds of stock in the same barn, it is not necessary to design a special room just for each species. The same room that serves as a lambing pen in the spring can be used for raising goat kids or foals. The important feature of a properly designed barn is that every room opens onto a common hall, with doors or gates big enough to completely block the hall when opened outward. This makes it easy to separate species by driving the whole herd down the hall and simply opening and closing gates to make each critter go where it’s supposed to go. Then you can separate animals by species, even separate kids and calves from their mothers, without having to drag them or entice them with grain or treats.

![Diagram of a barn layout](image)

“For example, suppose you have a horse, a cow, and a few goats. The dominant animal, usually the horse, will go into the barn first, followed, perhaps, by the goats and the cow. You open the door to the horse stall so it blocks the hall, and beyond it, you open the gate to the goat pen. Then you open the main barn door at the end of the hall, and all the animals enter in order. Close the barn door before the cow enters. The horse will go right into its stall. Close the horse stall door, and the goats have nowhere else to go but into their pen. You can open the cow pen gate and the main barn door and drive the cow right into its stall.”

**For Goats.** Don: “The same principle applies when building a milk parlor for goats. To eliminate the hassle of trying to get only 1 goat at a time into the parlor, build it with 2 doors—one for the goats to enter the parlor by and another for them to leave by. These work best if they are goat-sized, in which case you’ll need another, larger door for you. The entrance door opens in while the exit door opens out, and both lock from the inside. With a setup like this, it’s easy to train the goats to come into the parlor one at a time and leave after they’ve been milked, especially if you feed them grain while milking and “free choice” hay afterward. The principle remains the same: allow the animal nowhere to go but where you want it to go, and you won’t have to ‘con-}
and bottom of the wall, and maybe even in the center, than screw vertical boards to the stringers. This is false economy, because it places the bottoms of the vertical boards where they are subject to rotting from the wet bedding. And you dare not use pressure-treated lumber in a stall, where the horse may be inclined to crib on it. It also places the center stringer right where a horse that is inclined to crib can best reach it."

For Cattle: Loafing Sheds. Don: "In many parts of the country, including the mountains of Colorado and the upper Midwest, it's quite common for cattle to sleep in three-sided, concrete-floored 'loafing sheds' and enter a barn only to be milked. The manure is scraped out by a tractor with a blade on the front or back; it is pushed into piles to compost or loaded directly into manure spreaders. In the milk parlor, the cow stalls are arranged so any manure or urine released during milking can be hosed easily into a manure channel and then out of the barn. I have even seen horses kept in loafing sheds quite successfully. Sheep are rarely kept in anything more substantial, except around lambing season. Goats and pigs need more protection although, in warmer climates, goats too can sleep in a loafing shed."

Design for Feed Handling. Don: "After handling of the stock themselves, the most important aspect of a barn to the animal keeper is ease of handling feed and manure. In the Midwest, most barns are built with an earthen ramp leading up to the hay mow, usually in the center of the barn. This makes it easy to back a truck up to the haymow and unload hay and other feeds, which can be pitched down to the animals on the lower story as needed. Often feeders are arranged so grain can also be fed directly from the hay mow. Similar patterns of barns can be found all over the country."

Feed Storage. Store hay up off the ground and with a roof, tarp, or plastic sheet to cover it. Openly available grain feeds attract rats and mice and can result in foundering. Most barns are designed with a separate room for feed storage. Inside that, make your storage containers or areas as rodent-proof as possible. Good possibilities are food-grade plastic cans or buckets, or metal drums that have never held poisons. And they must all have lids! Lacking a true lid, you can make do with a piece of flat, sturdy wood held down with a big rock.

You can also protect your stored livestock feed by making the habitat uninviting for rodents. Carefully clean up any spilled feed. Piles of lumber and junk are favorite nesting places for rodents, so try to keep those cleaned up and off the ground. Similarly, if your chicken houses, etc., are constructed up above the ground, you'll eliminate the dark, moist, sheltered spaces under them that rats enjoy. And a couple of big, tough mouser/ratter cats will help too. You can also set traps.

Design for Manure Handling. Every animal creates manure, and all their manure has to be dealt with regularly. How will you get the manure out? If you're working by hand, plan for a downhill run from the barn to the compost pile. Don: "It's okay to carry it uphill to the garden. Composted manure is much lighter than fresh, wet manure. Your best manure-handling system depends on the species of livestock, your method, and your intended use of it. Cattle produce copious amounts of manure, which is sloppy and must be shoveled, hosed, or scraped away frequently.

Horses produce drier manure but equally large amounts of urine, which must also be frequently dealt with. Goats and sheep produce small amounts of very dirty dry manure, which can be left to accumulate for a long time if they have sufficient clean bedding to sleep on. Pigs are very clean animals and will not drop manure in their bed area if there is room for them to walk 12 feet away from it upon arising."

See "Manure" in Chapter 2 for more!

Fencing

A basic fencing principle is to get it right the first time. Be sure and put the fence exactly on the line if you and your neighbors (talk to them first!) agree on where that is. They may even be willing to share costs or labor. Otherwise, put the fence at least a foot inside your boundary to save a legal hassle. Find out if there are any county restrictions on fences, such as setback rules or height limits. Make the fence strong enough. If animals get the idea that they can go through a fence, they're that much harder to keep in. In fact, once they've tested a fence and won, they're likely to ram their way through a fence that otherwise would have held them. Another basic principle is that the type of fence has to be tailored for the type of animal.

Don wrote me, "Fences can be used to fence animals in or out, to cross-fence pasture, to define spaces, for ornamental purposes, or even to use up rocks in a field. Construction of fences depends on their purpose and on the materials available. Common materials are barbed wire, woven wire, welded wire, electric wire, rails, slabs, milled lumber, stone, and combinations thereof. The overwhelming factor in deciding what type of stock fencing to build is the type of livestock to be fenced in or out. Cattle require very strong fences. Deer and goats need high fences; pigs and sheep, very tight ones. The old-timer's adage about building all fences 'horse-high, bull-strong, and pig-tight' applies only if you don't know what you're going to be keeping behind it, or if you have an unlimited source of labor and materials. It's far cheaper to build a 4-foot tall, 4-strand barbed wire fence for horses, a 4-foot high, 3-strand fence for cattle, a solid wood fence for goats, and a pen of welded 'hog panels' for pigs, for example, than to try to build one fence that will do for all of them."

Here's the rebuttal from William F. McCamman, president of New Zealand Fence Systems, a guy who sells fencing for a living. He makes a good point and wants you to always have the best (though he isn't giving any away). "That paragraph advocates building a fence for only the animals you know you will have rather than the full range you might expect. It is very expensive and laborious to raise a fence height later. A dime saved now might well cost a dollar later. Using barbed wire for horses is very short-term economy until the veterinary bills start accumulating. Fence designs vary due to topography, animal characteristics, pressure on the animal, consequences of failure, and the owner's mental satisfaction."

Fencing Books: For specific info on fencing for chickens, turkeys, goats, pigs, etc., see this book's sections about those animals. The latest and possibly greatest fencing book is Fences for Pasture and Garden by Gail Damerow (Garden Way, 1992), especially useful for goat people. Or see John Vivian's Building Fences from Wood, Stone, Metal, and Living Plants for complete how-to on every imaginable type of fence and hundreds of drawings and photos; Build It Better
Bull breaks the wire, there will be nothing to restrain your wire, though. If the juice is off for some reason, or a cow or cow, in recent years, especially for horses, but lately I’ve been hearding about some problems. This is a windy area, and it turns out the tape sheds in the wind and shorts the fence. The shorts are very difficult to locate since the tape may still look intact.”

For specific instructions on building and testing an electric fence, see Chapter 11.

Wire Fencing—Barbed and Woven: Don: “If you are not going to use electricity, you’ll do your cows a favor by using 9-gauge woven wire fencing. Cows sometimes develop the habit of scratching themselves on fence posts, and barbed wire can tear up their udders. It has even been known to entangle and kill horses. Woven fence with 12-inch wide rectangles is fine for cattle and horses but not for goats or sheep. They’ll get their heads stuck in the fence. Sheep are so dumb they may not think of pulling their heads back out, and they can starve to death! Goats will chew on the wire until it breaks and pokes holes in their cheeks. The experts recommend 6-inch mesh for goats and sheep.”

Posts: Don: “Posts of cattle fence absolutely must be the strongest you can afford. If you are using metal posts, use only the heavy-duty kind. They can be driven into most soils with a driver made by cutting the end off a truck driveshaft. The hollow shaft fits over the post, to be lifted up and slammed down repeatedly until the post is driven. Round wooden posts are not generally suitable for cattle. They are usually made from small-diameter trees, which have a high percentage of the soft heartwood. Use splits or other hard wood posts. Quartered sections of old telephone poles make adequate fence posts, though they have to be replaced after a few years.

“Just how long such posts will last depends mostly on how moist the ground is. In fairly dry soil, an untreated softwood post may last 3 to 5 years. The strongest wooden posts are triangular sections split from large diameter trees. Osage orange, black locust, catalpa, northern white cedar and red cedar will all last 20 years or more in average soil. In general, the softer the wood, the shorter the time it will last. Pressure-treated wooden fence posts, available in lumber yards or farm supply stores, cost about as much as metal posts but don’t last as long. They look nicer, though.”

Making Fence Posts. A “wedge” is a piece of metal shaped like an ax blade, flat on top—like a single-bladed ax head with no handle. Wedges are sharpened a little bit but not too much, because they tend to get stuck if they’re too sharp. You need at least 2 wedges to make fence posts (“splitting rails”). Cedar is the most popular wood to make wedges from because it is wonderfully easy to split and is slow to rot. Cedar is a nice wood in general; it has a good smell and a pretty appearance.

Pick a point on the side of the pole, up toward the “top.” Try to make that point a natural crack if there is one; there usually is in old wood. Tap the wedge in. Then drive it in with a sledgehammer as far as it will go. Take a second wedge and start driving it in where your pole still isn’t split apart farther down the line. That will loosen up the first wedge and put it at the farthest point of the split from the second wedge (you’re working your way from the top down). Keep going this way until you’ve finished splitting it.

Another way to get fence posts is to start by felling the tree; long, straight pines are good. You want regular posts to be about 3 or 4 inches across, so that’s what the diameter of your tree should be, because trees other than cedars don’t split well. After felling, cut them across to be the length you want. For uprights, the length should be high you...
want your fence to be plus how deep you want it to go in the ground. Corner posts need to be really husky: more than 4 inches in diameter is good. The poles to lay lengthwise can be longer.

Now you want to skin your pole. You smooth off all the knots and then strip away the bark. A flat-headed shovel is a good bark stripper. Hardwood doesn’t need a preservative treatment, but softwood does. That’s to keep bugs from lunching on it until your fence collapses in a heap of dust. So soak those poles for 2 months in a vat of used motor oil, and they’ll last longer than you will. If you haven’t got that kind of time, soak them in a mixture of pentachlorophenol and oil for a couple of days. If you have neither the time nor the money, use red fir, cedar, or black pine because they are the most rot-resistant. You’d get 15 years out of an untreated cedar post around here—less in a more southern or wetter climate. It also depends on soil acidities, and that gets complex.

**Stretching Wire:** Back to Don: “Wires can be stretched tight with a ratchet fence stretcher, available at farm and ranch supply stores, or even by tying or chaining them to a tractor or pickup truck. The idea is to grab onto the wire several inches before it reaches the corner post, so there will be enough slack wire to wrap around the post and twist around the tightened wire. Then go back and staple the wire loosely at each intermediate post. This supports the wire while allowing for future stretching and retightening. “Woven wire fences can be stretched the same way, but you may need to use a couple of fence stretchers together. One way is to wrap the end of the fence around a board or short post and then pull the post with fence stretchers, tractor, etc. After stapling the fence to the corner post, the horizontal wires of the excess fence can be cut free with pliers and wrapped around the post and themselves. Fence pliers are very handy for dealing with wire fencing, but very heavy wire cutters and a couple of claw hammers make an adequate substitute.”

**Bracing and Corner Posts.** Don: “Wire fences for horses and goats need wooden rails at the top, or the animals will break them down and just walk over them. And any kind of wire fence needs special bracing at the corner posts. These should be the stoutest posts you can get. Used railroad ties in good condition make good corner posts. They are treated against rot and can be purchased for $5-10. Stout as they are, they still need bracing. One way to do this is to brace the corner post on the diagonal with a short post notched into the top of the corner post. The other end of the brace can rest on a flat rock on the ground. A variation of this, which I think is stronger, is to place the first line post 4 to 6 feet away from the corner post and notch the bottom of the diagonal brace into the line post near the ground. A double strand of wire is then wrapped around the top of the line post and the bottom of the corner post. A stick is thrust between the two strands, twisted tight, and secured. Protect the tops of corner posts from rain and snow by tacking sheet metal flashing over the ends, or at least cut them at an angle, so water will run off.”

**Wire Fence Upkeep.** Don: “Since cattle like to rub against fence posts, the posts must be checked regularly and replaced when needed. A broken post can be jerked out of the ground by tying or chaining it to a horizontal post, which can then be used as a lever. Sagging wires can be tightened temporarily by crimping them into a zigzag with the claws of a hammer. Two framing hammers can be used to permanently tighten a strand of barbed wire. Hook the claws of one hammer over the line at one of the barbs, and use the handle as a lever to pull the wire tight, just like pulling a nail. While holding the wire tight with one hammer, use the other to pull the free end around the post and wrap it around the tightened strand.”

**Gates:** Don: “The simplest gate for a wire fence is one made as a freestanding panel of wire, secured to the gateposts with removable loops of wire. The gate can be stretched to a reasonable degree by making it just a bit too short to reach. The bottom of the gate endpost can still be hooked in the bottom wire loop by leaning the endpost at an angle. The top of the endpost can be pried toward the gatepost with a short stick and attached to the gatepost with a short length of wire. Even the shortest wooden gate is too heavy for normal hinges. The best kind of hinge for wooden gates is the kind that has a single metal loop on the gate and an L-shaped hinge pin that screws into the wooden gatepost. It’ll last forever, and you can easily compensate for sagging gates by lifting the gate off and screwing the pins in or out. Metal gates are light and strong, last forever, are readily available in many sizes, and cost plenty. You get what you pay for.”

**Wooden Fences:** Don: “Nothing beats wooden fences for keeping horses or goats. For horses, you need three or four 2 x 6 rails, equally spaced, with the top of the top rail 4 to 5 feet high, depending on the height of the horse. The top rail should be capped by a 2 x 8 rail laid horizontally, for strength. The horses will lean on it. Posts should be 8 inches in diameter or 6 x 6 square stock, every 8 feet. If
you're going to spend this kind of money on a wooden fence, it's silly not to buy pressure-treated posts and top rails. They'll have to weather for a year before you can paint them, though.

"That's the ideal fence for horses, but few horse owners can afford that kind of expense. Peeled poles 3 to 6 inches in diameter will do fine for fence rails, if they are inspected often. Lumber mills sometimes sell 'slabs' (the outside portion of the tree, with the bark still on) really cheap. They look 'rustic' and may be plenty strong. Watch for thin spots, though. Trees work really well as fence posts. Nail the rails to the inside side of the post or tree with 20d nylon-coated sinker nails."

**STONE WALLS:** Don: "Much of rural New England is divided up into picturesque fields surrounded by stone walls. The walls, for the most part, began simply as something to do with the stones that constantly surfaced in the fields. The farmers had to haul them to the edge of the fields anyway, and building walls there served as a boundary and used up the rocks without having to cart them further. If you are cursed with such a field, you might adopt the same plan for dealing with the stones. I can't honestly recommend any other good reason for building stone fences."

For more on stone fences, see “Fencing” in Chapter 8.

**FEED**

You'll either buy your animal feed or grow it. You can feed animals with live food that's growing in the field, such as pasture, or feed them from stored food such as hay and grain.

**About Forage Crops**

You can grow forage crops to feed animals in northern zones where you can't grow many fruits and vegetables. In practice, that means it's natural to eat a diet largely based on milk and meat (which your animals manufacture from the grass they eat) in the cold-climate places, where you can grow enough vegetable-type foods to keep you going. Cheat grass, which grows on rocky hillsides (and is thus useless for vegetable gardening), is that sort of forage crop; there are much better ones. But cows can eat cheat grass in the spring and get fat. (Goats get abscesses from it, though.)

A reader named Tom asked me if any special feed or type of pasture was necessary for animals. The feed question is really complex. I've tackled it in the section on each animal in this book. For the most chemical-free food possible, the best economy, and a good feeling of self-reliance and the adventure of it all, it's nice if you can raise as much of your own animal feed as possible (as long as you have unpolluted ground on which to do so). The old-timers raised food for their livestock as well as their kitchen, and so can you, although some feed companies do their dangdest to discourage you from doing so, for obvious reasons. Animals raised on home-grown feed typically gain weight a little more slowly and give fewer eggs and less milk. This doesn't mean you're an abusive owner. It means you aren't pushing production to the max as a factory farmer would. The value you gain in self-sufficiency, reduction in cost, and healthiness of your product can more than outweigh that extra production.

For more info on forage crops, see Richard Langer's *Grow It!* (1973) and D.A. Miller's *Forage Crops* (1984).

**VEGETABLE FEEDS:** The old-timers extended the forage season in pasture by planting special crops that the animals would harvest themselves in the fall, when the grass started dying back, or that the farmers could feed to confined animals during the winter. In fact, the following foods, together with hay, were generally used where grain is now used in animals' winter diet: sugar and mangle beets (the mangle, or "mangle wurzel," also known as the "stock beet," is a very large, nourishing beet), marrowstem kale, thousand-headed kale, turnip, rutabaga, carrot, forage radish, Swiss chard, Jerusalem artichoke, comfrey, beets, kohlrabi, and parsnips. These should be fed in combination with hay.

If root vegetables are to be your animals' basic winter feed, plan to supply about 40 lb. per day to a milking cow, 3-4 lb. per day to a sheep. But the best diet is a combination of various vegetables and hay, since too much of one thing in the vegetable line, especially beets, can be bad for animals—even make them sick. Horses winter better on carrots than on beets, and most animals do better on turnips, carrots, etc., than on beets. You can feed root vegetables whole to pigs (though they like them best cut and cooked), but you should cut them into pieces (or even grate or pulp them) for other animals. Fresh beets tend to cause diarrhea, so store your crop at least 4 weeks before feeding and then ease into this diet. Never feed moldy or partly decayed roots!

**About Ruminants:** Of the common domestic animals, the cow, sheep, and goat are "ruminants." A ruminant is specially adapted to eat much food quickly and then go elsewhere to digest it. And it is an animal inside an animal, because it digests food in a private fermentation vat where microscopic beasties transform the food so that the ruminant can digest the cellulose. Every ruminant is alive because it's in lifelong symbiosis with the tiny digesters in its rumen.

**Pasture**

Ruminants are capable of being nourished by grasses, leaves, etc. Pasture is a perennial grass crop, probably the most important use for grass. Tree crops and pasture are the two most underrated and overlooked ways to use land. Yet, compared to urban development and tilled soil, they are the two that are most protective of the soil and the environment. They both prevent erosion and enrich the soil.

Livestock growing on grass is a beautiful example of sustainable agriculture. The grass nourishes the animals. The parts of their feed that they can't use are excreted in a form that actually nourishes the grass, which uses the livestock's manure to help make more forage—and so on, year after year.

In the fall in more northern climates, the grass dies back and, during the months of winter, hay has to be fed. When spring comes, the grass grows again, the hay-feeding season ends, and the grazers can feast on that green stuff and get fat. But every pasture is different, and some are worse than others. Making a good pasture from a bad one or even from bare ground takes some effort. And it takes good management to maintain a proper animal/grass balance in order to avoid overgrazing and thus causing holes in that protective grass cover.

**GRASS MAGAZINES & BOOKS:** Here's the competition to factory farming techniques! *Graze* is a monthly publication with articles from and about graziers on pastured dairy, beef, sheep, hogs, and poultry. Subscription is $30/yr; $54
Another magazine focused on pasturing is The Stockman Grass Farmer, a monthly devoted to the art and science of turning grass into cash. It costs $28/yr; $50 for 2 yrs. To subscribe, or for a free sample, contact: 800-748-9808; 282 Commerce Park Dr., Ridgeland, MS 39158; sgsample@aol.com; www.stockmangrassfarmer.com. They also sell great books with titles like Pasture Profit$ with Stocker Cattle; Grass Farmers; Quality Pasture: How to Create It, Manage It, and Profit from It; and Paddock Shift: Changing Views on Grassland Farming. Those are all by Allan Nation, founder (1975) and guiding hand at The Stockman Grass Farmer.

Other good grass books are Rebecca Lewis's Making Pastures Produce (Rodale Press, 1980); Grass Productivity, by Andre Voison (1988); Why Grassed Is Best! by Jo Robinson (206-463-4156; www.eatwild.com/); and Holistic Resource Management, by Alan Savory. David Schafer's new book, Just the Greatest Life, is available from him at 760 SW 55th Ave., Jamesport, MO 64648; sales@schaferfarmsnaturalmeats.com; www.schaferfarmsnaturalmeats.com/ (He also sells natural beef, lamb, chicken, and pork.)

**Seeding Pasture:** If there's nothing left out there but brush and weeds, plow it up and replant to a good pasture mix of grains, grasses, and legumes. If there's something there but not enough, or if your land is hilly, don't plow it up to plant; just add new growth. To do that, plant in early spring, when the most bare ground is exposed. Go over it with a shallow-set disk and then broadcast seed, use a no-till drill, or just toss the seed out there in the spring, when raindrops have already softened the ground and future rain will splash soil over the seed to cover it.

**Pasture Seed Mixes.** The most nourishing pasture should include legumes (clover, alfalfa, lespedeza) because grasses don't provide as much protein and sugars for the animals. Pasture needs a soil pH of 6.5–7.0 and some nitrogen to thrive. Usually folks plant a mixture: a few grasses, a few legumes. Usually a few kinds of weeds are in there too, and that can be a good thing, since the more kinds of plants in your pasture, as long as they aren't poisonous, the better balanced in vitamins and minerals your animals' diet will be. It is possible to seed in some additional desirable plants for a pasture without actually tilling up and reseeding the entire thing.

Choose very hardy plants that are well suited to your area's soil and climate conditions. Drive around and look for a beautiful pasture. Then ask the owner what's in it. It'll probably have some grasses and some legumes (clovers). Bird's foot trefoil is a good combo livestock pasture plant and ground cover because animals can graze it to the bottom, but it always comes back. Good legumes are vetch, saffoin, peas, trefoil, alfalfa, and the clovers—red clover, white Dutch clover, yellow sweet clover, and subterranean clover (or "subclover"). Legumes, of course, build up the soil at the same time as they provide protein-rich food for the animals. Some farmers rotate periodically between grass and legumes, plowing up grass and planting legumes every 3 to 5 years for a hay crop or green manure, and then turning to a grass mix meant for years of pasturing. But Luane prefers a closely managed permanent pasture for economy and topsoil retention.

**Of Water and Pasture:** This last spring we planted 50 acres to a combination of peas and oats. We mixed the pea and oat seed and planted it together. We were raising the mixture to be winter feed for the cows and chickens. Well, there was a terrible drought, and most of it never germinated. In August we were having to feed our cows hay to keep them alive because there was no grass. It literally didn't rain one drop all summer. The price of hay shot up from the normal $45 per ton to $80 and more per ton. When the rains came at last, in the fall, the field finally turned green. The seed hadn't died; it had just waited. But December is no time to make hay. You have to get your forage planted before the good spring rains have stopped coming and hope there will be enough summer rains to finish the job. Or irrigate.

**Harvesting Pasture:** Grass needs to be mowed occasionally for best health, but your grass-eating animals will accomplish that without any effort on your part. They'll also fertilize the pasture for you. Ideal pasture harvesting is done consciously and carefully: it's a planned, intensive grazing that maximizes your crop's forage-producing ability. Grass is the cheapest feed for animals that can live on it. Making the most of your grass as feed can mean the difference between an operation that goes broke and one that makes a profit. Expert grass farmers use controlled rotational grazing, which means they have their grassland divided into smaller paddocks of as little as 1½–3 acres, usually by electric fencing. Stock growers using rotational grazing keep a close eye on the grass height and frequently change their stock from one paddock to another as often as every day. (This also reduces or eliminates having to search for lost animals.) An experienced animal owner can pretty much look at the grass in a paddock and know how long and how well it's going to feed the animals. Move the animals after the grass is eaten but before it is overgrazed and its comeback ability is damaged.

**NOTE:** Pasture plants are most nourishing for the animal when they're fresh and green. That means spring pasture—or pasture that hasn't been grazed for a while, has gotten water, and has had a chance to renew itself.

Regular shifting of animals plus a relatively short grazing period maximizes the ability of grass to come back and make more. Grass needs to be left alone to grow for at least a month after having been grazed down. This is time enough for the root system to recover its health and be able to store enough food to be able to grow back quickly from yet another livestock feeding. Grass with healthy roots grows, on the average, 1½ inch per day. But if you let the animals keep it too short, the roots lose their recovery ability and can't manage that maximum rate of growth any more. As a stock grower, that costs you money because then your land is no longer producing the maximum amount of forage, and your animals can put on only as much weight as...
the amount of food they can get.

The number of animals has to be suited to the amount of grass. In a drought, you'll have to sell some grass eaters, because your pasture won't be able to feed as many as usual.

Another way to get the most from your pasture grass is to use more than one tier of grass eaters: use animals that clip it closer to follow animals that eat just the top. But don't let the grass get eaten down so close that its ability to recover is harmed. A third method is to keep the animals out foraging in the pasture as late in the year as possible before resorting to hay feeding. It might surprise you how long the grass and animals can keep each other going.

**Pasturing Green Hay.** Alfalfa is even better pasture for cows than grass if you can spare it for them. But don't start animals on alfalfa if they aren't used to it; they'll bloat. Wet alfalfa is the most dangerous of all! We've got that situation now: a whole field of wet—soaking wet for 3 weeks—alfalfa with a layer of bleached hay on top of it. My husband Mike says we'll just give up and turn the animals in there. But they aren't used to alfalfa—to say nothing of wet alfalfa. So first we must wait until it dries off. And then we'll let them in there for an hour, and for a couple of hours the next day, and so on until they get used to it. And we'll buy hay from somebody who had better luck with this winter's feed. If very many people had the kind of weather we did in haying time, the price of hay will be up this fall!

**Hay**

"Hay" means a harvest of grasses (carbonaceous hay) or legumes—such as alfalfa, clover, or peas. Hay is dried plant food, preserved to serve as a winter food supply for herbivores.

**Winter Feeding:** To winter an animal, you'll need a certain amount of food stored: the kind of food that's right for each animal, or a combination of such foods, and enough of it. For grass-eaters, "winter" means the number of days that the ground is covered with snow or that, for some other reason, there is no grass. But a summer drought may dry up all the grass and have you feeding hay in summer too, long before the snow comes. Or your pasture may be too small to supply enough grass for the number of animals you have. In that case, you'll have to supplement with hay even in summer.

**Hay Plants:** Plants are grown specifically to be cut and dried for hay. Red and white clover and timothy (both brought over by pioneers from Europe) were old-time hay crops. Those are still valuable, but now there are other good hay species. The best hay is green, with leaves on the stems. This green, leafy hay is great feed for any herbivore. Just what you grow (or buy) for hay depends... Here are some possibilities.

**Legume Hay.** Best-quality legume hay is 12–14 percent protein. Possible plants to grow for legume hay are alfalfa, clover, lespedeza, peas, and vetch. The pioneers planted hay by scattering hay chaff as well as barn and haymow sweepings. Now you plant it by buying seed. You plant red clover or sweet clover at 10 lb. per acre. Weight per bushel of both is 60 lb. Ladino clover and white clover are planted at 2 lb. per acre but also weigh 60 lb. per bushel. But the most popular legume hay of all is alfalfa.

You don't need a big farm to grow good, high-protein alfalfa hay for your animals' winter feed. You can grow clover or alfalfa in your yard, as a garden rotation, or on a couple of spare acres. Just cut and dry well, and store under cover.

Plant alfalfa at 15 lb. per acre; weight per bushel is 60 lb. Here's my friend Stephen Scott on growing alfalfa for part of his pigs' feed: "If you plant a legume, you will be providing your pigs with protein. Protein supplements are one of the more expensive parts of your balanced ration, so if you plant some legumes, you can eliminate the supplements. Alfalfa is a legume—capable of fixing nitrogen from the air. Nitrogen is the critical building block for the production of proteins."

I have an Esmay seeder that I picked up from a rummage sale for 25 bucks. It is a push-type seed planter. It has an aluminum frame, two plastic wheels, and a little hopper for the seeds. You can get one from most seed catalogues, but they are quite expensive there. If you plant a very big garden it may well be worth the price, as it works well on almost all types of garden seeds.

I plant alfalfa in early May, after I have worked the ground well. I plant it in rows about 10 inches apart. When it starts to come up, I go between the rows with my old high-wheel cultivator. Alfalfa grows slowly; it would be overwhelmed by the weeds if I didn't cultivate. Just for good measure I go through the patch a few times a year as needed and pull weeds in the rows. If weeds are a problem in your fence, you can broadcast the alfalfa seed and rake it in with a garden rake. You will need about half a pound per 1,000 square feet. You can buy small amounts of legume seeds from garden seed catalogs, but you can save money by buying the seed from places that sell whole bags of it to farmers. Usually they will have an open bag from which they will be glad to sell you a couple of pounds. The very best alfalfa seed goes for about 4 bucks a pound from a farm seed store; it will be about twice as much from the seed catalogs.

I plant alfalfa in the field that the pigs will not be in during the year that I plant it. That is the case because the alfalfa plant will not be established and ready to provide much protein in the first year. It gets itself started and mainly grows the root system that it will need in order to provide grazing in the next year. If you have only 1 field,
then alfalfa will not work for you [as a rotation forage crop for pigs]. But you can still harvest to feed to animals.

**Grass Hay:** "Carbonaceous" hay means grass—not legume—hay. Native grasses provide good pasture but ordinarily do not grow luxuriantly enough to make good hay for winter feed. They also tend to be low in protein compared to legume hays. The best carbonaceous hay plants are probably bluegrass, oats, sudan grass, timothy—and any grass grain. If fed to animals, these hays always need a grain supplement.

**Grain Stubble.** You can cut (or pasture) the straw stubble that is left after grain crops are harvested. It can be part of your winter feed for big animals. The straw provides roughage, which they need, but you'll have to supplement it with better feed because straw doesn't have protein, which they also need. If the grain is harvested with the seed heads on, and before the straw is all bleached out, it's a different situation.

**Oat and Pea Hay.** This is a mixed legume and grass (including grain!) hay. For winter hay we use part alfalfa and part oat and pea seed and then cut it for hay when it's grown up. It's very nourishing for the animals, and I like it because it has grain right in there for the cows and chickens. This year the chickens got in there and scratched around for their own grain all winter long and did fine. I didn't feed them this winter except for that, and they're giving me 15 eggs a day now, plus the ones being set on. Harvest mixed oats and peas just as the oats start to turn. If you wait longer, the oats will be too ripe and won't make good hay. Peas and oats are good protein, and the pea vines and oat straw are good roughage.

**Making Hay:** There isn't anything complicated to it: you make hay while the sun shines. Hay is just dried grass or other green leafy stuff that is food for animals. But it's really vital to have, because with hay you can keep your cows, goats, sheep, rabbits, horses—and chickens, too, if the hay contains some grain heads—alive through the winter. And the animals will be making milk, meat, and eggs for you during the time when vegetables and fruit don't grow. You can cut any grass for hay; in time of terrible drought, I've seen an enterprising farmer down the Potlatch River harvest as many as 5 cuttings of hay off a single field. In irrigated country in California, where they grow hay year-round, they can get 10 crops. It takes both moisture and heat to make hay.

**Mowing.** When you know there's a lengthy spell of hot, dry weather coming up and your hay crop is tall enough to be worth cutting, you come through with a scythe (see "Mowing" in Chapter 3 for details) for small amounts of hay or a tractor-driven mower for a big field. Or you can mow hay with a horse-drawn mower. To scythe the hay, the old-timers had a special kind of cradle that put the hay in a windrow, which is a long pile of hay for drying. Their scythe was a steel blade mounted on a crooked stick. (Frequently sharpen the blade—that razor edge is important! And get rid of stones in the field so they don't ruin the blade.) In general, to put up more than an acre of hay, you'll be glad for a tractor-driven mower and a rake.

Here at Kendrick, Idaho, on unirrigated land, 2 hay crops is a good year. On irrigated land here in the river valley with plenty of good hot sunshine, I've seen an enterprising farmer down the Potlatch River harvest as many as 5 cuttings of hay off a single field. In irrigated country in California, where they grow hay year-round, they can get 10 crops. It takes both moisture and heat to make hay.

**Raking.** The cut plants are then left lying right where they have fallen. Or the cut hay can be gathered using a horse-drawn dump rake, which then dumps it in a windrow. Or it can be forked by hand up into piles or rows by hand to dry. It cures in the sunshine until nearly dry. Then you come back and, by hand or by machine-pulled equipment, rake the hay into windrows.

**Drying in the Field.** You let the hay lie in the sun for a few days until it has dried out (it doesn't have to be all bone-dry). You probably haven't got it safely dry yet if you twist a wisp of hay and it feels tough, if you break a stem and it feels tough, if you break a stem and there is evidence of moisture, or if you can scrape the epidermis off a stem with your fingernail. It is probably cured enough when the hay is acting sort of brittle, and there's no wetness when you twist a stem, and the epidermis doesn't peel off the stem when you scrape it with your fingernail. Then gather it up and get it under cover.

From the time you cut it until the time you can get it under cover, you pray that it won't rain. If it rains all the time, you can't harvest hay. You want rain when the stuff is growing, but when you are ready to harvest, you want sunshine. If you have good hot sunshine, you should be able to get your hay cut and out of the field in 4 days. Then it can rain again, and you'll be glad because that gets your next crop started growing. If you're rich and can afford a
swath, you can harvest hay even more quickly. You could swath on a Monday and, if it's hot, you could bale on Wednesday.

The reason I'm moved to make these remarks is because this summer it has rained practically 3 weeks in a row (we normally have hot, dry summers), and our first hay cutting is ruined. If hay is cut and then lies on the ground in the rain (and you can't finish harvesting if it is wet), the rain washes out the color and a significant amount of food value. You'll have to wait again for it to dry out, and it'll take longer this time because it's lying in a mass on the ground. Instead of being nice and green, it then looks yellow like straw. Such hay is called "bleached," and it's no good. Even so, you've got to get it up off the field so the grass can grow back again. If you left it lying there, it would act like a mulch and stifle the plants underneath. So now we've got that bleached hay to get rid of—whenever it dries out enough so we can get into the field and work.

**MOVING HAY:** The old-timers, after raking hay into windrows and curing it, loaded it with a pitchfork from the windrow into a wagon—literally "pitched" it up there—for moving to an outdoor haystack or indoor storage in the barn's haymow. Then they pitched the hay from the wagon into a big net that hung from a rope on the end of a derrick. Then they turned the derrick around and pitched it from the net into the haymow.

**Baling.** Baled hay is so much less work to move than loose hay. For a large field, you must consider hiring somebody with a baler to come and bale it. A baler picks up the cured hay from the windrows, presses it into a rectangular block, and ties the block firmly together with wire or twine. Those bales then are dropped in the field. You'll have to come back to pick them up, load them onto something, haul them somewhere, and stack them there. There's a newer type of hay baler that rolls the hay into huge, heavy, round bales that are like mini-haystacks in themselves, each weighing about a ton. The stacks can be left in the field and used as feed right where they lie.

**Hay Hooks.** These are invaluable at haying time if you're working with 50-100-lb. bales. I've used them on untold hundreds, ever since I was a little girl. You'll soon get the knack of slipping that hook into the bale and lifting the bale wherever you want it, bracing the other end of the bale against your body.

**STORING HAY:** Gather up your dried loose or baled hay and pile it to make an outdoor haystack, or move it to the haymow of your barn. But be sure it's dry.

**Of Damp Hay and Fire.** Another reason for wanting your hay dry before you bring it in is that damp hay has a little trick of setting itself (and your barn) on fire by spontaneous combustion in a composting heat-up. Hay has this tendency if it is piled up in storage incompletely cured—that is, too wet. I know it doesn't make any sense that damp hay is more likely to catch on fire than dry hay, but it's true—heavy, leafy legume hays are more likely to do that to you than is grass hay. Stacked hay (or unthreshed grain) makes heat in its early stages of curing.

To get an idea of how hot your stored hay is, push a 4-foot wooden stake deep into the stack but still reachable from outside. Leave for a while. Then suddenly pull it out and feel the inner end of it. That will give you a sense of the temperature.

**Bale Storage.** For bales out in the open, use sturdy plastic or tarp; tie it firmly down so it doesn't blow away. Unprotected hay is likely to mold. To get the bales off the ground, stack them on crisscrossed boards to allow some air circulation under the bales.

**Making a Haystack.** Haul the hay from your field to the place where you're going to build your stack. Now create a haystack that is at least 12 feet tall, with a diameter at the base of around 14 feet or more. The general shape is round at the base and as conical as possible at the top. The idea is to build a pile so dense and so conical in shape that although the outer layer will probably be ruined by weathering, from a few inches on in, the hay will stay green and delicious for your livestock.

**FEEDING HAY:** The best hay for horses is what's left over after you've fed the other animals, like cows and goats and rabbits. That's because horses can get by with almost anything, but the others can't. Horses even like timothy hay. But don't give them moldy hay; that gives them a condition called "heavey horse." Milk cows won't hold up so well on grass hay, and goats and rabbits need good green alfalfa. Hay gives cows 2 important foodstuffs, protein and roughage. Protein feeds them, and there's lots of protein in alfalfa and pea hays (not so much in clover hay). And they need roughage, provided by the grasses or stalks, to make their systems work right. Alfalfa hay is good hay because it has both. If you're feeding a low-protein hay like clover or grass, then you need to supplement that feed with grain to supply the needed protein.

**Silage**

Crops for forage (livestock feed) are preserved by either drying (hay) or ensiling (silage). I'll take a time-out here to tell you how to salvage a crop that will never get dry by making it into silage. There are parts of the country where during many years, grains never get dry enough in the field for normal curing. There are occasional years in other areas where that happens too. If it does, the grain can't be saved for people food, but it can be salvaged for livestock feed by a natural fermentation (and preservation) process called "ensiling." Grain silage is a sort of hay-based sauerkraut. It will smell awful and be a disgusting brown color. And your animals will love it and survive the winter on it.

**Making Silage:** Start with any moist green plants: grains, grasses, legumes, hay mixtures... But not too moist. To reach the ideal dampness for a non-corn silage, wait to harvest until the leaves and stems are wilted and limp-looking. You can make it from any or all parts of the plant—including the roots, if you want to take the trouble to pull them out. To make good silage, the green stuff must be well compacted and stored in a dark, confined, airtight container. Under those circumstances, it undergoes fermentation, creating organic acids that preserve the silage as long as the container is airtight.

**Chop.** To speed the compacting and fermenting, chop or grind the plants. Inch-long sections are ideal. You're making salad for animals.

**Moisture.** If the chop is too dry, you need to add water to produce the bacterial fermentation. But usually the plants are plenty moist, unless they've been harvested after a frost. If corn is let dry on the cob, right on the plant, and then the whole thing is dried, pulled up, bundled, and made into...
because that's one thing silage is comparatively short on.

Too much moisture is also a problem. Too much water can cause a partial failure of the preserving process, yielding bad-smelling, poor-quality silage. At worst, there must be a hole in the bottom of the sack or a drain in the bottom of the silo to allow excess liquid to run out. For good silage, the greens or grains need to be damp but not submerged in liquid. If you drain, then close the hole to keep out air.

Airtight Storage. To make small-scale silage, pour that chop into plastic sacks, packed in as tightly as possible. For large-scale silage, you put the chop into a giant plastic bag that looks like a huge sausage casing or into a special building made of hollow tile, concrete blocks, or reinforced concrete, or into a glass-lined steel cylinder called a "silo." To make large-scale silage without the special building, you can use a trench or pit in the ground called a "pit silo." Simply bulldoze a ditch, put the silage in there, and pack it down as tight as possible. If there's no cover, the top foot will spoil. It helps to cover any silage pile with plastic.

The fermentation process that preserves this feed will occur only if all the oxygen is used up by the fermentation process and no more oxygen can get in. So when packing, avoid air pockets and pack as tightly as possible. The silage will pack tighter if you pack a large amount over several days, giving each layer time to wilt and settle before you add another one. If air gets in, an equivalent amount of the silage will be spoiled. (You can still use spoiled silage as organic manure.)

CAUTION: The gases that accumulate in a silo can be fatal to breathe. Operate the blower for a few minutes to remove them before entering the silo.

FEEDING SILAGE: Silage that contains grain is a more nourishing feed than silage that doesn't. Supplement a silage diet with some form of protein (a dairy product, good alfalfa hay, commercial protein concentrate, or some such), because that's one thing silage is comparatively short on.

Of Grain and Grain Sprouts as Food. All the grains are good food for both human and beast, although some need to be husked or ground for better digestibility. Baby poultry need small cracked grain at first, like what you could make in your blender, but they can manage larger grains within a few weeks. A livestock feed of half wheat and half corn is great. All the grains will sprout. The best of the old-time farmers regularly fed some sprouted grain to all their livestock in wintertime. Do that and you won't need to use "all-vitamins-included" commercial feeds! (See Chapter 2 for more on sprouting.)

Animal Feeds You Buy
For every animal you are feeding, you can go one of three routes:

- Go to a feed store and buy pre-mixed rations.
- Go to a feed store and buy foods that you have them mix, or mix yourself, to the formula of your personal choice.
- Raise your own feeds for your animals, making your own choices about what to grow and what proportions to feed it in.

FEED MILL FEEDS: The good thing about these feeds is that they are assembled according to formulas devised by expert animal nutritionists, and all feed elements the animals could possibly need are present in ample amount. The bad news is that although people doctors and, yes, animal doctors too must write a prescription if they want to administer drugs, feed mills have no similar restrictions. Thus animal feed companies can put into the feed whatever antibiotics or other drugs they choose, in whatever amount they choose. There is no supervision of what they put in. They have a huge loophole, and they use it.

Because animal antibiotics and people antibiotics are exactly the same drugs, this is a serious problem. Every factory farm that is feeding antibiotic-laced feeds year in and year out is potentially breeding yet another antibiotic-resistant supermicrobe. These bugs then can sicken humans, for all too many human diseases have started by crossing over from animals (most recently, the AIDS virus), and this potential will always be there. Low-level, permanent antibiotic drugs are most commonly used (as of 1993) in the feeds for poultry and for feed-lot cattle (not cows/calves on grass). Drugs are used not only because they keep the cows well but also very much because animals on an antibiotic diet grow faster and larger. That side effect makes feeding antibiotics profitable to the grower.

But I think that antibiotics should never be given to animals as a routine lifelong or long-term dietary supplement. Instead the animals should be raised with such a nourishing diet and healthy environment that they are able to naturally resist disease. And farmers should do without the extra growth caused by the antibiotics. If such an animal actually does get sick, it could be treated; if there is a risk of transmission of the illness to the herd, the animal could be briefly given a preventive treatment. But that's it.

Just recently [1993] a U.S. senator introduced a bill calling for regulation of the feed mills' practice of adding drugs to animal feeds. It didn't pass. He'll try again. This is much-needed legislation. I hope he receives more support next time!

FEEDS GROUND TO ORDER: With these, you buy the feed ingredients you want and have them mixed and ground to order. This way you can include what you want — and omit what you don't want. Shawn Trumble of Ionia, MI, wrote me, "We try to stay as far away from chemicals as possible. The feed store can never understand why we have our feed ground with no antibiotics or other strange stuff in it! We do, however, vaccinate for everything we can. We figure we're money ahead!"
Growers who are striving to produce certified organic meats are now looking for organic livestock feed suppliers. They need grains that are organically grown in their feed mixes with no antibiotics, growth promoters, or hormones of any type. ATTRA's list of such feed suppliers is at www.attra.ncat.org/attra-pub/livestockfeed.html. You can find another list of organic feed suppliers worldwide at www.dba-sw.com/ppoultry/osuppliers.html. For example...

Buckwheat Growers have a farmer-owned cooperative that grinds and mixes alternative grains as feed for livestock: 218-631-9212; 218-445-5475; 206 Aldrich Ave., PO Box 492, Wadena, MN 56482; www.buckwheatgrowers.com.

Modesto Milling: 209-523-9167; Modesto, CA.

Organic Unlimited is a NOFA-NJ certified feed mill: 610-593-2995; fax 610-593-2155; PO Box 238, Atglen, PA 19310; www.organicunlimited.com.

Valley Ranchers: 800-354-4503; eggscvr@pacbell.net; Arcadia, CA.

Willow Brook Feeds, 707-795-7190; PO Box 750818, Petaluma, CA 94999.

ANIMAL DOCTORING

Ask neighbors or your vet what diseases are prevalent in your area so you can take preventive measures or be on the lookout for the ailments. Keep your animals well by providing good living conditions, giving whatever immunization shots are needed in your area, and checking on them daily.

SOURCES OF MAIL-ORDER MEDICINES AND SUPPLIES

Jeffers Vet Supply: 205-793-6257; 800-633-7592; Box 100, Dothan, AL 36302.

Nasco Farm and Ranch offers general equipment, including dairy and A-l supplies: 920-563-2446; 800-558-9595; fax 920-563-8296; 901 Janesville Ave., Ft. Atkinson, WI 53538; www.nascofa.com.

Omaha Vaccine Co. offers everything for pets (dogs, cats, birds), and for horses and large animals (not just vaccines); 800-367-4444; fax 800-242-9447; Box 7228, Omaha, NE 68107; www.omahavaccine.com.

UPCO sells pet supplies of all kinds andworms for some farm animals. Free 200-pg catalog: orders 800-254-8726; fax 816-233-9696; inquiries 816-233-8800; PO Box 969 (3705 Pearl St.), St. Joseph, MO 64502; sales@upco.com; www.upco.com.

Valley Vet Supply offers wormers, calving supplies, sheep and pet supplies. Your choice of the 72-pg free Equine (horse), Pet, or Farm and Ranch catalogs: 785-562-2484; 800-468-0059; PO Box 504, Marysville, KS 66508; 1118 Pony Express Hwy (East Hwy 36);

Wiggins & Associates offer 3,000+ items of international vet and animal care supplies: 503-667-0716; fax 503-667-4701; 800-600-0716; 503 SW Victoria Court, Gresham, OR 97080-9265; jpwiggins@att.net; www.wigginsinc.com.

HOME VETTING BOOKS: Most books about livestock have a vetting section. Animal Husbandry and Veterinary Care, by Guy Lockwood, DVM, and The Merck Veterinary Manual, by Merck and Co. (1986), are especially useful. Handbook of Livestock Management Technic, by Battaglia and Mayrose (1981), covers procedures, not diseases, and is very professional, but usable by an amateur. Rural Bookstores carries Cattle Lameness & Hoof Care by Roger Blowy; Horse Foot Care, by Doug Butler; How to Be Your Own Veterinarian (Sometimes), by Ruth B. James, DVM, The Lame Horse, by James R. Rooney, DVM, etc.: 931-268-0655; fax 931-268-5884; ruralheritage.com. Keeping Livestock Healthy (revised/updated 4th edition), by N. Bruce Haynes, DVM, focuses on prevention and covers nutrition, housing, and care, plus livestock disease and treatment (Storey Books, address in Chapter 1).

The Complete Herbal Handbook for Farm and Stable, by Juliette de Bairacli Levy, pioneered herbal veterinary medicine. First published in 1952, now a classic in its field, it has been revised, updated, and enlarged. The American Holistic Veterinary Medical Ass'n does "holistic veterinary medicine, acupuncture, chiropractic, herbal medicine, homeopathy, nutritional therapy & other complementary or alternative modalities." The website contains listings of manufacturers, practitioners, publications, suppliers, links, treatments, etc., none guaranteed: 410-569-0795; fax 410-569-2346; 2218 Old Emmorton Rd., Bel Air, MD 21015; www.AHVMA.org; or www.altvetmed.com.

Common Home Vetting Procedures

The most important is the daily lookover you give your animals. You get to know who they are and how they are. Then your observation and gut instinct will tell you when something isn't right.

GIVING SHOTS: Practically everybody who's any sort of a farmer gives his own shots. It is cheaper and more convenient. You can buy vaccines in bulk from vet suppliers that specialize in mail-order business to farmers. But it's better to buy from your own vet or vet supply center because of all the free advice you'll get with your purchase and the promptness with which you can get it home. Another disadvantage of mail-ordering vaccines is that there's no way to know in advance for sure who is going to be sick with what. You can also get needles, antibiotics, and immunizers from your vet or supplier.

Combicotic is a veterinary antibiotic that will store in
your refrigerator and is a good thing to have on hand, and it keeps for a few years anyway. Sick animals that need an antibiotic get shots—usually one a day for 3 days, or more if necessary—2½ to 3 cc. for a baby calf. Penicillin and its descendants are very precious stuff for man, beast, and even insect. (There's a variety of Terramycin in an edible powder that's for bees.) Boil your needles between uses. Plastic needles can be boiled too.

**Filling the Needle.** Peel off the little foil cover in the middle of the metal cap on the medicine bottle. That exposes a rubber area. Just force the needle point right through the middle of the rubber into the bottle. (Turn the bottle upside down.) Force the air out of your needle before you put it in the bottle by pushing the plunger clear down. Fill your needle with as much as you need, measuring by the calibrations on the body of the needle as you pull back on the plunger. (If you accidentally pull it all the way out, you have to start over.) Pull the needle back out of the bottle. Look at it to make sure that you don't have air in it. Squeeze a drop out of the end to make sure. Air inside a cow is unhealthy.

Bobbi McCollum, a Pietown, NM, nurse, wrote me, "When you pull medicine out of the bottle, do this first—draw plunger back to where you want to fill and inject an equal quantity of air into the bottle whose medicine you're removing. If you don't, you create a vacuum in the bottle. I assisted in a surgery of glass removal from a nurse who had had a bottle shatter in her face for just this reason."

Fill your needles on the site. Don't let children carry them with bare tips. I've had the experience of falling with a needle in my coat pocket. It rammed right into my innards. I was lucky it wasn't an eye. So get your animal ready first; then get the needle.

**Sticking.** Cows don't like shots any more than you do, and they have a lot more fight. Lock their head in a stanchion with the lure of some grain. Hobble or tie at least one hind foot very securely. With goats you can have someone sitting on the head and someone on the behind; same for a calf. If your cow isn't gentle and won't come into a stanchion, you need the kind of squeeze chute used for loading cows (a tight corridor that can be locked off in front of and behind the animal so it can't go anywhere). Or you will have to rear thigh. Don't stick into a bone. Aim that needle right in the middle of the muscle. You won't have to jab as hard as usual.

**FEEDING A PILL:** Cow pills seem huge. Here are the basics for giving pills to calf, cow, goat, or horse. For a calf, have somebody help you hold it. For a cow or goat, put it in the stanchion. A good horse should just stand there and accept anything, but you may need help. Push your fingers into the mouth, up at the corner where there are no teeth, and the animal will open up the teeth part. (You open a horse's mouth to put the bit in the same way if it won't just do it for you.)

Put one arm firmly around the neck and, with the hand you've got in its mouth, just push that big bolus pill right down the animal's throat hole as fast as you can. Don't worry about choking it. You won't. Don't worry about making it uncomfortable. If the animal is sick enough to need the pill, a moment's discomfort is unimportant. When you think the pill is shoved down far enough, pull your hand out and with both hands try to hold the animal's mouth shut.

**Bolus Gun.** From Lane Morgan: "In my wimpy opinion, you'd have to be nuts or desperate to give a cow a pill without a bolus gun. You stick the pill in the slot at the end of the plunger and then push it down the beast's throat. Use the nose holder to keep her head pointed up until the pill is swallowed. We've had 3 milk cows. Two have been Holstein/Hereford crosses—bigger and not as docile as our one sweet little Jersey. I could dose them myself with the bolus gun and nose holder. Without it I wouldn't want to try. If you have two people, you can substitute someone's fingers for the nose twitch."

**Down or Out?** Now the animal will try to get the pill up and spit it out. One of 3 things will happen. It will either swallow the pill. Or it willburp it up, chew a moment, swallow half of it back down (that's why you're holding the mouth shut), and spit out the other half when you finally let the mouth open. Or it will spit the whole thing out. If it spits out half or all, you simply have to start again and try to poke it down farther this time, over and over, until you finally get that pill down your animal. The usual beginner's problem is not poking it far enough down. That's one of the reasons that a bolus gun is so helpful.

**Electrolyte Dosing:** Lane Morgan says: "If you're raising a lot of calves, especially bought calves, I think it's worth it to buy the rig for dosing them with fluids. It has a bottle that you fill with your electrolyte solution or whatever and hang from something high. That's attached to a hose that you put down the critter's throat. The hose has a clamp so you can release the fluid when the time is right. All the parts are easy to sterilize and reuse. Of course, you could make your own. The point is to have something that works with minimum struggle and maximum cleanliness. I brought a far-gone scouring calf back from the brink with one of these, so I'm a believer. One saved animal will more than pay for it."

**Body Temperature:** Use a vet thermometer with a string or clip, or tie a string on a drugstore thermometer if you don't want to go in after it, because they tend to get sucked in! You put the thermometer up the animal's rectum, just like you do with a baby. A vet thermometer comes with an attachment so you don't lose it into the animal. Or use a baby thermometer with your version of the attachment.

The usual rectal temperature of a goat is 101–102°F. For a calf it's 98–102.5°F; for a cow it's 101.5°F, but can range from 100.4–102.8°F normally. Sheep temp is 100.9–103.8°F. A pig's is 101.6–103.6°F. Rabbits are nor-
Managing Livestock Reproduction

**Definitions**

- **Freshen:** To give birth and start milk production
- **Gestation:** Pregnancy
- **In heat, in season:** When the female is ovulating and will stand still to receive the male and get bred
- **Service (v.):** To breed an animal; to get her pregnant
- **Settled:** Pregnant and out of heat
- **Spring:** When the lips of the vulva swell, a sure sign that the birthing is coming
- **Udder:** Her “breast” milk bag

**Heat Periods:** A mare (female horse) stays in heat for 2–11 days, usually around 6, and comes in about every 22 days. She will be in heat again in 3–15 days after giving birth to a colt. A sow comes in heat again 1–8 weeks after pigging (which means to have a litter of babies). A ewe (female sheep) comes in heat for about 35 hours every 16 days. A lady dog will stay in heat for 9 days, more or less, and a cat can stay in even longer. After a large animal is bred and out of heat, she is said to be “settled.” She won’t feel that good again for a long time.

**Artificial Insemination (A-I):** A-I enables you to breed a cow when you can’t manage or don’t want to provide a bull. Instead, the cow is given bull semen through a video and out of heat; he or she will know for sure. Or take a course and learn to do it yourself!

**Gestation Period:** A “gestation period” means how long an animal is pregnant before giving birth. People take about 9 months. These periods vary somewhat, but in general, a cow will calve 285 days from her date of service, a goat will kid 151 days after, a sow will pig 112 to 113 days after, a ewe will lamb 150 to 152 days after, a dog has her litter 60 days after, and a cat has hers 64 days after. In other words, a mare (female sheep) comes in heat for about 35 hours every 16 days. A lady dog will stay in heat for 9 days, more or less, and a cat can stay in even longer. After a large animal is bred and out of heat, she is said to be “settled.” She won’t feel that good again for a long time.

**CARE OF NEWBORN’S Navel:** For the offspring of large mammals such as pigs, goats, sheep, and cows, the baby gets its navel cord coated inside and out after birth with iodine. There will be a few inches of cord hanging under the animal’s abdomen. An infection from germs that entered through the navel is prevented by grasping the baby firmly while it is lying on its side and dipping that end of the cord inside a bottle of iodine. Then tip the bottle up against the baby’s tummy so that some of the iodine runs up into the center of the cord. For best protection, this should be done within minutes after birth. To be safest, do it again 2 days later.

**Vaccinations:** This depends on the kind of animal and what diseases you have in your area. Ask a livestock-raising neighbor or a local vet. We give all our calves immunity shots. Much as I hate to stick a needle in anything (I really have to pray hard to get the courage), it’s better than seeing them sick.

Once I didn’t practice immunization of my children. After almost losing a child to whooping cough, I’ve totally changed my mind on that issue, and now my babies get shots against diphtheria, tetanus, and whooping cough (the famous DPTs); the oral medicine against polio; and the 3-in-1 against hard measles, German measles, and mumps just as soon as the doctor allows.

Now it makes me so upset to see advice in otherwise sensible and useful books and newsletters telling women that immunization is more risky than the disease. That’s totally false! And it makes me furious to read that for whooping cough, you’re supposed to give a “decoction of garlic and thyme” and “apply clay poultices on the back of the neck, wheat bran-climbing ivy poultices on the solar plexus,” etc. What baloney! Absolute, total baloney! I know these writers never had a child with whooping cough, or they’d have offered more realistic advice. How irresponsible of them to presume to give advice that’s not based on experience to trusting young mothers faced with the true risk of their child getting a desperately serious disease.

What you do for whooping cough is give up peace of mind and sleep. Your child of any age—infants can get this!—will have a literally life-threatening coughing attack, desperately battling to dislodge the constant dangerous buildup of the most thick, copious, ugly masses of phlegm you can imagine, every 8 to 18 minutes, day and night, for the next couple months—and longer. The child can drink light liquids like 7-Up. There won’t be much other eating or drinking. There will be constant vomiting, though you have to try to get food.
down. But milk curdles the phlegm and makes it worse. You have to be present for every coughing attack to get the child sitting up and leaning slightly forward so the exhausted victim can get the phlegm out of their mouth. Literally scoop and pull the long strings of phlegm out of the child's mouth with your fingers if the child is choking on them and is unable to get them out without help.

There is no medical treatment for whooping cough, even in these modern medical-wonder times, although perhaps intravenous feeding could help. Once the child has the disease, all you can do is practice unending vigilance and tender nursing until the next spring, when it will finally completely go away. You'll need somebody to bring you whatever you need because you'll have to stay constantly at home with the sick child until the disease has run its course. You cannot possibly leave even for a moment. It's extremely contagious, so you'll have to practice quarantine.

If a medical person knows your child has whooping cough, they will insist that the child be hospitalized, even though they have no treatment. With luck and faithful nursing, in or out of the hospital, your child will live. But not all do. The younger they are when they get it, the more risky it is for them.

Nor is measles a routine, harmless disease in the way that chicken pox is. Measles can have horrible results: brain damage, deafness, blindness, etc. Mumps can result in permanent male sterility. German measles can result in a dead or brain-damaged baby if you're pregnant at the time. When I was young, polio was the mysterious scourge of the immunization, which are something like 1 in a million. Nursing my 14-month-old baby Danny through whooping cough was one of the most terrifying, exhausting—and instructive!—experiences I ever went through.

The technology of immunization is not witchcraft. If this book could be long enough and you took time to get the lab tech training and could afford the lab equipment, you could be told how to make and administer vaccines. Pasteur invented the process way back in the 1800s and began saving lives right away, vaccinating against rabies and the scourge of smallpox.

Well, back to animal immunizations. Around here newborn calves get 2 cc. of vitamin A and D solution and 2 cc. of Bovine (the immunizer against white muscle disease) as soon as possible after they are born. At 3 months they each get 5 cc. of black leg vaccine.

**Teaching Bottle Drinking:** To give a bottle to a resistant kid or calf or other young mammal who doesn't know what it's supposed to do: Force its mouth open. Put in the nipple. Hold its body to prevent it from backing away from you. Once the nipple is in, hold your hand around the sides and bottom of its mouth to prevent it from spitting it out. Once it gets some swallows of good milk, it'll get the idea. Kid goats are easier to bottle-break than calves.

**Castration and Dehorning**  
**Reasons for Castration:** Castration is worth considering with sheep, pigs, or goats and almost unthinkable with calves and horses unless you specifically want to use a male for breeding. There are good reasons for castrating.

**Aggression.** The following section focuses on cows, but the same principles apply to other large species. (And if you think human males aren't aggressive, just read a history book—or the newspaper. Or study anthropology. One study of bones from a dig found that those of females had 25 percent more fractures than those of males. The conclusion was that the prehistoric ladies had suffered those injuries at the hands of their not-so-gentle men. Thank God we're more civilized now.)

Bulls have very reckless, aggressive instincts and the size to easily do harm. But even ram sheep and buck goats have hurt people. The male is said to be willing to risk itself at the slightest provocation. I got a letter only a couple of weeks ago from a friend homesteading in Mexico whose 8-year-old boy was run down by a Charolais bull that escaped from his pen. The boy's leg was broken. The list of animal owners who've been harmed, even killed, by uncut (not castrated) male animals is tragically long.

Bulls with horns are even more dangerous. Horns and testicles are no joke when your bull calves are in the alfalfa and you are trying to chase them out before they bloat themselves to death. The next thing you know they are taking the whole thing wrong and have decided to charge you.

The reason the word “steer”—the term for a castrated bull—has become practically synonymous with “beef” is because extra bulls are so hard to manage. Bulls, with horns or without, can be dangerous. They are more aggressive than cows, more likely to attack if they think they have been provoked. Bull calves grow big enough to become dangerous well before the age of butchering. Nature meant the bull to protect the herd from predators as well as to compete with other bulls for dominance in breeding.

Don't think that because milk cows are so gentle, milk-breed bulls will also be gentle. In fact, it is just the opposite. For some reason, the bulls with the worst disposition of all are those of the dairy breeds.

**Premature Breeding.** A bull calf (or a male of another species) is ready to breed well before he is ready to butcher. If bull calves would only mature to butchering size before they mature in sexual capability and aggressive instincts, this problem wouldn't exist. Unfortunately, when they are less than half-grown, they think and act like any full-grown bull. So if you have a lot of young bulls around, you are liable to get 5-month-old heifers bred.

If a heifer (a young female cow) gets bred too young, she is bound to have trouble in calving, possibly meaning a choice between her life and that of the calf, or even a dead calf. Even if she calves successfully, she may not be able to make much milk, and her full growth may be stunted by the premature calving. The same is true of other species.

**Fence Busting.** Cows are very strong and can go through fences if they want to badly enough. A bull—even a very young one—is a big, husky animal. They quickly reach sexual maturity, and the first time they smell a cow in heat it doesn't matter whether they've ever been near a cow before. The fact that there is a fence between the bull and the cow in heat is no more important to the bull than if it was 2 garden stakes with a string between them. He will be inclined to just walk through, over, or under the fence, scarcely showing bewilderment at why that thing happens to be there just then.

**Control of Herd Genetics.** Genetically speaking, you have a lot more control over what's happening in your herd.
if you are breeding only from known sires at known times. If you have a Jersey bull calf and your neighbor has registered Herefords, and your bull calf goes through the fence and breeds some of his cows, he is going to be just furious! And that is bound to happen if you are keeping bull calves anywhere but locked up in your barn or in a real tough corral. He would owe you the same consideration if your situations were reversed. Cattle ranchers, as a matter of routine, make steers out of all their bull calves except the few they mean to raise and keep or sell as breeding sires.

**HOW TO CASTRATE:** So you see, the alternative is worse than a brief surgery at a young age for male calves and young males of other species in which these problems are possible.

**Age When Castrated.** On big ranches, the calves get cut and branded and have their shots all at once when they are moved. The February calves go to spring pasture in April (more or less depending on where you live), and that's when they are handled. The fall calves are done when the animals are brought back to their winter feeding place. So the typical age is 6 to 8 weeks on a calf. It is important to do the castrating after the animal is well established but before it is too old. Don't castrate too late. I've heard of people who had 5 or 6 big yearling calves bleed to death because they were too old when it was done. A year is way too old.

Nowadays there are several different ways to castrate.

**With the Knife.** Castration by the knife is a technology that has been around a few thousand years. It is a bloody and disgusting business and the most traumatic for the animal. Cowmen did it at branding time. They branded, gave shots, and steered, and so got all that stuff over with at one time. The first time you do it, get help from somebody who has done it before. If there isn't anybody to help, I'll give the best directions I can.

You have to first throw the animal, of course, and tie its legs and have plenty of help with sitting on it to hold it still. Slit the scrotum right down the middle belly line. There are about three layers of tissue, one of which is pretty hard to get through. Have your knife razor-sharp. Now put your hand around the outside of the scrotum so you squeeze the testicles clear out. There's a cord attached to each one. You cut that away and it's done. Have the gear ready to give a shot of Combictoe or some other animal antibiotic. Some Blood Stop helps, too; it's a purple powder available from your vet.

**ROCKY MOUNTAIN OYSTERS** Save those round balls in a bucket. Then you can be like the old-time cowboys and have them next morning for breakfast with eggs. In country talk, they're called "Rocky Mountain oysters." To cook them, just bread and fry like oysters. Store in the deep freeze like any other meat while you're working up your nerve.

**Docking Tool.** The docking tool is, if anything, an even easier alternative to dehorning. My children never have been hurt by a goat, but I've been lucky. Cows of both sexes can be much more dangerous than goats. Naturally hornless animals are called "polled." A lot of the breeds now have polled strains. So the easy alternative to dehorning is to buy "muley" goats or "polled" animals. Otherwise, you can burn, nip, or saw off horns. Burning is the easiest method.

**Age at Dehorning.** If you're going to dehorn, it's much, much better to do it when the animal is 3 days old rather than later on, when the horns are big. You can dehorn a baby goat using a caustic paste or a burning treatment. Goats with horns that have already started to grow are dehorned by nipping. Baby muley goats have straight hair around their horn buttons; don't do anything to them. A baby that is going to grow horns will have curly hair there.

**Dehorning by Burning.** You can buy a special tool for this,
A kid goat with caustic on can't be allowed out in the rain. You're going to use caustic, you have to do it on a very young animal as long as their horn is shorter than ¼ inch. Calves can be dehorned this way up to 4 months of age.

Heat the electric dehorner as instructed. Heat the rod dehorner in a fire, branding-iron style, until it is really hot. Then press the hot end to the horn button. You have to have an extremely solid hold on the young animal so it can't wiggle. Having it in a stanchion that holds its head tightly is best. Hold the heated dehorner over horn, button, and horn base. Keep it there until you see a circle of copper-colored skin become visible around the horn's base. It takes only about 10 to 20 seconds. You'll smell the burning skin and hair. Do this once for each horn, and you're done forever with the problem. You can turn the animal loose right away. And you've got to do it right, or what you end up with is ugly, deformed horns—but horns anyway. To apply caustic:

1. Have your Vaseline and dehorning stick handy.
2. Restrain your animal. A miniature stanchion works well, or use a box with just space for the head to stick out.
3. Trim off hair from around horn buttons as completely as possible.
4. Cut off the horn button's tip using a sharp knife. This ensures that the chemical can get to the tissue that builds horn. If the horn button hasn't yet grown out through the skin, you'll have to cut the skin that's over the horn button with a knife to allow the chemical to get at the horn.
5. Lay Vaseline around the skin near the base of the horn button to protect that area from the caustic. It helps to stick adhesive on the button to protect it. Take adhesive off the button after you get the Vaseline in place. The Vaseline is to protect the animal's skin and eyes.
6. Dampen a caustic stick. Then apply using leather gloves or with stick enclosed in a paper towel. (Don't get it on your skin. It really eats.) Put caustic on exactly as the directions tell you. It's important to get on exactly the right amount. Too little results in a stubby horn. Too much overflows the Vaseline. If using paste, apply to the thickness of a dime. Apply stick caustic to horn button with circular motion. Also apply to area through the skin, you'll have to cut the skin that's over the horn button with a knife to allow the chemical to get at the horn.
7. You're going to have to figure out something for the next several hours until the caustic dries so the animal doesn't spread that stuff around itself or get it on its mother. You could have somebody sit and hold it for that time. Or keep it in the very confining cage you use for restraint.
8. You've got to go through this every day until you're sure you've won. If the horns get ahead of the paste, forget it. Go on to "Nipping."

**Nipping.** Young goat horns can be cut with nippers. You can get proper dehorning nippers affordably. **Pruning shears** won't work. Get some Blood Stop from your vet too. The animal will struggle, scream, and bleed. Have help to sit on it while you're nipping. Make sure the edge of the nippers is almost even with the skull. Put the nippers carefully where you want them and then do it quickly and firmly.

**Sawing.** Big, old horns have to be taken off by sawing with a meat saw. It's a hard job. You need at least three men to do a goat—two sitting on the goat and one sawing. They bleed like the dickens, but Blood Stop will lessen the blood. The hole in the horn goes right down to the nostrils. You can look down there and see them breathe. But Blood Stop seals it up in a hurry. Shake the powder on the horn right where you have cut. The wound will seal in a hurry. If you have a goat who is making itself dangerous with horns, this treatment will solve that.

---

**FOOT PROBLEMS**

**Hoof Trimming.** Some animals grow more toenail than others. You may be able to get away with no trimming, but sometimes regular trimming is the only way to keep hooves from getting so long in front that the animal can't walk normally. An overlong hoof can even split, and infection can get into the crack. Before you trim hooves, watch somebody with experience while they do it.

A horse will let you pick up its foot (usually) and work on it to trim or shoe it. A horse's hoof is first trimmed and then filed with a horse's hoof rasp. A cow is harder to trim. She won't pick up her foot for you as a horse will. Won't. Period. If she's a sedate and friendly animal, she will allow you to do her hoof trimming while she's lying down. Second best is to trim her hooves while she's standing on them. You need a special cow hoof trimmer to do that. Put her into a stanchion so her head is held still, and have her stand on a clean board so you can see what you're doing. (The only other way is to put her in a squeeze chute or rig a body sling under her belly and raise her off the floor.) See Chapter 10 for how to trim goat hooves.

**Foot Rot.** If your cow gets swollen feet and acts as if she has pain in her legs, the cause is probably foot rot. "Foot rot" means any bacterial or fungus infection (swelling, redness, etc.) in the soft tissue between a cloven-hooved animal's toes or in the hoofhead. It's a misery for the animal,
makes it lame, will reduce milk production in a milker, and will cripple a draft animal.

It can happen anytime and under any conditions, but it usually happens when animals stand in muddy or wet ground. They’re also more likely to get it if standing on frozen ground, in gravel, or on other ground types that raise the possibility of a cut on the foot where an infection can start. To prevent foot rot in stabled animals, keep bedding and pen clean and dry. Hoof trimming also protects their feet. If you have a case, it’s best if you can notice and treat it soon. Not every lameness is from foot rot. The animal may have a puncture wound or hoof abscess instead. Carefully cleaning the hoof so you can clearly see what is actually going on there is the necessary first step. Cows with foot rot can be treated with injected antibiotic and/or a dipping of the foot into copper sulfate.

Barbara Stone from Stites, ID, has a wonderful “Glenn’s grandpa” who has been around cows all his life and has passed on this remedy through her. “Foot rot can happen to just about any animal with hooves. This is quite painful to the animal. The symptoms are limping and sometimes holding the foot up off the ground. Either rope or stanchion the animal before beginning the treatment. Using a stick or a horse-hoof pick, clean off all the manure, rocks, and whatever else is in the area between the toes. Pick up the foot and just stick it in a pail of used motor oil. Leave it in there for a few minutes or as long as the animal will allow you to have it there. Sometimes it is not too easy. This treatment should be done once a day for as long as needed. Usually it won’t take more than 2 or 3 times. Try to keep the animal in a floored place that is not too wet or full of manure so the hoof can dry off. If nothing else, lock it in the barn.”

**Digestive Ailments**

**Bloat:** See Foundering.

**Constipation:** Sometimes an animal becomes plugged and cannot have a bowel movement. To check on a cow’s digestion, a vet listens at the hollow behind the ribs. One vet said that when a cow’s gut is working right, it sounds “like a spring storm.” Give mineral oil for constipation. Contact your vet to find out the proper dosage for the specific animal.

**Foundering:** Foundering happens to ruminants (cows, goats, sheep) and horses. It’s serious indigestion—quite often fatal. Not too long ago I accidentally left both the door to the grain room in the barn and the outer people door of the barn open. My enterprising milk cow, Buttercup, went in that people door, walked down the corridor into the barn. The children thought it would be nice to give Buttercup on a cup of grain a day and gradually worked her up, she could digest big quantities without harmful effect (although probably still not 50 lb. of grain per meal). When we had an alfalfa field and kept the cows pastured in it from the very earliest spring day, they got fat on alfalfa and thrived. They were there when the first little starts of alfalfa came on slowly in the early spring, and they ate them. As more alfalfa plants grew, the cows got accustomed to their feed getting richer every day. That’s why, when the alfalfa was waist-high and chock-full of food value, the cows could eat a bellyful of it as often as they wanted and be fine.

When alfalfa is cut and dried in the sun, it turns into hay and no longer has a potential bloating effect. Green alfalfa is the dangerous kind. If those same cows had been pastured in the field next to the alfalfa, on plain old grass, or on dry baled hay, and a child came to tell me they were through the fence into the hay (the green alfalfa), I would run, knowing time was precious and hoping they hadn’t already been in there long enough to eat themselves to death!

Bloat can also be caused by grazing on frosted or wet, lush, spring pastures. If you buy an animal, ask how much grain and what green feed it has been eating. Drill it into your children that animals may slurp up grain like crazy, but grain in amounts the animal isn’t used to can kill. Prevention is by far the best cure.

We’ve had all our bloat cases from over-graing. We had a nice 5-month-old billy kid. Company came to visit the farm. The children thought it would be nice to give grain to the little goat. Unbeknownst to me, they gave it a terrible quantity. That goat was not accustomed to grain in its diet at all. That evening it could not stand up. The following morning it was dead. You’ll find “Tips to Avoid Bloat” at [www.dairyherd.com/nutr73.htm](http://www.dairyherd.com/nutr73.htm).

**Symptoms of Foundering.** Foundering kills all sizes of animal. Bloat can take a 3,000-lb. bull just as easily as it did my billy kid. It kills quickly. You have to identify and treat it fast. You’re usually certain of the diagnosis because you know when your animal was overfed. They usually founder from eating either grain or unaccustomed green alfalfa in the field—or other rich green food when they are used to hay.

The worst foundering is a “bloat.” The animal’s sides swell up and up. At first it belches quantities of gas. If it is still swelled up but stops passing gas, the disease is turning fatal. You know what really happens in a bloat? All that rich food ferments inside there and makes gas. The problem is how to get the gas out before there is so much that it squeezes the animal’s lungs and causes suffocation.
Step-by-Step Treatment for Foundering

1. For any mild bloat keep the animal moving, and don't let it lie down. That helps it belch, which is what's needed.
2. If the animal belly continues to swell (especially on the left side) instead of getting smaller, get the front feet higher than the rest of the body, such as in a loading chute. Again, that's to help it belch. Or use some other system to get the front feet 6 inches higher than the back ones. Keep it standing.
3. Raising the front feet works even better if you force the animal's mouth to stay open by tying a length of hose with a rope threaded through it into the animal's mouth, over its tongue, and from side to side at the rear of the mouth, like a bit. This helps belching too.
4. If the animal isn't belching effectively yet, you'll have to resort to a stomach tube ("hosing"). Barbara Stone, Suites, ID, wrote me, "Here is the method to use in 'letting the cow down,' letting the gas out of its stomach. First, get a piece of garden hose approximately 4–5 feet long. If possible, use a ¾-inch rubber hose rather than plastic hose. Next get a piece of ⅝-2-inch black plastic pipe, the kind used for irrigation. Make sure both pieces are thoroughly cleaned. If the hose is the hard plastic kind, take a bucket of boiling water to the area where you are working. Take the garden hose and put it in the pail of water, let it set for a few minutes, and then drain completely. Take the end of the hose and carefully cut off all the rough edges. It may hurt the animal if left sharp.

"Place the black pipe in the mouth and carefully put the garden hose through it down the throat. The black pipe in the cow's mouth prevents the animal from chewing on the hose, so you can get it down. How far down you go depends on the size of the animal; on a cow you may have to go 3–4 feet before hitting the air pocket. When you hit it, they will immediately start burping and belching. Keep the pipe out of line of your face, or it will just about knock you off your feet. Keep the hose in the stomach until all the gas is out. By putting the hose to your ear, you can hear if there is any more left. Take the hose out. The animal should be on its feet in just a few minutes. If not, work with it until you can get it up. If the cow has her head lying flat on the ground, try to get her on her knees; otherwise it doesn't go in the right places. Sometimes if the animal is in the barn or is up on its feet, you can use the same method, but hold the head back slightly so the hose will slip down easily. This works on calves as well as cows.

"If you don't have a hose handy, you can use a regular rope. Stanchion the animal and take the rope in both hands, placing it sideways in the mouth over the teeth. Put this as far back in the mouth as possible. This makes the animal chew and gag and start belching. Continue this until the gas is out. But as in the other method, stay out of the line of fire. Don't put the rope down the throat."
5. Give mineral oil (or salad oil) or turpentine. For a cow-sized animal, give 1 pt. to 1 qt. oil or 2 oz. turpentine mixed with 2 c. cold water. The oil or turpentine acts to reduce foaming in the animal's stomach and so helps the gas escape through belching.
6. If the animal is down and you can't get it up, its legs are extended, and it's gasping for breath, there isn't time to call a vet. Bloat kills when it causes the animal to suffocate. You have to try "sticking," since once it cannot rise, it will soon die. For this very last resort, you stick a pocket knife in the gut to let out gas. Stick the knife into the left side exactly equidistant between the animal's last rib, and hipbone, and loin area of the backbone. That's right behind the rib cage, below the spine, in that swayback spot where it sort of caves in naturally. Have the knife point pointing forward toward the right front knee of the animal. It isn't good enough to just get a blade in there. You need to then turn the blade to make space for gas to come out. (Get your eyes out of the way of the gas, digestive juices, and food that may blow out!) Turn the blade or follow it with a small tube that will hold the cut open and allow the gas to escape. Keep the tube in place until no more gas is coming out.
7. If you stuck the animal and saved its life, great. But now it's at risk for peritonitis because of your non-antiseptic sticking. So check with your vet about further treatment.
8. For a recovering foundering case, it's best to give grass hay rather than alfalfa hay for the next few days. And no grain!

**Hardware Sickness:** That's what the old-timers call what happens when your cow eats a piece of metal. Our vet tells me that he gets around 200 cases a year. Cows, unlike goats, aren't picky about what they eat. They munch mechanically along, and if there is a nail in or near the food, it goes down too. I had a neighbor whose cow ate baling wire. That's bad. She eventually had to be operated on by the vet. But cows can survive eating nails, bolts, and even hinges if you know how to help them. The old-timers came up with a remedy for hardware sickness that's still used. Of course, prevention is the best remedy of all, so check your feeding places, keep your eyes open when you're walking around in your pasture, and pick up any small, loose metal pieces you see. Once in a great while, a goat gets hardware sickness too.

**Symptoms.** The animal stops eating. It gets a miserable look in its eyes and will stop going out to browse with the herd. It just lies around by the barn being reluctant (but not unable) to get up. There is no fever.
Treatment. The old-timers went to town, bought a magnet, and forced the animal to swallow it. If the metal has not progressed beyond the big stomach region, this will save your cow. The magnet grabs the metal and pulls it to the bottom of the cow's stomach. It doesn't ever pass out. She has a magnet and metal inside for the rest of her life. But the important thing is that she doesn't die. When she starts eating again, you can relax and feel safe. Veterinary suppliers sell small, very heavy, smooth, oval-shaped magnets for this very purpose.

Getting to a vet will make treatment easier. In the first place, a vet can make a surer diagnosis than you can. First take the cow's temperature. The above symptoms with no fever may lead you to suspect hardware sickness. But the animal doctor will have a metal detector. Doc can put the earphones on and run the rod around her belly. If it screeches, Doc knows for sure that it is hardware sickness and also knows the location of the metal. If it goes untreated for too long, the metal can tear up her insides. The vet will probably give her a dose of medicine to stimulate her bowels, since hardware sickness makes them stop moving. It will make her have diarrhea for a couple days, but in this sickness that's a good thing. Then the vet will make her swallow the magnet. And Doc may give her a shot of antibiotic and send some home with you to give to her for 2 more consecutive days.

Our vet tells me that they have to operate on only about 2 of those 200 cows a year with hardware sickness. If the cow doesn't recommence eating and doesn't seem perfectly all right by 5 days after the onset, take her for surgery, which is expensive but maybe not as expensive as a cow. Ask and see.

Diseases/Infections

NOTE: Any animal that does very poorly—and you don't know why—is not meat you want to eat.

ABSCESS: An abscess is a localized infection, usually right under the skin, like a big pimple. Dynah Geissal wrote me advising, "Leave an abscess alone until it is ready to lance. At this time the hair will pull out easily near the head of the abscess. After lancing, treat with iodine. Abscesses are sometimes caused by dirty needles, so be scrupulously clean when giving shots."

CANCER: If it's where you can see it, there'll be a hard protruding lump that just grows and grows while the rest of the animal does poorly. Make sure it's a cancer lump and not merely an infection. You do this by jabbing it with a knife. An infection runs pus; a cancer is hard clear through. If it is a cancer, take the animal away, shoot it, and dispose of the body.

CUT: Clean and then treat the cut with a product called Bag Balm, which is available from veterinary outlets. Bag Balm is also good for humans, and other cuts on your animals can be cleaned and treated with it. But use separate cans of Bag Balm for man and beast. For badly infected wounds, inject antibiotics.

INFECTIONS: Lance the wound by cutting it to let it drain. Put a healing salve like Bag Balm on it. If that isn't good enough, use antibiotic shots.

MASTITIS: For this udder infection and other dairy problems, see "Dairy Vetting" in Chapter 10.

PINEYE: People pinkeye, kitten pinkeye, and rabbit pinkeye are all disagreeable. We take the kids to the doctor for a prescription or get some Murine eyedrops; that works for kittens and baby rabbits too. Dynah Geissal says goat pinkeye is "usually caused by dusty feed but sometimes by bacteria. Treat with diluted lemon juice twice a day. This usually works, but if it doesn't, you will have to resort to the more radical treatment of injecting antibiotics into the eyelid! Pinkeye must be treated because it may lead to cancer eye, which causes blindness, severe emaciation, and death."

Bovine Pinkeye. We have a lot of this ailment around here—it starts right after the face flies do, in late June or so, when the weather dries out and starts to turn hot. The face flies hang around a cow's eyes and drive her crazy. We try to help by soaking rags in a face-fly discourager and hanging them up on a rope so the cows can scratch themselves on it. But the best prevention is choosing a pinkeye-resistant breed of cow. Breeders have paid a lot of attention to resistance to this disease. Black Angus cows can list among their fine selling points that they are pinkeye-resistant. Short-horns are not; I know from personal experience. Charolais are supposed to be resistant, but some still get it. Herefords are more susceptible than Black Angus.

Bovine pinkeye comes on very fast. It generally happens on only one side at a time. The eye turns white all over and looks ulcerated and awful. You'll know the instant you see the cow that something is terribly wrong. If you don't have pinkeye-treating experience, or even if you do, the best thing to do is load up the sick animal and get her to the vet immediately, because every hour really matters with this rapidly progressive disease. If you're in doubt, phone the vet first to discuss if it is what you think it is. It's a good idea to check all the cows' eyes each morning and evening in face-fly season, as a matter of routine, to catch any pinkeye when it's just getting started. In some cases, with quick action, the vet may be able to save the eye. Or you may lose that eye but prevent the disease from spreading to the other eye. Then you've got a one-eyed cow, but otherwise she will be functional.

If you lose both the animal's eyes to pinkeye, you'll have to sell the cow for hamburger or eat it yourself, because it'll starve anyway. I know an old-timer who says the way to treat it is to get a handful of salt and rub the affected eye with all your might. Lane Morgan says her vet gave them something in a spray can (the spray was purple) that worked.

PNEUMONIA: Calves and goats get pneumonia. The symptoms are similar to the human disease. Animals with
pneumonia have a very snotty nose and maybe runny eyes. They run a fever, are weak, and are obviously very sick.

Their breathing is unnatural—raspy, maybe with coughing. The treatment is to keep the animal in as warm and dry a place as you can, feed frequently, and give Combootic shots for 5 days. Coddle it a while more, because they can relapse.

**Preventing Pneumonia in a Down Cow** From Barbara Stone, Stites, ID: “Our big Holstein cow went clear down during the night over the holidays, and she was down for almost 3 days. She had somehow hurt herself and couldn't get up. If you have a cow down, it's important to prevent her from getting pneumonia. It was awful cold at that time. We couldn't get her in the barn. We just had to keep old blankets and straw around her for the time she was down. We put feed and water in front of her, and she ate and drank. She finally did get up, to everyone's joy.”

**Red Water:** Dynah Geissal wrote me, “This disease is named for the way the urine looks when cows have it because there is blood in their urine. In goats it is detectable only with a microscope. I had 3 goats autopsied by live-stock vets, one of whom told me the goat had starved to death. In fact, they do look starved. A pet vet did a fourth autopsy and found blood in the urine and then discovered the cause. After losing half my goat herd, I started inoculating and have never lost another goat to this disease. Red water is caused by liver flukes, which are carried by snails. If your goats graze or water in places that the fluke-carrying snails inhabit, they could get it. Ducks help to keep this problem under control by eating the snails. Having well-drained pastures and not allowing the goats to use natural watering places cuts way down on the problem—but inoculating eliminates it.”

**Ringworm:** Ringworm is a fungus. Supposedly the animal kind can’t spread to humans, but I know better. First I got a spot on my arm. It kept breaking out again on my arm. We couldn't figure out where it was coming from. Then we discovered patches on Marietta, our milk cow. I'm the one in the family that milks. (Mike runs them in at night and feeds them, and I come along with the bucket and do my thing.) So it had to be more than coincidence that Marietta and I had ringworm at the same time. The doctors have a new treatment now for people ringworm, a one-shot painting that wipes it out. The ringworm eventually spread to all the cows. It took the hair off in (usually) roundish areas, leaving a kind of whitish, scaly surface.

Dynah Geissal treats goats that have ringworm with lemon juice, applied 3 times a day. I've found that iodine dissolved in glycerin is a good medicine for ringworm. You can get ringworm medicine from your vet. You paint it on once, and that's fine until you find the next spot. In the old days, they just left it alone. It was a winter affliction that the cows sloughed off in their spring molt. Another old-time remedy was to get an old rag and tie it on a stick. Dip the rag into a can of used motor oil and run it over the ringworm areas (not near eyes).

**Scours:** Scours means animal diarrhea. Usually it's the babies who get it. Chilling, a change of food, or a bacterial infection can cause it. For treatment of a kid or calf with scours, see chapter 10. For older animals with mild scours, Dynah says she treats "with ginger fed with grain. More severe scours is treated with Kapectate.”

**White Muscle Disease:** Dynah says, “The symptom is stiff hind legs. It occurs in selenium-deficient areas. It is prevented by feeding a mineral mix that includes selenium.”

**Parasites**

**Lice:** Lice can turn up on practically anything, man or beast. And don't let anybody kid you and tell you that animal lice leave human beings alone. I know several people whose whole households have gotten horrible cases of lice from animals, in one case from a neighbor's milk cow. Animal lice don't generally make the jump to people unless you get really intimate—like leaning your head against the cow. But once you've got 'em, you have a fight on your hands. If you can help it, don't go home. Take a hot shower. Wash your hair with a strong soap. Wash all the clothes you were wearing in detergent and hot water. If still in doubt, buy a can of garden spray that's good for flying bugs (terribly strong stuff, I know, but nothing lesser that I know of is really effective) and spray your car. Take off your shoes and spray them.

If the infestation of lice is in your whole family or your house, you're going to have to go through this battle again and again. It won't be easy, but in the end you'll win. I've been through it. Wash all the clothes and bedding. Shampoo and bathe the children. Fumigate the house thoroughly. If it doesn't work, do it again. And you have my sincerest sympathy. This is one of the most miserable afflictions I can think of—and it's the same for the cow or chickens or other critters that have 'em. Malathion is an effective spray, but it's terrible inorganic stuff. A new treatment of whitewash in your animal shelter and crankcase oil on the roosts, in the case of chickens, has been known to work. Makes me itch and scratch just to write about it.

**Maggots:** Maggots are caused by flies that lay their eggs in a wound. When the eggs hatch, the little worms live in the animal's flesh. It is a terrible sight. When I was little we had a lot of trouble with bears getting into the sheep. Often the bears succeeded only in getting part of a sheep. I remember vividly helping my daddy. He would hold the wounded sheep down while I poured the dark, thick anti-maggot medicine all over where the worms were writhing in the exposed flesh. So be forewarned. If your animal has an open wound in the fly season, you must keep a salve on it or else pour an anti-maggot solution over it.

**Worms:** Medicine for worms can be given via an animal's food or drink, or in a shot. It depends on the animal and on the worm—the varieties of which are legion. Don't treat unless you actually have the problem.

**Introduction to Butchering**

For specific species butchering instructions, also see the section in this book dealing with that animal.

The tiger naturally eats nothing but meat. Man naturally can thrive on a diet of part meat which, like the tiger, we have to kill to get. I don't think much of people who say they like to eat meat but go "ick" at the sight of a bleeding animal. Doing our own killing, cleanly and humanely, teaches us humility and reminds us of our interdependence with other species. My husband adds that there would be fewer wars if people were doing their own killing and knew what it was to have to cause death to a living creature. I'm
I grew up on a farm and in a climate where meat and dairy products were naturally an important part of the diet. By “naturally” I mean that as you go farther north, or farther up in altitude, you get into climates where fruits and vegetables are harder to grow, but forage crops—food for animals—like brush, grass, and hay can still do well in season. In such areas your diet naturally tends to lean away from fruits and vegetables, which become ever more limited in selection and in season as it gets colder, and toward meat and dairy products—foods that can be harvested even in snowdrifts, foods manufactured by animals that can eat grass in summer and hay in winter, 2 food sources that humans can’t eat.

Killing that provides for the ample continuation of the species is acceptable to nature. In other words, we eat the extras—especially the extra males. No one wants an adult male of these domesticated species except for meat. No one, that is, with the exception of the female (if only for a moment), so there have to be enough males for breeding. The other exception is castrated males that are work animals, namely oxen. Uncastrated males don’t make good pets, are expensive to feed, and don’t produce the milk or babies that make the females a valuable part of the farmstead ecosystem.

We also eat the females that are past reproductive age—or even younger females, if the herd has grown to a size where its natural environment couldn’t support it anyway. And we may kill to improve the genetic heritage of our surviving breeding stock—thus eliminating less hardy or less productive individuals. Killing purely for the sake of sport is wasteful unless a species has ever-reproduced to the point where its ecosystem can’t support it anyway. Don’t kill members of a species that doesn’t have extras.

Home Butchering

Qualifications and Preparations: Unless you’ve had a college course in comparative anatomy or dissected a cat or two in a zoology course, you may not be able to distinguish one muscle bundle from another. When I was a little girl, my mother believed that every situation could be made to have educational value. As the teachers of subjects

Custom Slaughter and/or Cutting

Some people send their animals to a custom-cutter to be butchered, cut, wrapped, and quick-frozen. The cost is figured per pound and is often waived in part in return for the hide, so many pounds of the hamburger, or some such. My friend Stephen Scott wrote me: “I take the sissey way out and send them off to a professional butcher. It is not an expensive proposition anymore to ship pigs, have them butchered, cut up, and wrapped, and have the hams and bacon smoked, but I prefer it to the alternative. We are lucky to have a few places left that do this kind of thing in our area. Twenty years ago there were at least 10 places that would do custom butchering; now there are just 2. One of them comes out to pick the pigs up with his own truck. For the other one, you have to haul the pigs to him—haul them yourself or hire a livestock trucker to haul them for you. I don’t have a trailer that will haul livestock, so I have to pay 15 bucks to have the butcher come and pick them up. We raise three pigs: one for ourselves and two that we sell. We split the hauling fee so that each one of us has to pay only 5 bucks apiece. Not a bad price considering the trouble that you can have on the road with 3 scrappy 200-lb. porkers.”

Another possibility is custom slaughterers who work from a mobile rig and will visit your place for the day. If you want to hire out some or all of this work, make arrangements in advance with a local person, find out what the price will be, and make an appointment for a particular place, day and time.

Instructions for the Meat Cutter: He’ll package it just right to serve your family’s size. Tell him how thick you want the meat cut, how much you want your roasts to weigh, how many steaks, chops, etc., you want wrapped in each package, what percentage you want made into burger or sausage, and if you want any of the meat cured. You may want to get the bones back. A reader wrote me, “When we send a beef to the butcher to be cut and wrapped, we request that they give us all the bones too. We pressure-cook them, let them cool, and then pick the meat off them (there’s a lot!). We can the stock with some of the picked-off meat and some onion slices in each jar. It makes a great stew base and makes the budget stretch farther.”
like “Hellenistic Marketing” and “Music of Ancient China” say, it’s bound to be useful sooner or later; you might be surprised just when. So whenever Mother cleaned a chicken, she would call me over and have me identify all the various abdominal organs. Eventually, I struggled through 3 years of pre-med at the University of Illinois at Chicago. But chemistry, trigonometry, and physics were my downfall. So I didn’t become a doctor. But I got straight As in all the anatomy and dissecting-type subjects. I have just listed for you my credentials for writing about meat cutting—above and beyond having done it.

“Butchering” is when you kill, skin, gut, and quarter the animal. Then you hang the quarters up to age, in the case of most animals, or merely to cool overnight, in the case of pigs. This book does not describe professional butchering; it assumes that you can probably tell bone from meat from fat—and not necessarily much more. Its essential goal is to enable you to get your meat from hoof to pan yourself, and I trust it will accomplish that. There are cuts here that you don’t see in the store, but a professional butcher has lots of expensive power-cutting equipment that you don’t want or need to buy. You’ll understand any procedure better after you try it a few times. The school that best teaches you something is the one where you actually do it enough times to get comfortable with it. The biggest hurdle is getting started—getting the confidence that you really can do your own butchering.

I’ve tried hard to make the directions that follow clear and dependable. It would be even better than reading this chapter, however, if you could butcher and cut up an animal with somebody who is experienced. If you are inexperienced and must be on your own, it’s a good idea to start with something small—such as a chicken or rabbit—and gradually work up, rather than trying to learn on a 1,200-lb. cow. The basic principles are the same.

In general, if you are careful with your basic preparation (don’t shoot the animal if it’s excited, get it thoroughly bled out, don’t spill intestinal contents on the meat, get it cool, keep it clean, and don’t let the meat spoil), you really can’t go too far wrong. You’re going to eat the meat yourself. If your steaks are triangular, they will just give you a good laugh every time you eat them.

Jacki Robinson, Reddick, FL, wrote me, “Fifteen years ago my husband and I decided to move out of the city into the country . . . . We bought a 5-acre postage-stamp farm that was already set up with garden space, barn, root cellar, and chicken house. After some repairs we were ready to start, and we did. We got a milk cow, a beef calf, goats, chickens, geese, guineas, ducks, bantams, pigs, and bees.

“When it came time to butcher our pig, we could get no help from any neighbors. (They were sort of close-knit and related to everyone but us. The consensus was that we would never make it.) So we went to the library. Our beautiful librarian loaned us a copy of your book . . . . My husband butchered our pig while I sat on top of the truck with your book telling him what to do next. The pork chops looked like triangles, and there were many unnamed pieces of meat, but it sure tasted good. After that, the neighbors were a little friendlier. I checked out your book so much that I finally bought it. Living out here is so precious to me. Growing a child and the food we eat are enriching my soul.”

Once you have gotten the animal killed and the meat cut, you need to preserve it (or have a big barbecue and eat it immediately). So before you commence slaughtering, be sure to decide how you are going to preserve the meat, and be prepared to get that meat processed within the necessary time limit. This chapter contains a section describing every possible way of preserving meat, including freezing, canning, and drying. The last section tells how to make homemade soap from surplus animal fat and how to tan skins. (Candle-making info is in Chapter 1.)

**Books and Supplies:** A good one is *Basic Butchering of Livestock and Game* by John J. Mettler, Jr., D.V.M. (1991). It covers beef, pigs, sheep, deer, poultry, rabbits, small game, goats, horses, and also buffalo—as well as pickling, smoking, and curing meat, and how to build a smokehouse and make sausage. *Butchering, Processing and Preservation of Meat* by Frank G. Ashbrook contains material from USDA bulletins. Texas A&M offers meat science info and training seminars such as “Beef 101” and “Sausage School!” Contact the Rosenthal Meat Science and Technology Center, Dept. of Animal Science: 409-845-5651; fax 409-847-8615; meat.tamu.edu. The American Meat Science Ass'n lists classes, such as Pork 101, on its website: 217-356-3182; fax 217-398-4119; info@meatscience.org; www.meatscience.org.

Forschner knives at German products that are very good. They are available only from butcher supply houses. Recycled professional (Chicago Cutlery's Biocurve) processing knives are available (bargain!) from Tim Shell: 540-885-4965; 407 Mt. Solon Rd., Mt. Solon, VA 22843-9718; tschell@fristva.com. To cut up something large like a beef, a band saw really helps, but they are very expensive. We don’t have one. Sometimes you can find a small saw secondhand for a bargain price. Some people make their own.

**Fit to Eat?**

*What’s Live and Fit to Eat?* Don’t choose an unhealthy animal for slaughter. If you suspect an animal of being unhealthy, get it checked by a veterinarian and treat it until it’s healthy again. (Then wait for the antibiotic to wear off.)

*What’s Dead and Fit to Eat.* If you know an animal has just died, and you know why, here are your rules: don’t eat an animal that died of a disease (other than a non-microbial-type disease, like foaming). Do eat an animal that died of an injury, like getting hit by a car. It would be a shame to waste the meat. If you don’t know why the animal died, or if it has been dead awhile, definitely don’t eat it. (When in doubt, throw it out.) As soon as possible, as much of the blood as possible must be drained out. Getting that accomplished is very important and very necessary if you want the meat to look normal and keep normally. Don’t butcher or eat any animal that has received any kind of medication within the last 2 weeks or that has been recently wormed or treated for external parasites. Check the directions on the medicine container for the precise withdrawal periods after which butchering is safe. The time varies according to the particular treatment.

**Your Meat Inspection:** After the slaughter and evisceration of any animal, examine the internal organs and the carcass carefully for any visible abnormalities that might suggest the unsuitability of the meat for food:

1. Local bruises and injuries, enclosed abscesses, and single tumors are conditions that the professionals simply cut away and discard; the remainder of the animal is fine to use.
2. Worms in the intestinal tract are routine and don't disqualify the meat.
3. If you find inflammation of the lungs, intestines, kidneys, inner surface of the chest or abdominal cavity, or (in the case of sheep) numerous yellowish or pearl-like growths scattered throughout the organs, call your vet and discuss whether you should use the meat! (When in doubt, throw it out.)
4. If a liver has many white-filled spots on it, you have coccidiosis disease on your farm. The livers need not be fully spotted. Any slight discoloration is a sign of infection. Chickens can get it; so can various other varieties of poultry, rabbits, and sheep. Do not eat the meat of infected animals! Burn the carcass.

**Butchering Meat for Sale or Trade.** The Federal Meat Inspection Act requires that some meat that is to be sold or traded for human consumption must be slaughtered under inspection in an approved facility under the supervision of a state or USDA meat inspector. For more details about these regulations, see the Chapter 9.

**Radioactive?** If they ever drop the bomb, or if a nearby nuclear power plant or nuclear waste dump blows up, don't eat any internal organs, bone marrow, or animal skin. The muscle meat will be safe if you keep it absolutely dirt-free. Milk from dairy animals will be contaminated if your animals ate contaminated feed or drank contaminated water. It will be okay if they ate clean feed and drank clean water.

**Other Poisons.** Relative to the industrial-chemical era in general, if there are any poisons in the animal's system, they will wind up getting concentrated in the brain, liver, and kidneys and in the fat. So minimize your eating of animal fat not only because of cholesterol but even more because of DDT and other chemicals!

**When to Butcher:** Around here the best months for butchering are late October, early November, and late February. That's because then the weather is cold enough so the meat will keep, but not so cold that everything keeps freezing on you. An outdoor temperature of around 35°F is ideal, since spoilage bacteria do not grow well in such a cold environment.

Another factor in the timing of slaughter is food supply. There is often a time that's economically best for killing. For grass eaters it's when the grass gives out in the autumn, which is around the same time as when the weather gets cold enough so the meat will keep. Another economically determined time is when the critters will no longer put on much extra meat relative to the food they eat, when they're basically done growing. That's why ducklings are ready after about 10 or 12 weeks.

Small animals like rabbits and poultry that will go straight to the refrigerator or the table can be butchered under any weather conditions at any time of year. Larger animals that will be quickly barbecued whole, like small pigs, lambs, or kid goats, can also be butchered in summertime, even without refrigeration. But for larger animals, you'll have to consider how long it will take you to get the animal butchered, how long you want to hang it, how long it will take you to cut it up, and what plans or facilities you have to store the meat (canning, freezing, locker storage, drying, etc.).

Avoid slaughter in high winds, when dirt might be blown into the workers' eyes or dust onto the carcass. Most people avoid slaughter in hot weather, except of a small animal such as a goat. Hot-weather slaughter is best done in the late evening hours. In most families the men butcher and cut up and the women wrap, but I know some country women who take great pride in cutting up the meat themselves. Wear old and very washable clothing to butcher. Most people get blood, etc., on their clothes. Wash your hands and arms frequently.

**Preparations for Slaughter:** All large animals are typically killed, skinned, and eviscerated outside and then cut up on an inside counter. Small animals may also be cleaned inside the house.

**Checklist Before Large Animal's Slaughter**

1. Choose ahead of time a site with clean running water handy.

2. Locate a tree with a high, healthy limb or a building with a high beam strong enough to hang the carcass from. You'll also need a block and tackle or strong rope or singletree and hoist to raise the animal's rear end.

3. Have ready a gun or pistol (.22-caliber or higher rifle or pistol with cartridges) and know how to use it.

4. Collect a few very sharp knives and means to sharpen them again (a steel knife sharpener or Carborundum whetstone), and a meat saw. Razor-sharp knives minimize waste by enabling you to trim closely and precisely.

5. Gather buckets to hold liver and heart (you need a 4-gal. bucket for one cow's organ meat) and clean cloth or food-grade plastic to cover the animal after the carcass is skinned and eviscerated.

6. If you're butchering a larger animal, you'll also need a regular wood-cutting saw for cutting the animal in halves. The meat saw blade is too thin for that job.

7. It is also helpful to have a bucket of warm water with a heavy dash of vinegar in it for washing your hands when they get sticky, especially after you've been handling the innards and before you go back to work on the meat.

8. It's a good idea to clean and defrost your freezer before putting a large amount of meat in it. And check whether you have enough space available in your freezer. If you have a small freezer and a large animal, consider boning it out and cutting away and discarding the fat.

9. If possible, pen the animal the day before slaughtering. Do not feed it for 24 hours before killing, but do provide ample access to water during all that time. Withholding feed helps because then the guts are less bulky. Access to water helps complete bleeding out, results in brighter-colored lean meat, and makes skinning easier. But if penning isn't possible, don't worry. Your meat will still be all right.

10. The offal (butchering residue) can be awful if you don't have a plan to deal with it. See below.

11. Plan how you'll age the meat. See below.

12. If you're planning to freeze the meat, you'll need
OPTIONS FOR THE AwFUL OFFAL: You could bury it in the garden, give it to the chickens, push it over a cliff, feed it to the pigs, or compost it.

Feed It. It takes chickens a long time to eat up cow in­nards. Pigs can take care of them right quick, but for either pigs or chickens there’s a concern that eating in­nards reinforces the animals’ parasite supplies. You can solve that problem by boiling the in­nards at least an hour, and preferably several, before feeding them to the animals. In that case, you need a huge pot and an outdoor place to get a fire under it. That’s probably the best solution. In warmish weather, in­nards can get stinky pretty fast.

Compost It. Another solution is to compost the waste—in­nards, extra bones, hides, and blood (but not fat). Add them to your yard clippings, manure, peelings, food left­overs, feathers, and anything else organic. Mix everything with a layer of soil. Let it sit a few weeks and then stir it again. But then you have to cover it in a way that guarantees some critter won’t dig it up. Since some of these items decay very slowly, the delayed action continues to feed nu­trients into your garden for a long time.

Remember: If not thoroughly hied out, the meat won’t be pale in color. It will look “funny” and won’t keep as well. And be careful to tie off rectum and to not let contents of the intestines spill onto the meat. That’s how it can get contaminated with the likes of E. coli.

GENERAL PRINCIPLES OF AGING MEAT: Aging, a bacterial breakdown of complex proteins in the muscles that adds to flavor or tenderness, naturally begins when the meat is cool. If you choose to age the meat, keep it at about 40°F. Warmer temperatures increase the danger of spoilage. Colder temperatures slow down the process. Aging large animals for about 10 days should be sufficient. Deer will age in a week. Antelope should not be aged longer than 4 days. Very lean carcasses are not suitable for longer aging because they dry out too much. If the animal was less than a year old, the meat doesn’t need aging at all. Don’t age pork and pork-type meats (bear, wild boar, etc.).

Aging is done after skinning and gutting and before cutting up—except into halves or quarters (whichever is suitable for the size of the carcass). The aging process helps tenderize the meat and mitigate wild flavors. Small animals may be wrapped in a damp cloth and aged in your refrigerator for a day if they are young, for up to 4 days if they are old. Somewhat larger carcasses may still be small enough to be cut up and aged a while in your refrigerator. How long or whether you age large animals will probably depend a lot on the age of the meat and the temperatures the meat will be exposed to.

Wild hoofed game is often hung about 10 days; it needs to be kept at 35–40°F for that period. If you have a walk-in cooler where you can hang your meat and keep the temperature above freezing but below 40°F (meat will actually turn out more tough if frozen within 24 hours of butchering), you could age it for 1 week, or 2, or as much as 3. If the weather is cool enough, let the meat hang in one of your own outbuildings with the door shut, to prevent wandering canines from helping themselves and to protect it from freezing at night. If you don’t have facilities to hang the meat that long, or if the temperatures are getting too hot, by all means go ahead and cut it up. It may not be as tender as it might have been, but at least it will be edible.

About Cutting Up

CUTTING TERMINOLOGY
Chop: Lamb, veal, and pork terminology for what’s called “steak” on a beef or elk
Cut up: To take the quarters into your house, onto the table, and cut them up into cooking-type pieces
Inside: Inside the chest and abdominal cavity
Outside: On the side where the skin was attached

Tips: Mini-steaks, possibly literally the tip of the muscle bundle

CUTTING-UP OPTIONS: Basically, you’ll go one of 3 ways, or some combination thereof, with your cutting up:
1. Cut meat into chops (steaks), roasts, stew meat, and hamburger/ sausage according to the part of the animal. This is the conventional way to cut meat.
2. “Bone out,” which means to remove all the muscle bundles from the bone. If you have limited freezer space, if you plan to can all your meat, or if you can’t stand working with a meat saw, boning out is the way to go.
3. Bone out and then grind the meat of the entire animal for hamburger/ sausage. This is a frequent farmstead choice when an older animal that might be tough needs to be cut up. It gives you a good use for the meat with­out creating a struggle for the cook to make it usable.

THOUGHTS BEFORE YOU START CUTTING: Ask the cook about his/her preferences. Your animal is going to be­come spareribs, hamburger, stew meat, steaks, roasts, and soup bones. But spareribs can also be soup bones or can be cut into smaller chunks for stewing meat. Stew meat—even steaks and roasts—can be made into hamburger or sausage. Roasts can be cut into steaks by just cutting them into slices across the grain. The usual practice is to make the more tender cuts into steaks. You can learn to tell the difference. The best meat for steaks is a lighter color. It is sad but true that the least desirable cuts require the most work.

Cutting Technique. Always try to cut either outside the muscle bundle or across the grain of it (across the muscle
fibers). A commercial butcher works with frozen meat and power saws. He or she can saw out all the cuts. It's best for you to first cut with the knife through the meat part and then saw with the meat saw across the remaining bone if you want to include the bone. Meat is almost impossible to saw because it's wobbly and won't hold still. If you freeze it before butchering, that problem is eliminated, but then it will be a lot harder to find your way around in the carcass and harder to cut it with a knife.

**Cut Portion Sizes.** The thickness of your steaks or chops is truly and purely a matter of the cook's preference, anywhere from ¼ inch to a full inch or more. Personally, I like goat and venison steaks ¼ thick (wild meat is usually cut about half the thickness of beef), beef ¼ inch, and lamb ⅛ inch thick. The ideal size of your roasts depends on the size of your family. Figure out how much meat per person per meal an average roast needs to supply (⅔ lb.?) and multiply that by the number of people in your family. If some of your people are small eaters, lessen it accordingly. Add an average ⅛ lb. per person for roasts that contain a bone.

**Preparations for Cutting Up.** Have ready 3 containers—such as cardboard boxes, enamel or stainless steel dishpans, or plastic buckets or pans—and a fourth if you plan to set aside some of the meat for jerky. One container is for the unusable trimmings you will give your cat, dog, chickens, or pigs to eat. The second is for pieces of meat that you intend to grind up for hamburger or sausage. The third is where you put the bones and ribs, which are bulky and would crowd your tabletop, until you have a chance to wrap them and put them away in the freezer. The fourth holds long, lean strips (at least 3 inches long) without too much gristle and with every bit of the fat cut away; these make the best jerky. (Note that you can't make jerky from pork because of the trichinosis threat.) You can sort these out from among the general to-be-ground-for-hamburger or sausage pile.

A big sturdy table is a good place to do the work. Everybody I know uses the kitchen table. We have a piece of plywood cut to fit the top of it for cutting-up days. You may want to also cover that with butcher paper before starting.

**Organ Meats:** Don't age organ meats. They don't keep as well as the muscle meat. Brains, sweetbreads, kidneys, and tripe are the most perishable. Cook any or all of them within 24 hours of slaughter. The tongue, heart, and liver can last longer but should not be deliberately aged. You can store liver, heart, and tongue in your freezer.

**Sweetbreads.** "Sweetbreads" are the thymus gland. It looks pinkish grey and sort of spongy. I haven't included them in the regular butchering directions because most people ignore them, but the sweetbreads of calf and lamb (not pork) are edible. Lane Morgan says they're delicious. Sweetbreads are situated at the base of the neck near the heart.

**Tripe.** "Tripe" is the lining of the first and second stomachs of calves. I didn't mention it in the coming butchering section either, but it's also edible. "Plain tripe" means the lining of the first stomach. "Honeycomb tripe" means the lining of the second stomach and is considered better-tasting than plain tripe. You get the tripe by cutting the stomachs away from the rest of the intestines, cutting them open, and turning them inside out. Wash and rinse at least 3 times in clean water. To prepare tripe, boil at a low temperature, covered with water, until tender (4 hours or more). Then refrigerate until wanted for a recipe.

**Of Suet:** Suet (also called tallow) is the hardened fat around the kidneys and loins of sheep and cows. You can use hogs' intestinal fat and all sheep and calf fat for making soap and candles and for bird feed. Suet is used in many recipes, and it's also good to feed to wild birds in cold weather. Many wild birds (especially insect-eating birds, which you want to keep around) love to get suet during the winter months. These birds can metabolize the energy in suet more efficiently than that in seeds. Be careful, however, to leave out all salt, as it will kill most small birds. You can offer suet to birds by freezing it until winter and then setting a lump in a hanging container (a wire basket or a perforated plastic bag works well for small clinging birds) or sticking it to tree bark or cones. Woodpeckers enjoy suet poured into a hole in a log. Suet poured into a coconut shell half will be eaten by all sorts of wild birds. Or you can mix in corn, seeds, or peanuts for a bird pudding!

**Basic Bird Pudding** Spread seeds, grains, popcorn, cracked corn, peanuts, granola, cornmeal, cheese, oatmeal, dry cake, or what-have-you in a container. Heat suet in a double boiler and pour hot fat (⅓ to ¼ lb. of fat to 1 lb. of mixture) over mixture until it is covered. Birds need grit; ordinary sand will do. Add ½ t. sand to 1½ c. suet. Let set. Then pour onto a table unless you have prepared it in a tit-bell or coconut holder. In spring, when insects, worms, and new growth appear in the softened ground, stop suet feeding. For more wild bird feeding recipes, consult The Bird Table Book in Colour by Tony Soper or My Recipes Are for the Birds by Irene Cosgrove.

**About Cooking and Eating Meat** Being faced with eating an entire large animal may require quite an adjustment. Maybe in the past you've learned only to cook hamburger 365 ways and are uncertain about coping with many different cuts. Don't worry: the ways to prepare and cook meat are infinite. Big hunks are roasts. Little tiny hunks are stewing meat, shish-kabob meat, or slicing meat for Chinese cooking. Medium-sized flat pieces of meat are steaks or chops. Very thick flat pieces are roasts. Bones with very little meat on them are soup bones. The ribs are "spareribs" that you bake with barbecue sauce on them. With a Dutch oven and a frying pan or wok, you'll have no trouble consuming even an entire cow. Cook the roasts and ribs in the Dutch oven with the lid on, the soups and stews in it with the lid off. Cook the flat meat in your frying pan.

**Rationing:** Don't eat steaks every day the first three weeks—you'll end up eating hamburger every day the last three! Rotate. Have steak one day, then hamburger, a roast the next, then a stew, soup, or ribs. That system will make the various cuts come out about even. Or, if you want to consume less meat than that, spread the system out so
you're eating the meat only every other day in the same rotation. You can be using the leftover supper meat on your off-meat days for cold cuts, hash, or ground-meat sandwiches. If you have a pig in your freezer too, add pork to your rotation. Most of the pig makes good breakfast meat. Or you can limit your meat consumption to once per day and add a couple of nights of pork roast, ribs, or chops, or add the "breakfast" pork meats to your evening meal rotation. If you use about as much pork as you do beef, you can eat up about 4 pigs while you are eating up 1 cow using this system.

**TENDERNESS:** Home-grown and wild meats may vary in age at butchering time and thus in tenderness. If you can't butcher your animal young, you could make hamburger or sausage out of the whole thing. The quick, hard-working old-fashioned way to tenderize is to pound the meat with a wooden meat mallet or a special steel hammer with a corrugated pressure-surface made for pounding meat. Or you can precook the meat, covered with water, for about 15 minutes. Discard that water and proceed with your regular recipe. (This process both tenderizes and floats away some of the wild, goatly or muttoney tastes.) Or cook the meat longer, or cook it a short time in a pressure cooker (15 lb. pressure for 15-20 minutes). Or marinate it, which may improve flavor as well as tenderize it. Popular marinades include a mixture of vinegar and lemon juice; grated onions and oil; tomato juice, water and lemon juice; water and vinegar; French dressing. The meat is typically soaked in the marinade in the refrigerator for 24 hours and turned in the liquid several times during that period. Or use a commercial tenderizer, which is made from a natural enzyme and will soften the toughest meat in a few minutes.

**Coffee Tenderizer.** Frank Womack, Jr., Pomeroy, WA, wrote me, "Coffee is a means of tenderizing about the toughness of the meat. The quick, hard-working old-fashioned way to tenderize is to pound the meat with a wooden meat mallet or a special steel hammer with a corrugated pressure-surface made for pounding meat. Or you can precook the meat, covered with water, for about 15 minutes. Discard that water and proceed with your regular recipe. (This process both tenderizes and floats away some of the wild, goatly or muttoney tastes.) Or cook the meat longer, or cook it a short time in a pressure cooker (15 lb. pressure for 15-20 minutes). Or marinate it, which may improve flavor as well as tenderize it. Popular marinades include a mixture of vinegar and lemon juice; grated onions and oil; tomato juice, water and lemon juice; water and vinegar; French dressing. The meat is typically soaked in the marinade in the refrigerator for 24 hours and turned in the liquid several times during that period. Or use a commercial tenderizer, which is made from a natural enzyme and will soften the toughest meat in a few minutes."

**COOKED OR RARE?** Most people know about the possibility of trichina in underdone pork or *E. coli* from undercooked beef, but few know about toxo from underdone lamb. Toxoplasmosis is a parasite that can be carried in any animal, including humans, but it reproduces in cats. Wash your hands after contact with cat litter.

**NOTE:** All meat should be cooked enough to reach 160°F and change color throughout. Also wash hands after handling raw meat. When you are eating in a restaurant, check every burger or other meat. Open it up and make sure there's no pink meat at all to protect yourself and your children from toxo, *E. coli*, and other diseases carried by raw meat.

**NOTE:** Toxoplasmosis can give anybody a "flu," but pregnant women have to be especially careful not to eat rare or raw meat. Toxo is very serious to a fetus. It can cause blindness, retardation, or death.

Other animals besides cats can get toxo in their meat by eating cat poop that's in a grain bin or on grass. This can result in sheep with toxo cysts. Toxo cysts are killed by freezing, but the meat has to be frozen for a very long time at a very low temperature, not in the freezer compartment of your fridge. However, cooking takes care of them quickly and finally.

**SECRETS OF COOKING STRONG- or STRANGE-TASTING MEATS:** Some meat may be objectionably "strong" or "strange" tasting for some eaters: older, uncastrated males, goat and mutton of any age or sex, and all wild meats. There are many ways to moderate or cover such tastes.

1. Any marinade helps.
2. Trim away all fat. This is important because the fat tends to be even stronger-tasting than the meat. Baste and fry instead with cooking oil, margarine, butter, or lard. A roast can be larded with fatty pork strips or basted with sauce to keep it from becoming dry and tough.
3. Also make sure there are no hairs on the meat; hair too carries a strong "off" taste. If you need to clean the meat, do so with a cloth dipped in vinegar. Vinegar helps dissolve clotted blood and pick up stray hairs.
4. It helps to presoak from half an hour to an hour in a solution of salt and/or vinegar.
5. Or precook 15 minutes, covered with water, and then discard water.
6. Wild-meat recipes tend to include rich marinades, stuffings of sliced onions and/or orange halves (discarded after the baking), or tasty stuffings that are served together with the meat.

7. A couple tablespoons of a tart jelly—like currant, barberry, or wild plum—in the gravy or on the plate helps any strong meat. Or serve the meat plain with a fancy fruit ketchup, such as peach. Or use other types of flavorful gravies, sauces, and heavy seasonings in general. Any recipe that involves a barbecue sauce will also camouflage an unfamiliar meat.

8. Another way to soften a strong meat's flavor is to combine the strong meat with a milder one, as in a wild meat/pork sausage combination; with potatoes, as in hash recipes; or with other bland vegetables like cabbage, cauliflower, asparagus, or breaded tomatoes.

**WILD CRITTERS**

Porcupine is one kind of animal my daddy never hunted. He said that was the only kind of meat that a man who was
lost in the forest without a gun had a chance of catching, because they are so slow-moving. He wanted to save them so they'd be plentiful for such a desperate man. In the years since I started this book, I've seen the numbers of various animals fall—and sometimes rise to the nuisance level again! So obey your current hunting laws, because they're carefully tuned to your local situation and needs.

I like wild animals, and I like a certain wildness in people too. I'm bothered by the extent to which writers think they have to write only what editors want, what publishers will print. I think writers have a special function and social obligation to their human community to be on the cutting edge. We need writers with bold new visions—ideas that are controversial or seemingly impossible at first glance yet may map the future. Farsighted writing that challenges the status quo tends by its nature to be unacceptable to Establishment publishing, yet it's essential to society because it articulates options. Some options are radical, some bad; but hidden in the confusion of choices is a new path—perhaps a hitherto unconsidered route, perhaps a revalued treasure of traditional living—that is the best one of all. So much important thinking appears first in small magazines or is self-published. We need to keep the doors open to these voices. And it's terribly important for our freedom of speech that people be able to publish magazines and books without submitting them to government review first, even to get a "copyright" or bar code/ISBN number to facilitate marketing.

The bottom line has to be courage. There's a plaque on my wall that I've treasured for years: "Anybody who says something is impossible is always being interrupted by someone doing it." "Impossible" is merely a relative term. One person's "impossible" is another person's "possible"—if the second person is willing to invest in the project an amount of dedication, time, and effort that the first person couldn't even imagine, much less put forth. Now, back to the topic . . .

Hunting Birds with a Shotgun

Don't! As many as 3,000,000 water birds now die every year from lead poisoning, according to the Nov. 22, 1992, issue of Awake! magazine. Lead poisoning from waterfowl hunting is a tremendous environmental problem. The U.S. Department of the Interior estimates that for every bird that hunters kill, half a pound of lead pellets from their shotguns ends up in the ground and water. Wildlife biologists testing wetlands have discovered as many as 100,000 lead pellets per acre in the top few inches. (Lead fishing weights lost by fishermen litter the bottom of popular fishing areas.)

Waterfowl frequently eat lead pellets during their search for food. In a bird with lead poisoning, the poison reaches the heart, liver, and kidneys 3 to 10 days after it eats the lead; after another week, it is so sick that it enters a coma and soon dies. Bald eagles acquire lead poisoning by swallowing waterfowl that contain lead because they have been shot. At least 120 bald eagles have died from lead poisoning since 1966, and the rate of this type of death is increasing. Since official statistics include only eagles whose carcasses were examined for cause of death, obviously they represent only a small part of the total.

Lead-polluted land is also permanently ruined for agriculture, because any human or animal fodder that grows on it will have a high lead content. People may grow food or fodder there, not knowing of the lead, and thus risk further poisoning. I'd like to see lead-pellet shotguns made illegal. I'm totally serious. They aren't worth the environmental costs. I'd also like to see lead fishing weights made illegal. In fact, just about all uses of lead need to be outlawed. Lead poisoning is currently a worldwide long-term epidemic affecting people of all ages from conception to old age because lead is entering our bodies from our drinking water, air, and food. At best, lead exposure "merely" permanently lowers I.Q. At worst, it causes death.

Preparing Wild Birds: If you do kill a wild bird for food, proceed as you would if it were a domesticated breed. Pick or skin the bird, and then remove the entrails. The bird will pick easiest while it still has as much body heat as possible, before the feathers have had a chance to set tight. See the discussion of ducks in Chapter 9 for details. Cook as you would a domesticated bird. To cook a game bird in a camping setup, you can roast it by turning it on a spit slowly over a campfire, or cook in a slow to moderate Dutch or camper's oven, or (easiest of all) boil to tenderness in a stew. Wild birds are leaner than domesticated ones, and it may help a roasted one to turn it frequently, basting with margarine or a basting sauce.

NOTE: Before you cook a wild bird, consider a moment: what has that bird been eating in these polluted times? Mercury-treated seed grains? Then don't eat it! Fish from waterways polluted with dioxins, heavy metals, or radioactivity? Then don't eat either bird or fish!

Large Wild Mammals

Stay within the hunting limit. Mike and I didn't get any wild meat this last year. We were going to keep the deer on our place as pets, but we got a rude awakening. Somebody came on our place and shot them. The same guy got the buck, the doe, and the fawn. We know because he bragged about it to a friend of ours. Kind of makes you feel that posting your property isn't such a wicked and unsocial thing to do after all!

Be Prepared: To avoid waste (hunting is harvesting of a wild food), be prepared to deal properly with the meat. A good reference about hunting and wild meat is Enjoy Your Game Meat: From Planning the Hunt to Eating the Bounty by Neal Blair and Judy Hosafros (Wyoming Game and Fish Department, 1974). Another one is Getting the Most from Your Game and Fish by Robert Candy.

Start by taking a good sheath knife or a substantial folding knife and a small whetstone. Your folding knife blade must lock in the open position so it can't snap shut on bare knuckles. A belt ax or small hand saw will be handy. There are a number of saws on the market for the hunter. Some fold into the handle; some come in leather sheaths. Pick one of good quality. Elk bones dull a poor-quality saw in a hurry. A small block and tackle hoist can be a real timesaver. Some of these weigh as little as 2 lb. and can hoist an elk. Pack some cheesecloth sacks to put the quarters in. You can buy them at sporting goods stores or make them. Take salt too—not iodized salt but pickling salt—because even if you don't want the hide, you can give it to someone who can use it or sell it to a buyer.

Always carry fire-making equipment or matches in a waterproof container when hunting. Even in wet weather, you can always chop away some of the outside layer of a dead stump or whittle some dry kindling from pitch wood inside the soggy exterior. If you get lost late in the day, don't
stumble around in the dark. Build a fire in a sheltered spot near available wood and make the most of it till daylight.

Wild meat generally has more lean than fat; the big exception is bear in the prehibernation season. And the lean of such animals as deer, elk, antelope, moose, caribou, reindeer, and small game is of greater density than the flesh of domesticated animals, maybe because they get more exercise. The age range is greater too, since domestic animals are almost always butchered in their young prime—except for hamburger-type cows or sausage pigs, whose meat is ground up, so you can't tell its age.

So wild meat may be on the tough side. Another reason for that: more care is generally given to the meat when butchering domestic than when butchering wild. What I mean is, a wild animal may have been running for, say, 2 hours during a peak hunting day as it encounters hunter after hunter. It is then cut down with a whole batch of bullets that hit it in prime meaty places, such as the front shoulder or hind hip. The animal lies for a couple of hours before being gutted, and the gutters forget to remove the testicles. Then it waits another 5 days or so in warmish weather, while the rest of the hunting party has a chance to get "theirs," before being cut up and taken to the freezer. Is it any surprise that the meat may not compare very favorably to beefsteak?

To minimize the meat's wild flavor, hunt early in the season, or else kill a female. In the large game animals, the meat of the males becomes stronger in taste as the mating season advances. Try to avoid handling the musk glands of deer, which are between the hocks and hoofs. Try to avoid killing the animal when it has been running and is very up to it. Gutting, and the gutters forget to remove the testicles. Then halve and quarter and hang up to cool, if you aren't going anywhere for a while. The meat of any antlered game animal is called "venison."

**APPROACHING A DOWNED ANIMAL:** Never assume an animal is dead, even if it appears to be. Approach cautiously with your rifle ready and from a direction that will enable you to stay away from flying hoofs and flaying antlers. Once you are sure the animal is dead, do whatever is necessary to mark the kill as yours, according to the local hunting laws.

**BLEEDING OUT LARGE GAME:** Any large animal—deer, elk, caribou, antelope, moose, etc.—has to be bled out, and thoroughly. Head, neck, and spine shots do not allow enough bleeding. And if the animal has been shot in the chest or abdomen, it probably won't bleed more than a little because, in that case, its blood has already run into those body cavities. So you have to cut the throat as soon as you can to get to a downed animal. Beginners may find it easiest to do a side-to-side cut at the base of the neck. Pros prefer a breastbone to upward cut. Now move the animal to have its head downhill so as much blood as possible can run out the hole you made.

**DEALING WITH PORKY GAME:** This category is boar and bear.

**BOAR.** Butcher boar, a kind of ancient wild pig, by the directions for pigs in Chapter 11. Boars are comparatively lean and, because they get so much more exercise, their meat has a "wild" flavor. So consider using boar meat in wild-meat recipes (see "Recipes for Wild or Gamey-Tasting Meats").

**Bear.** The old-timers cleaned a bear by sticking one hand in his mouth, grabbing his tail with the other, and turning him inside out. Nowadays we lesser mortals have to go the more mundane route of slitting and skinning off the hide—unless you find a bear without his skin. I did once.

As a little girl, I was walking down a little canyon near my home and came upon a large bear lying on the ground. I could see no wound. He appeared to be asleep. The strangest thing, though, was that he was minus his hide. I touched one leg tentatively and uncertainly. He kicked me! Well, I took off for the house yelling. My daddy was there, sharpening his knife blade. I said, "Daddy, Daddy, there's a bear alive in the canyon and he hasn't got his skin on." My daddy laughed. Then he explained that there are reflexes in animals' limbs for a little while even after they are dead.

There are now only 4 or 5 states in the Union where you can kill a bear (or an elk) any more. If you do kill a bear and want to save the fur, turn it on its back and cut the skin in a very straight line from its tail to under its lower jaw. Then cut from the lower inside of one front paw straight across to the lower inside of the other paw. Cut from paw to tail and from paw to tail on the belly side of each of the hind legs. Then peel off the bear's hide. You can gut and quarter it and then take the meat to a custom cutter to be cleaned and cured. Or you can do it yourself, following my directions for pigs in Chapter 11. "Bear grease" means bear lard, and some people declare it's better grease than any other you'll find. You render it the same as pork lard.

You treat bear as you do pork. You can't make jerky out of bear meat because it can carry trichinosis, just like pig meat, and must always be well cooked before eating. A female bear is called a "sow." A young bear is a "shoat." The important thing about female bears and young bears, though, is not their name but their disposition. The only animal that I would tell you outright is aggressive and dangerous is a female bear with cubs. When I was a little girl, we had a man walking around town on one leg, and he was lucky to be walking at all. He made it up a tree with that one leg. Bears have the capacity to keep coming even with a bullet in the brain. You don't want to shoot one unless you're sure it can't get to you before it drops. Don't ever be one of those foolish Yellowstone Park tourist types who tries to get close and photograph that kind of bear.

If you want to thoroughly recreate an early colonial Thanksgiving dessert, make a mince pie with a filling of
bear meat and dried pumpkin. Sweeten it with maple sugar and use a cornmeal crust.

**ROASTED BEAR MEAT #1** Rub a bear roast with sorghum on the top and sides, and roast in a Dutch oven with about 1/2 inch water. This is my favorite way of making plain old pork roast, too.

**ROASTED BEAR MEAT #2** Rub a bear roast with vinegar and then dry with a cloth. Rub with a mixture of bacon grease, 1/4 t. poultry seasoning, 1/2 t. savory salt, 1/2 t. garlic powder, and 1/2 t. salt. Put the meat in your Dutch oven or roaster with a little water. Cover tightly and bake at medium heat until tender. That's if you want to be able to taste everything but the bear.

**TERIYAKI SPARERIBS BARBECUE** From Lane Morgan, who reports that her Alaska friends marinate bear spareribs in teriyaki sauce and then cook them simmered over a fire. The sauce tenderizes the meat and cuts the wild taste. The ribs are less greasy because the fat drips out. “Great dinner!” she says.

**DRESSING DEER, ANTELOPE, ELK (AND GOATS):** These animals are all more or less closely related and similar to butcher. Remove the innards (“dress it”) as soon as possible. Removing all viscera promptly will speed cooling and prevent spoilage so you'll have better-tasting meat. Arrange the animal on its back, hind legs spread. It may help to use a stick, rock, etc. to prop it in the right position. Now you have to cut the critter open from stem to stern, from neck to rear.

**Of Sex and Scent.** In some states, the law requires that sex identification be left attached to the carcass. If you've got that rule, cut around the scrotum or mammary gland and leave that skin attached. Sex organs won't harm the flavor. However, the scent glands may reinforce the wild flavor unless you remove them. They're on the hind legs, right below the “knee” and toward the inside (belly side) of the legs. Pros remove them carefully: secretions still on hair around the openings could get on your hands or knife blade and make your meat smell. In any case, you'll have to cut around the edge of the muscular diaphragm that separates the abdominal cavity from the chest cavity in order to get at the lungs and heart. On an elk or moose, you may well need to use your ax or saw. Carefully reach forward in the chest cavity to cut the windpipe and gullet, which are in front of the lungs. Cutting those will free up the lungs and heart so you can pull them out of the chest cavity. Once all the contents of the chest and abdominal cavities are free, turn the animal on its side. Split the pelvic bone by inserting your knife blade into the seam between the 2 halves of the pelvis, tapping on the end of the handle and then prying downward. Again, on moose or elk, the hand ax may be necessary. Carefully roll out all the intestines, bladder, and genital organs. Also make sure any accumulated blood there is drained away. Slit the muscles holding the windpipe and gullet and pull them out.

**Removing the Edible Organs.** Cut the heart free from its membrane pouch. Carefully cut away the gall bladder from the liver. You'll have to throw away part of the liver to do this without cutting into the gall bladder. Then remove the liver and the 2 kidneys. You may wish to save the sheets of abdominal fat. To get the tongue, cut through the underside of the jaw deep enough so the tongue can be pulled through the opening and cut off near its base. (Don't remove the tongue if you're planning on having the head mounted.) To get the brains, the easiest way to open the skull is with a meat saw, although you can do it with an ax too. A waterproof bag is a good idea for carrying these back to camp or home. Use the organs for camp meat, if you aren't going home right away, since they won't keep as well as the muscle meat. See “Recipes for Wild or Gamey-Tasting Meats” for camp-type recipes for organ meats.

**Cooling the Meat.** Wild meat needs to be cooled quickly to avoid spoiling. If you intend to leave the carcass for a while, arrange it in the shade on some rocks or logs with the cavity propped open so that air can circulate through it and the body heat can dissipate. Throw a few fresh branches over it loosely to keep out birds. If you split the backbone between the shoulders with an ax, the cooling process (especially for moose or elk) will be greatly expedited. In warm weather, skin before cooling and cover the carcass or quarters in cheesecloth or cotton bags to protect it from flies. Avoid cooling in plastic or other materials that do not allow air to circulate; they could cause spoilage.

**SKINNING, QUARTERING, AND PACKING:** First comes a decision: To skin or not to skin? The answer is: It depends. Here are some factors to consider in this judgment call.

**“Yes” to Skinning.** There are practical reasons why you should skin the carcass quickly. In above-freezing weather, the meat will cool much more slowly with the hide on. In below-freezing weather, you want to finish skinning because the more recently the animal has been killed, the easier it is to skin off the hide. You also want to skin before the hide has time to freeze on, which makes it much more difficult to get off. And meat stays fresh better when the air can get to it.

**“No” to Skinning.** Alternate thawing and freezing will reduce meat quality. If the temperatures are fluctuating from day to night, you may want to leave the hide on to keep the meat at a more uniform temperature. If you are going to age the meat, leaving the skin on prevents excessive drying.

**How to Skin.** Hanging up the animal makes skinning it easier. A “skinning knife” has a curved blade, but you can make do with any sharp hunting or butcher knife. Have
some flour or cornmeal handy; if you accidentally cut into the flesh and blood starts to get onto the fur, you can apply flour or meal to the freshly cut areas to stop the blood.

Skinning should be done before the skin is set on firmly. On a warm, freshly killed carcass, the skin can almost always be pulled away, and it takes just a few minutes. The skin on a cold animal must be cut away, and that greatly increases your risk of accidentally getting holes in the hide.

To remove the hide, cut around each of the 4 knee joints. Then slit along the inside of the leg clear up to the center cut from which you took out the viscera. Extend the belly incision on up to the neck just below the lower jaw. Take off the head by cutting completely around the neck, right behind the ears, jaws, and antlers (unless you want to save the head for mounting, in which case the directions are very different and you should come prepared with instructions from your taxidermist as to how he or she wants it done.) Slit the skin on the underside of the tail and then begin cutting the skin from the body. Like mutton, venison has a thin white layer between skin and flesh. You cut through this layer in long easy swipes with a very sharp blade. It helps to have someone pulling the skin taut while you are cutting it loose. If you intend to tan the hide, see the instructions on scraping and caring for the hide in the “Tanning” section.

**Skinning Antelope.** Antelope is a little tricky to skin and dress. The meat can develop a strong, gamey taste if the animal was run hard or was crippled before being killed. Pronghorn antelope should be cleaned and skinned immediately, right on the spot. Remove the entrails first; then skin. Do not get hair on the meat. Hang the carcass to allow air to circulate for at least an hour before you load it up.

**Quartering.** This is necessary with wild game unless you can drive to the carcass. Split the body completely in two along the backbone, working quickly to help cool it and avoid any spoiling. Quarter by cutting between the second and third rib from the rear and the vertebrae. To do this quartering, you need a meat saw or sharp ax. Place the quarters in cheesecloth sacks. If you won't reach home for more than a day or two, salt the hide. Rub the salt all over, more on thicker places, and get into all the corners. Roll the hide and get it to the person who will tan it as soon as you can.

**Packing it Out.** A big buck deer will dress out to about 200–225 lb., an elk to 800 lb. You can usually pack an elk out 2 quarters to 1 horse. You probably need 3 horses for a large moose. Some people bone out the meat to get the weight down. Balance the meat on the horse's back to spare the horse from serious injury. This is no problem as long as you pack the 2 front quarters or the 2 hindquarters from the same animal on one horse. Pack one on each side of the saddle, and fasten them down with a diamond hitch.

If you have to pack the meat yourself, don't drag it. Cut it up into smaller parcels and make several trips carrying it on your back. Until you can get the meat home, keep it as cool as possible. Quartering and hanging it with air circulating around it will help. On the way home your animal is better off on the trunk of the car than over the hood because the engine's heat promotes spoilage.

**SECRETS OF TRIMMING MEAT**

1. Chill meat as much as you can before cutting up. Any meat is easier to cut when it is cold because cold fat is firmer. Wild meat, being so lean, is especially wobbly.
2. It helps to have one person trimming fat, etc., off the cuts as another carves them off.
3. Trim away all fat because wild game fat quickly becomes rancid.
4. Unless you're lucky and the hunter got the animal in the head, wherever the bullet passed through it the meat will be messed up—torn and bloodshot (meat containing hard black bits is “bloodshot”). You must trim out all bloodshot meat, or else throw away the whole piece. Bloodshot meat doesn't look or taste good, and it spoils very easily.
5. Get rid of all the black bits. A well-bled animal shouldn't have too many.
6. If some of the meat has started to spoil, trim off the moldy areas or the parts that don't smell good. Go ahead and wrap and freeze the rest. Such meat, however, must be cooked very promptly and thoroughly upon thawing.
7. On wild meat, you trim away the tough paper-like outer skin from your steaks. You can cut it at each end and just rip it off across the middle.

**Boning Out:** This means removing all the meat from all the bones, period. It's most feasible with a relatively small game animal. But this method, like most “methods,” is rather extreme. We bone out only a few appropriate cuts. You can save the fat for candle or soap making.

**Cutting Up the Hindquarters:** These directions are for deer, elk, antelope, moose, and goat.

**Haunch.** This is the quarter containing the Achilles tendon, by which you were hanging the animal, and the big rear “haunch.” “Haunch” means the whole hind leg of the animal. Cut off the haunch at the hip joint. It begins just below where the ribs end, and you'll have to guess at just the right spot. You'll need your meat saw to get through the bone.
Now cut across the haunch in 2 places to make thirds from top to bottom.

The top (widest) third is your round steak. To make big round steaks, cut right across the grain and through the bone of the entire haunch. An easier way, which avoids having to saw across that bone for every steak, is separating the muscle bundles. The largest bundles are the "top round" and "bottom round" cuts. You can separate these two bundles if you want, and cut across into steaks or leave them attached together and cut into steaks (depending on the size of your animal and your preference). The other muscle bundle is the sirloin. Cut across the grain for your sirloin steaks.

The middle third of the haunch is generally made into a roast. Some people, however, strip it off the bone and make hamburger or jerky out of it. The long, nice strips are good for jerky. The bottom third is generally stripped of meat and the meat put into the hamburger or jerky pile. The bone can be a soup bone.

Ribs and Backstrap. What you have left of the hindquarter is the ribs and backstrap. There are 2 strips of muscle along the backbone. The strip along the outside is the backstrap (tenderloin) and is the choicest, most tender meat in the animal. You can either "bone out" these 2 muscles by cutting them away from the backbone and slicing them into steaks, or you can cut across the backbone for each steak and have both muscles represented in each steak.

If you saved each one out you would have these cuts (using beef terminology), starting from the front end of the animal: club steaks, then T-bone steaks, and finally sirloin steaks. You can see the "T" shaped bone in the T-bone steaks. As a general guide, the first third of the backstrap will be club steaks, the middle third T-bone, and the last third sirloin. Some people make a roast of the last third instead of cutting it up for steaks; to make a roast, just leave it in one piece.

On a small animal such as a deer (a deer has about one-fourth the meat of an elk or cow), all that sawing is not worth the amount of meat you get out of it, so the 2 long muscles are generally boned out. The small inside strip is the one that would be the small piece of meat on the inside of your T-bone steak. If you bone it out, you can slice and make "tips" of it, which are fine floured and fried. You lose a little but not too much on your chop size from the boning-out process. Cut as close to the ribs and backbone as you can to minimize loss. If you decide to bone out the tenderloin, then just cut across it to make the steaks. From a small deer, the steaks are very small but good. Allow 2 or 3 for each person per meal. Some people make a roast of the sirloin instead. If you want 2 roasts, just cut it across the middle.

You can saw across the ribs and backbone to suit yourself for soup bones, spareribs, and dog food. A small deer doesn't make very good spareribs—there is so very little meat with salt and pepper or garlic salt on both sides, and then dip it into flour. Fry quickly over moderate to low heat in a little butter or oil. After 1 side is cooked, turn to brown the other side. Remove the meat from the pan. Thicken the pan drippings with 1 T. (or so) flour. Add water until it is of a suitable gravy consistency, and add 2 T. currant (or other tart) jelly. Season the gravy if your taste buds say it is needed.

A possible problem with wild meat is that its tenderness varies greatly. Tame meat is usually butchered relatively young. But wild meat might be any age—and correspondingly tough or tender. You'll soon know the kind you have and will be able to make cooking adaptations accordingly.

**Tender Ones**

**FRIED WILD MEAT WITH JELLY GRAVY** Sprinkle the meat with salt and pepper or garlic salt on both sides, and then dip it into flour. Fry quickly over moderate to low heat in a little butter or oil. After 1 side is cooked, turn to brown the other side. Remove the meat from the pan. Thicken the pan drippings with 1 T. (or so) flour. Add water until it is of a suitable gravy consistency, and add 2 T. currant (or other tart) jelly. Season the gravy if your taste buds say it is needed.

**WILD STEAK, ORIENTAL** Mix together 1/2 c. cooking oil, 2 chopped garlic cloves, and 2 T. soy sauce. Cut about 1 lb. wild steak into cubes or strips. Let first mixture rest about an hour to get well flavored. Remove and discard seeds from 1 green pepper; then cut it into strips. Chop an onion, add 1 c. chopped celery if you have it, and get ready a couple of fresh tomatoes by slicing into chunks. This is a good one to make near the end of the garden season, when you have this stuff. Now brown the steak bits in your oil mixture; then add green pepper, onion, and celery; and cook about 7 minutes more. Dissolve 1 t. cornstarch in a little water and stir it into the mixture. Salt and pepper to taste. Add a little homemade ketchup or tomato sauce, if you have it; your fresh tomatoes; and a little more water if needed to give the mixture a manageable consistency. Serve with cooked rice.

**WILD MEAT, HAWAIIAN** Cube or cut into strips about 1 lb. wild steak. Shake the meat in a paper bag with some flour until the pieces are all coated. Brown them in enough
butter to do the job. Then add 1/2 c. boiling water, salt to taste, and simmer until tender. Hollow out and slice 2 green peppers. (Optional: add 1/2 c. pineapple chunks.) In a separate pan make a sauce of 2 T. cornstarch, 1/2 c. vinegar, 2 T. soy sauce, 2 T. brown sugar, and 1/2 c. pineapple juice if you are using pineapple or water if you aren’t. When the sauce is thick, pour it over the meat. Cook the entire mixture about 3 more minutes and then serve with rice.

**Tough Ones**

### MUSTARD STEAKS

Brush both sides of 4 good-sized wild steaks with about 2 T. mustard. Sprinkle both sides of the meat with salt and pepper, and then dip both sides in flour. Brown in melted butter in your Dutch oven. Set aside. In a saucepan combine 2 T. brown sugar, 1 t. salt, 2 T. mustard, and a dash each chili powder and cayenne— and, if you have a strong digestive tract, 2 T. Worcestershire sauce, 1/2 c. vinegar, 1/2 c. water, and 1 c. tomato juice or 1/2 c. tomato ketchup and 1/2 c. water. When the sauce seems well mixed, pour it over your meat. Put the lid on the Dutch oven and bake at 350°F until done.

### WILD STEAK, HUNGARIAN

Start out with enough steak for 6 people. Dip it lightly in flour; shake off the excess. Brown in a little fat. Pour into your Dutch oven. Brown several large onions, sliced, in some oil. When they’re cooked to transparency, pour them over the meat. Add 1 t. salt, 1/2 t. paprika, 1/2 c. sour cream, 1/2 c. water, and 1 bay leaf. Bake at 325°F about 2 hours.

### STEAK AND WATER

Brown steaks in 2 T. shortening. Remove meat from pan. Make a gravy by adding 2 T. flour, salt and pepper to taste, and 2 c. water, after your flour has absorbed all the drippings and browned. Return steaks to pan in gravy. Cook, covered, in the oven at 300°F until tender (about 45 minutes).

### ROASTS

1. Usually cook these in a Dutch oven, usually with the lid on, usually at about 350°F but sometimes less, and usually brown the meat in a little fat in a frying pan to just sear and seal the outside before commencing roasting. You can substitute your favorite roasting pan for my Dutch oven. Trim all the fat away from a wild roast before commencing.

   If your meat is from a comparatively old, tough animal, you may prefer a first stage of simmering in a large pan of boiling water, 30 minutes per pound, or until tender. Then drain and finish “roasting.” A quicker way to precook is in your pressure cooker. You may have to cut the roast into several pieces to fit. Pressure-cook for 15 minutes at 15 lb. pressure. Then go ahead and “roast.” It won’t take long after the precooking. Your results will be both delicious and tender.

### WILD Mock HAM

Bake in an airtight cooker like a Dutch oven at 350°F; 30 minutes per pound. When meat is tender, take it out. In a separate container combine 1/2 c. brown sugar, 1 t. mustard, and 1 c. orange or pineapple juice (or available juice of your preference). Score outer layer of roast with knife, and pour juice mixture over it. Stud with cloves. Bake uncovered for an additional half hour, basting frequently with pan juices. Good served hot or cold.

### SPICY OVEN-BAKED WILD MEAT

Combine 1/2 c. flour with 1 t. salt, 1 t. curry powder, 1/2 t. pepper, and 1/2 t. paprika, making sure the seasonings are well distributed in the flour. Cover meat pieces (cubes, tips, small animal parts—whatever you want to cook) on all sides with the flour-seasoning mixture. Fry meat in oil or fat until well browned on all sides. Then move meat to a baking dish, add 1 c. water, cover, and bake an hour. If you like, you can make a gravy before serving by adding flour and water to thicken liquid.

### BARBECUE-SAUCE WILD ROAST

This recipe is good for an entire small animal cooked whole or for a chunk of a bigger one. Cover meat with cold water, add salt, and 1 small hot pepper. Cook over low heat until just tender. Pour off the water; place meat into baking pan. Roast at moderate heat, basting often with barbecue sauce, until it looks done to suit you.

### ONION-SMOTHERED ROAST

Mix together 1/2 c. flour, 1 t. salt, and 1/2 t. pepper. Flour your meat pieces thoroughly in that and then fry them until browned in just enough oil. Move meat to a baking dish. Add 3 large chopped onions, and 2 bay leaves. Bake in a moderate oven until tender.

### WILD ROAST WITH DRESSING

Brown your roast in a little bacon grease or other fat. Sprinkle it with salt and pepper to suit yourself. Bake in a Dutch oven, covered for 2 hours at 300°F (assuming about a 2 1/2-lb. roast). Make about 1 lb. bread crumbs. Combine them in a bowl with 1 1/2 t. sage, 2 eggs, 1/4 c. chopped onion, and 1 bay leaf. Add enough milk to moisten the mixture, and mix it well. Take your roast out of the oven. There will be juice in the bottom of the pan. Skim off any grease floating on top of it as best you can. Then spoon your dressing right down into the meat juice all around the roast. Cover and continue baking at 350°F for 1 hour more. To serve, remove the roast and carve it. Serve the dressing in a separate bowl. This is a favorite of mine.

### COFFEE WILD ROAST

In a wild roast, make slits big enough for sliced onions. Slice 2 onions and fit them into the slits. Make a marinade of 1/2 c. vinegar and 1/2 c. water; pour that over the roast. Marinate overnight in the refrigerator or other cool place. When ready to cook, drain off the marinade, brown roast in bacon fat or other oil, lay a few bacon strips across the top, sprinkle salt and pepper over, and set in your Dutch oven or roaster. Add a mixture of half coffee and half water (about 2 c. of each); keep the lid on your roaster and cook at 350°F until done.

### GREEN PEPPER WILD ROAST

I like this one a lot too. Put your wild roast, a sprinkle of salt and pepper, and 4 chopped garlic cloves (or fewer if you aren’t a garlic lover) into your Dutch oven. Pour in 1 c. water, cover, and cook until done. Remove the seeds from 3 green peppers, cut them into slices, and saute about 10 minutes in a little cooking oil. Add some of your homemade tomato ketchup, canned tomatoes, or tomato juice if you like the flavor. Pour the green pepper sauce over the meat; carve and serve.

### HERBED WILD ROAST

Combine 1/2 c. flour, 2 t. marjoram, 1 t. thyme, and 2 t. rosemary, and 1 cut-up clove garlic. Rub your wild roast with a little cooking oil. Sprinkle salt and pepper on it; then apply your herb mixture to it. Put the roast into your Dutch oven; add 1 c. water and 1 c. apple juice. Bake, basting occasionally, until done.

### MOOSE POT ROAST WITH MUSTARD AND TARRAGON

From cookbook author Lane Morgan! Marinate meat a few hours in red wine, raspberry or blueberry vinegar (if available), and a little soy sauce. Brown meat in a little oil. Then add a few chopped garlic cloves, a chopped onion, and 2
Small Wild Mammals

Lane Morgan suggests that I “mention the animals that are most realistic for hunting in most areas of the country—squirrels and raccoons and possum, I suppose. We could certainly use fewer possums around our place.” The wise and knowledgeable Gene Logsdon, one of my favorite authors, wrote in Gene Logsdon’s Practical Skills (published by Rodale Press, listed in the book source list in Chapter 1): “Eating wild rabbits, squirrels, groundhogs, and raccoons seems distasteful, even to those who are gulping down steak and hamburger every day. As civilization ‘advances,’ that part of its society that eats meat tends to restrict itself to fewer and fewer species of animals, which is quite wasteful. Earlier societies ate many more kinds of meat than we do today: in medieval Europe all manner of birds and small game were kept in captivity for meat, occupying various niches in the food web.” So here are some tips to help you expand your food resources if you so choose.

HEALTH RULES FOR SMALL-ANIMAL EATERS

1. Never eat a small animal that is already dead.
2. Don’t hunt an animal that isn’t acting lively.
3. Even if you personally kill the animal, if, once you have a chance to inspect it more closely, it looks somehow in poor health, don’t even touch it. (When in doubt, throw it out.)
4. Wild rabbits and some other small mammals may be sick with infections that can be contracted by the hunter (less likely during winter). Don’t cut yourself while cleaning such animals. It’s recommended that you wear rubber gloves when skinning or cleaning any small game animal, especially wild rabbits.
5. Check the animal’s liver. White cyst-like spots in the liver, pea-size or smaller, indicate tularemia or coccidiosis. If you have handled an infected carcass, clean hands thoroughly with strong soap and discard the meat. Do not eat the meat of animals with white liver spots.

KERNELS: Some small mammals have small waxy or reddish glands, like kernels, situated under the forelegs, along the lower part of the backbone, and/or under the lower part of the abdomen. They are often pulled away with the skin. If not, they must be carefully cut out so as to be removed intact because if one gets cut, it will give a strong, musky taste to the meat.

DRESSING: Small game should be dressed as soon as possible and allowed to cool thoroughly. Remove the entrails and let the blood drain. To clean a rabbit in the field, make an incision down the belly from the vent to the breastbone, taking care not to puncture the intestines or stomach. Grasp the front feet and the head in one hand and swing the rabbit sharply downward, snapping the entrails out of the body cavity. Then reach into the chest and pull out the lungs, heart, and liver. Cut off the head and wipe the body cavity out with a cloth or dry grass.
**Special Small-Mammal Tips**

Beaver: Cook beaver tail in the skin. Beaver tail meat is gelatinous. Use like ham with baked beans or pea soup.

Muskrat: Remove scent glands situated under both hind and forelegs.

Opossum: When skinning, remove scent glands in the small of the back and inside the forelegs.

Porcupine: Skin by starting with the unquilled belly.

Rabbit, Wild: Wear gloves. Remove glands from under forearms.

Raccoon: Carefully remove the brown, bean-shaped kernels under each front leg and on both sides of its backbone, similar to opossum.

Woodchuck: As part of the skinning process, carefully remove the small red scent glands located between the forelegs and the body. Because of its exceptionally strong flavor, boil woodchuck for 20 minutes in salted water (then discard the water) before using it in any recipe.

**Basic Small-Mammal Skinning:** These directions are for when you want to use the skin. Any small game—muskrat, wild (or domestic) rabbit, squirrel, opossum, porcupine—may be dealt with as follows. Cut off the head, tail, and forepaws. Hang up the torso by the hind legs. Have those hind legs separated far enough so you’ll be able to easily work between them. Cut on the backside of the leg in a straight line from the hock on one side up to the tail hole. Do the same thing on the other side. Now cut the skin from foreleg to the neck opening on one side, and then do the same on the other side. Starting from the hind end of the animal, now peel off the skin. Using pliers can help you get a better grip on the skin so you can pull hard enough to get it off. Squirrels have tough skin that clings more.

After cutting through the tail (keeping it attached to the back of the skin) and slitting the skin from the base of the tail down the back side of each hind leg and around the hocks, peel the skin off the back legs. Now stand on the tail and pull upward on both of the squirrel’s hind legs. This may take a little practice, but eventually you’ll be able to peel off the hide over the head and front feet. For more info and suitable recipes, see the section on rabbits in Chapter 11. You can leave the skin on a wild rabbit until you cook or freeze it.

**Cooking a Small Mammal:** Any small game may be cooked whole or cut into pieces. Use in wild-meat recipes, rabbit recipes, chicken recipes, or any meat recipes that you feel like trying it in. See “Recipes for Wild or Gamey-Tasting Meats” for more ideas.

**Brunswick Stew** This is a classic old-time small animal dish. Start with 2 lb. meat; a medium-sized bird, a large rabbit, or several squirrels will do it. Brown the meat in fat along with 1 chopped onion. Cover and boil with water or bake until meat is tender. Then add water (if more is needed), corn, tomatoes, and beans. There are infinite variations: the corn can be canned or on the ear, the beans can be lima or green, the tomatoes can be fresh or canned. Season to taste with salt and pepper. Eat when the vegetables are cooked.

**Snail, Snake, Turtle, and Frog**

Here’s how to prepare these critters that are neither bird, mammal, nor fish.

**Snail:** There’s a lot to know about collecting and eating snails. Some are not good to eat. Some need special treatment. There are land and marine snails too, and each are different. California is good snail hunting country. Here’s the necessary info (thanks to the Division of Agricultural Sciences, U. of California) for preparing the edible European brown snail or brown garden snail (*Helis aspersa*), which is called “escargot” in French but is the same as the common garden snail considered a pest in the gardens and yards of California. Also known in France as the *petit gris* or vineyard snail, it was probably first brought to the North American continent around 1850. Another edible snail found in some parts of California is the white Spanish or “milk” snail (*Otala lactea*), which is preferred by many people of southern European stock. (Ask an Italian!)

Snails have been used as food throughout the world for centuries. Edible types can be cultivated in cages placed in dooryards, basements, and even in dwellings. Snails are close relatives of the abalone, a sea snail that’s also a table favorite. But the U.S. escargot is generally thought of as a garden nuisance rather than as a free, low-calorie meat crop (about 90 calories per 100 grams [3.5 oz.] of snail meat) that’s also rich in protein and minerals. It would be much better to harvest and use snails for food than to poison them.

**Harvesting.** The brown garden snail (escargot) is about 1 to 1½ inches in diameter and ½ inch wide when mature. Mature snails are the best for cooking—there is more and tastier meat, and the shells are easier to get off. Immature snail shells are thin and hard to work with.

NOTE: Don’t collect snails in areas where poisons have been used for snail control. Instead, water down the area thoroughly and wait at least 6 weeks before collecting snails.

Snail hunting is best about 2 hours after dark because snails are night creatures. Take only moving snails: that’s a sign of good health. Light watering in the late afternoon before your hunt helps bring them out of hiding. You may be able to harvest them more easily during dry weather, when they seal themselves to any surface available; in citrus groves, for example, tree trunks are often covered with hundreds of snails.
**Snail Recipes**

**SNAILS IN TOMATO SAUCE** Saute 1 chopped medium onion, 2 crushed cloves of garlic, and ½ c. chopped bell pepper in 2 T. oil. Add 1 lb. canned tomatoes, salt and pepper to taste, and simmer until bell pepper is tender and flavors are blended. Add 1 pt. cleaned and blanched snail meat for 10 minutes. Serve over hot toast wedges, hot cooked rice, or hot noodles.

**BAKED SNAILS** Simmer cleaned, blanched snail meat for 10 minutes in water seasoned as desired with onion, garlic, allspice, bay leaf, etc. Toss cooked snail meat in melted butter or margarine and roll in bread or cracker crumbs seasoned with salt, pepper, and garlic powder. Place in greased shallow pan and bake in a hot oven until browned. Sprinkle with lemon juice before serving.

**STUFFED SNAIL SHELLS** Simmer cleaned, blanched snail meat in salted water until tender. Chop snail meat, mix with minced garlic, and saute in olive oil or margarine about 5 minutes. Stuff cleaned shells with the chopped, seasoned meat. Seal shell opening with garlic butter. Place under broiler for a few minutes until butter bubbles. Serve immediately.

**FRIED SNAILS** Simmer cleaned, blanched snail meat for 10 minutes in water seasoned as desired with salt, bay leaf, parsley, thyme, allspice, etc. Roll cooked snail meat in fine cracker or bread crumbs seasoned with salt, pepper, and garlic powder. Fry in oil until browned, as you would fried oysters. Sprinkle with lemon juice to serve. These may be served as an entree or, pierced with toothpicks, as hors d'oeuvres.

**SNAILS IN WINE SAUCE** Combine in a casserole dish 18 cleaned and blanched snails, 2 diced slices of bacon, 9 small boiling onions or ½ c. chopped onion, 1 crushed clove garlic, 1 T. minced parsley, a pinch thyme, ¼ t. pepper, and 1 c. red wine or grape juice. Cover and bake 1 hour in a slow oven (275°F). Just before serving, thicken with a butter and flour mixture and serve over crisp toast wedges or croutons. Serves only 3 people.

**SNAILS IN GARLIC BUTTER** Start by creaming together until thoroughly blended 1 crushed large clove garlic, ½ c. butter or margarine, 3 T. finely chopped parsley, 2 T. finely minced green onions with tops, ¼ t. salt, and ½ t. pepper.

**SNAKE/EEL:** These instructions are for snake, but you can prepare eel the same way. Kill the snake by cutting off its head. If it's a poisonous snake, be careful not to touch the fangs, since they contain poison that can enter the bloodstream through a cut or scratch in your skin. There is no poison in the meat, which is typically very white and tender. To skin the snake, nail it down or have someone hold it by the front end with a pair of pliers. Peel off the skin as you would peel a banana. Cut open the body and take out the innards. Cut the skinned meat into 2-5-inch portions. You can split them down the backbone to make them lie flat.

**FRIED SNAKE** Dip pieces into beaten egg. Roll in seasoned flour (garlic, salt, pepper) or cracker crumbs. Pan-fry or deep-fat-fry the snake. Or wrap to keep from drying out, and bake.

**TURTLE:** Freshwater snapping turtles are good eating but dangerous to catch. Grip the shell behind the head, so you can't get bitten. Or get it biting on a stick and then cut off its head with an ax. Let it hang head downward after bleeding until bled out. Cut off all the claws. Then skin the hide down to the legs, which you cut off at the joint. Small turtles can be cooked in the shell until the meat cooks free. Another school of turtle cuisine prefers to proceed by dropping the live turtle into a pan of boiling water, cooking it for about 10 minutes, and then moving it to ice-cold water for 10 more minutes. After this treatment, it will be possible to rub the skin from head, tail, and legs.

Whether you skin or boil your turtle, the next step is the same: you cut through the shell part connecting top and bottom shells. You can use a sharp knife if you have a sharpener, but you'll need a saw or ax for a tougher-shelled turtle. Then pry off the bottom shell. Once the shell is off, you can easily remove the innards. After you get the turtle shelled and cleaned, cook it whole, cut it into quarters, or cut it up as you would chicken (depending on its size and the size of your cooking pans).

There's a good section on the diamondback terrapin in Gene Logsdon's Getting Food from Water.
DORIS’S TURTLE. Soak turtle meat 8 hours in cold salt water (important). Flour it in a mixture of unbleached white flour, salt, and pepper; brown in a frying pan; and bake 4 hours in a slow oven. Or, after browning, add 2 sliced onions and enough water to cover; and simmer until tender. Make gravy with pan juices and serve with mashed potatoes. For gourmet or regular chicken or rabbit recipe.

NOTE: If you want to store meat in your freezer a long time, keep in mind that unsalted, unseasoned, unground meat keeps the longest and best. Gone are the days when smoking, salting, and canning were the only alternatives to eating meat as soon as it was slaughtered. Freezing is perhaps the best way to preserve meat. It has virtually no effect on flavor or texture and gives you the convenience of having a variety of fresh meats in all seasons. Freezing won’t keep meat forever but, estimating conservatively, at 0°F beef and lamb can be stored up to 9 months, veal keeps for 6 months, and ground meats and pork are good for 4 months. Some think that several weeks of freezing has a tenderizing effect, but a tough steak is pretty much always going to be a tough steak. Plan ahead for your freezing needs. Despite the number of home freezers that are crammed with meats and animal products, the home freezer was not designed to quickly freeze hundreds of pounds of meat at a time. If you are butchering that much meat, I would advise you to get a freezer storage locker and just keep enough meat at home for a week’s meals. Or else butcher during very cold weather and let nature help with the quick freezing.

WRAPPING AND FREEZING MEAT: Immediately after cutting, meat must be properly wrapped, quickly frozen, and stored at 0°F. You’ll want to freeze the meat at −10°F or lower, if possible. Put in only the amount of meat that will freeze in 24 hours, and allow ample air circulation by not overpacking the freezer. “Proper wrapping” means using moisture-proof wrap, such as heavily waxed freezer paper, and wrapping meat closely in order to keep out as much air as possible. Air in your package can result in freezer burn and rancidity of the fat.

Freezer Paper. It is shiny on one side, plain on the other. Have ready a pile of sheets of your freezer paper. To cut across the big roll of butcher paper, take a few good snips with your sharp scissors. Then, holding the paper firmly, just push the scissors on across, and it will cut like a razor. An even faster way is to measure out the length of paper needed. Then place the rolled paper on the edge of the kitchen counter or tabletop and pull the paper across the table edge. It will tear straight across.

FROG: The front and hind legs of bullfrogs, leopard frogs, and green marsh frogs are all edible; the rest is discarded. In Oregon the bullfrog is classified as a game fish, and there’s a specific bag limit of so many per day. To prepare frog’s legs, cut off the legs, remove the feet, and peel off the skin.

GOURMET FRIED FROG’S LEGS Season the legs with salt, pepper, and lemon juice. Dip legs into beaten egg and then into crumbs of flour. They will fry very quickly—about 3 minutes in deep fat (a wire frying basket preserves their crust). If you are pan-frying them, turn the heat low and cook 5 to 10 minutes, turning as needed, until the meat separates easily from the bones. You may substitute frog’s legs in any gourmet or regular chicken or rabbit recipe.

WRAPPING PROCEDURE. Figure out how many steaks or chops your family needs per meal, and wrap just that number into each package. Place 2 layers of butcher paper or ordinary waxed paper between the individual steaks or chops. That way they’ll come apart easily when you need them. Also figure out how much stew meat and how many pounds of ground meat you should put in a package. Ground meat can be stored in rolls, blocks, or ready-to-cook patties, with 2 layers of paper between. You can season meat before you freeze it, but if you expect to keep it frozen longer than 2 weeks, wait to salt it until after you thaw it. Put the meat on the shiny side of the paper—that’s to keep it from sticking and from soaking the paper. Put the meat in the center of the sheet, a little nearer one corner. Fold that corner over the meat, fold in both sides, and roll the meat over and over until the paper is used up. Fasten the loose end with a strip of freezer tape. (Freezer tape is needed because regular tape doesn’t hold well under freezing temperatures.) Write on the package the kind of animal (elk, beef, or whatever), the kind of cut (steak, stew, or the like), and the date.

Here is a way of double-wrapping meat that some people use. We don’t because we’re frugal of paper and use up the meat relatively quickly, but for an excellent wrapping method that pushes out the air and protects your meat from freezer burn over the long term, do this:
1. In center of paper, put enough meat for one meal.
2. Wipe hands clean.
3. Bring paper tops together and fold over. Tuck under ends as if wrapping a gift.
5. Tape it closed.
6. Write on the outside what is inside and how many of them.

**ABOUT FREEZING AND TRICHINAE:** Does freezing kill parasites? Yes, if the meat is frozen long enough—and at a sufficiently cold temperature. The kind of parasite that is hardest to kill by freezing is *trichinella*, which may be in bear or pork meat. The "Freezing Temp. and Time to Destroy Trichinella" table shows how to kill it by freezing. But trichinosis can always be avoided by cooking meat, especially pork and most especially bear, to an internal temperature that destroys the trichinella parasites. Fully cook to the point where there is no pink left at all!

**THAWING MEAT:** You can thaw small amounts of frozen meat in various ways: at room temperature, in the refrigerator, at a low temperature in the oven or the cooking pot, or in the microwave. At room temperature, thawing 1 lb. meat takes 2 to 3 hours; in the refrigerator, 5 to 8 hours. Large slabs of meat should be thawed in the refrigerator.

**Canning**

My mother canned a lot of meat when I was a little girl, and one of my most pleasant childhood memories is of the taste of her canned venison stew. You can can any kind of meat. Chicken and rabbit may be canned on the bone, but all the bigger meats, of course, are cut away from the bone before canning. Canning is a good way to handle tough cuts because they get cooked tender in the process. Can only fresh meat that was chilled immediately after killing and kept chilled until canning. Don't can any meat that has turned dark or smells like it's starting to spoil!

See the canning directions in Chapter 7 for info about supplies and safe methods.

**PREPARING**

**Large Pieces of Meat.** Chill the fresh meat immediately after slaughtering at 40°F or below (but don't freeze it, or you lose quality). You can hold the chilled meat for several days or can it as soon as the body heat is gone. Don't wash meat; if needed, just wipe the outside with a damp, clean cloth.

**Frozen Meat.** Canning frozen meat is a second-best option but if you have to, it can be done. Don't thaw it. Just cut into pieces with a saw and soften them in boiling water until they are soft enough to pack in jars. Cutting across the grain, remove most of the fat and reduce the meat to pieces that fit into the jars. Smaller, less tender cuts should be canned separately for stews and casseroles. Bones simmered in water make fine broth both for canning and for soups.

**Strips, Cubes, or Chunks of Meat.** Choose quality chilled meat. Remove excess fat. Soak strong-flavored wild meats for 30 minutes to an hour in brine water containing 1 T. salt per quart. Rinse. Remove large bones. Then hot-pack or raw-pack.

**PACKING MEAT IN JARS:** You can either raw-pack or hot-pack.

**NOTE:** Always leave 1-inch free space ("headspace") at the top of each jar to assure a good seal.

**Raw Pack.** Add 1 t. salt per quart to the jar, if desired. Pack raw meat loosely in clean hot jars, without adding any liquid. Wipe the sealing edge dry.

**Hot Pack:** Precook meat until rare by roasting, stewing, or browning in a small amount of fat. To brown, just place the meat in a large, shallow pan with a little water. Cover and heat until it is medium done (the pink is gone from the inside). Add 1 t. salt per quart, if desired. Loosely pack hot meat in jars with the juice, or add about 4 T. broth, water, or tomato juice (tomato juice is especially good with wild game) per quart jar. You don't need much liquid, since canning cooks more out of the meat.

**PROCESSING:** Pressure-can only. Place lids on jars and process pints 1 1/4 hours, quarts 1 1/2 hours. Process at 10 lb. pressure (weighted gauge) or 11 lb. pressure (dial gauge). Increase pressure for higher elevations according to the "Altitude Adjustments for Pressure Canning" table. Consult your pressure-canner manual for specific meat-canning directions. Don't underprocess meat!

**USING:** When using meats you have canned, always make sure the seal is good (listen for a rush of air, similar to the sound when you open a sealed coffee can). If you don't hear that sound, or if there is dryness, discoloration, or a bad smell, throw away the meat.

**OTHER CANNED-MEAT VARIATIONS**

**Ground or Chopped Meat.** This recipe is good for bear, beef, lamb, pork, sausage, veal, venison, etc. Use fresh, chilled meat. With venison, add 1 part high-quality pork fat to 3 or 4 parts venison before grinding. Use freshly made sausage, seasoned with salt and cayenne pepper (sage may cause a bitter off-flavor). You can add additional spices when you cook the meat for serving. Use 1/4 lean meat to 1/4 fat. Shape chopped meat into patties or balls or cut cased sausage into 3–4-inch links. Cook until lightly browned. Ground meat may be sauteed without shaping. Remove excess fat. Hot-pack only; fill jars with pieces and add boiling meat broth, tomato juice, or water, leaving 1-inch head-space. Add 1 t. salt per quart to the jars, if desired. Pres-
Add sufficient broth to cover. Boil 5 minutes. Pack jars half-

Canned Soup Stock. A way to keep from wasting the bones is to boil them up for a soup stock and can that. Soup is a great thing to have on hand for general cooking purposes. Cook your bones, chicken, etc., until tender in lightly salted water. Then chill. Remove fat and bones. Keep the meat and sediment. Reheat and pour your boiling soup into jars. Don't use burned pieces or bones from pork, smoked or corned meats, or fatty lamb to make stock. You can also freeze your stock, in which case you can lift the frozen fat from the top and have very lean stock. Before canning your meat or soup stock, season it with salt, a few vegetables and onion, celery leaves, bay leaf, or whatever you like. Hot-pack. Adjust lids and pressure-can using "Processing" directions.

Variable Vegetable and Meat Soup. For this soup, you use a mixture of vegetables, dried beans or peas, meat or poultry, and broth. Select, wash, and prepare dried beans or peas, meat, and vegetables as follows. Dried beans or peas: For each cup, add 3 c. water. Boil 2 minutes, remove from heat, and soak one hour. Reheat to boiling; drain. Meat: Cover with water and cook until tender. Cool and remove bones. Vegetables: Simmer several minutes until barely cooked. Broth: Meat broth, canned tomatoes, water, or a combination may be used. Season to taste. Do not add flour, cornstarch, or any other thickening agent.

Combine meat, vegetables, and drained beans or peas. Add sufficient broth to cover. Boil 5 minutes. Pack jars half-full with hot soup mixture. Add more hot broth to fill jar, leaving 1-inch headspace. Adjust lids and pressure-can using "Processing" directions.

Basic Canned Meat Stew. Cut up about 5 lb. meat (beef, venison, chicken) into about 1/2-inch cubes. If you wish, brown in a little fat in your frying pan. Add 1/2 gal. chunked carrots, 1 qt. chunked onion, and 3 qt. peeled potato chunks. Add 1-2 T. salt, and pepper or other seasonings to taste. Mix together; add boiling water and heat until food is heated through. Pack hot into hot jars. Allow 1-inch headspace. Put lids on and pressure-can using "Processing" directions.

Wild Meats. Use the methods in this section, but soak the meat in a brine solution for 30 minutes to an hour before placing it in jars.

HOME-CANNED MEAT SANDWICH Open jar. Take out meat. Slice meat. Lay on bread. Add mustard, mayonnaise, and/or sliced pickle.

ALMOST INSTANT CANNED BEEF DINNER Cook 1 lb. rice. Open a jar of canned beef (or other meat). Add barbecue sauce. Heat. Serve beef sauce over the rice.

Drying

There are 2 basic ways to dry meat. The modern way is to precook, cube, and dry by sun, oven, or dehydrator. The other way—drying thin strips of raw meat, combined with salting—produces jerky.

MODERN MEAT DRYING: Prepare the meat by trimming off all the fat, boiling it until it is tender (or pressure-cooking it for 20 minutes at 1.5 lb. pressure), and cooling. Cut into fairly small cubes and spread on trays. Chunks larger than 1/2 inch square may not dry thoroughly. Dried meat is about two-thirds its original size.

Reconstituting. Pour boiling water over dried meat cubes and then simmer them for 45 minutes to return them to a tender eating consistency.

Heat Sources. You can dry it in the sun if the weather cooperates. Just place trays of cooked meat cubes in a well-ventilated place, covered to protect from insects, where the sun will shine directly on them. It may take 2 or 3 days to get the cubes hard and dry to the center. Turn the cubes several times to get all sides dry. You can also use a commercial dehydrator, a homemade dehydrator, or your oven if you have good control over the lower temperatures. The method for all these devices is the same: keep the temperature at 140°F for the first 4-6 hours, and turn and stir the cubes frequently; then reduce the temperature to 130°F and continue at that heat until the cubes are hard and dry.

Storage. Keep in an airtight jar. Remember that each time you open the jar, moisture in the air gets in. Dried meats, especially jerky, keep only a short time at room temperature because any fat on the meat will turn rancid.

JERKING: Indian- and pioneer-style dried meat is called "jerky." In this case, strips of raw meat are seasoned in a salt-and-pepper brine and dried (or smoked). Some Indian tribes soaked meat in sea water to salt it before drying. Or they hung strips over a slow-burning fire to smoke-dry it.

Jerky is a homemade snack that anyone can enjoy. It's tasty and nourishing cold, and it can be cooked into stews. I send Grandpa Emery a big jar of jerky with a red ribbon around it at Christmas because he really likes that kind of thing. It's good for company. But like many other old-fashioned arts, you have to practice a couple of times to get comfortable with the procedures and to find out just how dry and how spicy your family likes its jerky. Modern commercial jerky is so heavily treated with seasonings and preservatives that trying to eat it as a basic food would make you sick. Meat jerked to use as a basic food should be
cut in very thin strips, prepared without any salt or spices, and dried in the sun a couple of days. Good to eat, snack on, and use in stews and soups. Freezing is the safest way to store it.

Meats to Use. The original jerky was made of unsalted raw beef, but you can make jerky from other raw meats as long as they don’t carry parasites. But so many meats are at risk for carrying parasites that beef, deer, elk, or moose are basically the only choices you have. Use lean red meat. You can jerk any well-cooked meat. Cooked turkey and chicken make tasty jerky. Veteran meat jerkers use the poorest meat for sausage and better cuts such as the loin and round steak for jerking. Frozen meat can be thawed and jerked at any time in its locker life, if it was put into the locker fairly promptly in the first place. About 5 lb. raw meat yields 1 lb. jerky.

Preparing Meat for Jerking. First remove all fat, bone, and visible connective tissue. Cut the remainder into strips about 5 inches long, 1 inch wide, and 1/2 inch or less thick. (Or 6 inches long and 1/4 inch across, or 9 inches long, or whatever you like—but remember that any piece thicker than 1/2 inch will be hard to get dry.) Cut lengthwise along the muscle, not against the grain, to make the long strips. Partially frozen meat will cut more easily into proper-shaped slices. Some cooks then parboil the strips for 13 to 30 seconds, just long enough for them to change color. Some people then marinate the strips.

Seasoning. After the strips are cut but before they are dried, you season them. There are as many possible ways to do this as there are recipes for jerky, and really, they all work okay. You’ll probably experiment. Mike and I never have agreed about it. The simplest method of “seasoning” is to dip the meat into salted (not iodized) water, but people usually want a stronger flavor. Some people use soy sauce or Worcestershire sauce as a marinade. You can soak the meat in a seasoned brine for 24 hours; then rinse briefly and hang up to dry. Or else rub or pound the seasoning in by hand, let the seasoned meat rest a few hours, and then rinse it off under the faucet. Jerked meat usually takes more seasoning than you might think because the heat of the drying process weakens the spices. Sugar, allspice, oregano, marjoram, basil, thyme, garlic powder, and Tabasco are all possibilities. Some people, when making oven-dried jerky rather than smoked jerky, fake it with that store stuff called liquid smoke.

Here are a few seasoning recipes to get you started.

- **PURE SALT BRINE** Make a brine of 1/2 to 1 1/2 lb. pickling salt in 1 gal. water. Proceed as below.

- **SWEET BRINE** Dissolve 1 lb. pickling salt, 1 lb. brown sugar, 1 t. ground allspice, and 2 T. black pepper in 1 gal. water. Use a granite canner, crock, or plastic bucket. Soak the jerky strips in the brine for 12 hours. Weight the meat with a plate and a quart jar of water on top of the plate so that the liquid stays over it. Then rinse off in clear water. My husband prefers this recipe, but I think it is very strong. To weaken it, leave the meat in the seasoned brine a shorter time. Also, marinated meat is likely to take longer to dry than dry-seasoned meat.

- **FANCY FLAVOR** Combine 1/4 t. pepper, 1/4 t. salt, 1 t. lemon juice, and 1/2 c. soy sauce. Marinate the meat in the mixture 1 hour or longer, turning occasionally.

- **FALSE SMOKED JERKY** In a bowl, combine 1 c. soy sauce, 1/4 c. brown sugar, and a few drops of liquid smoke for your dip.

- **TAMARI MARINADE** Mix 1 t. ground black pepper, 8 T. tamarind (or other soy sauce), 16 crushed cloves garlic, and 4 t. wine vinegar with enough water to cover 2 lb. sliced meat. Soak meat for 4 to 6 hours in the refrigerator.

- **AN EASY DRY METHOD** Have ready a suitable-sized granite canner, crock, or plastic bucket. Sprinkle the bottom with salt, pepper, garlic powder, and brown sugar. Put in a layer of meat and sprinkle again. Put in another layer, and so on until you are done. Place the container in the refrigerator or some cool place and let rest 18 hours. Then remove, drain the meat thoroughly of the extracted juice, and proceed to dry it. For a mild jerky, rinse the meat before drying it. This is my favorite recipe. It makes a comparatively sweet jerky.

- **ANOTHER DRY METHOD** Lay the meat strips on a towel. Mix thoroughly 1/2 c. brown (or white) sugar, 1/4 c. salt, and 1 t. crushed black pepper. Or use 1/2 c. salt and 1/2 c. brown sugar. Rub in the seasoning. Juice will be coming out. Turn the strips over and repeat on the other side. Some people do this on a wooden board and pound it in. Roll the strips in a damp (wet and then wring out) towel and leave them in the refrigerator for 8 hours. Take them out of the towel. Rinse each piece thoroughly under running water. Lay on a dry towel for 2 or 3 hours.

**Drying:** After the strips of meat are seasoned, they are ready to dry. This can be done “in the field,” by the heat of the sun during the day and the smoke of your campfire by night; in your smokehouse; or in your oven, depending on your preference and facilities. Just exactly how dry you want the jerky is also a matter of preference. For simple food preservation, the dryer the better, but the jerky should be dark, fibrous-looking, and slightly flexible but not brittle enough to break apart when bent. You can stew the jerky to eat it, but people usually make it for smoking and plan to use it up soon, so they don’t dry it clear out. As a snack it’s nicer with some moisture left in. If some moisture is left, you’ll have to keep it stored in the refrigerator. If you get your jerky too dry to suit you, you can wrap it in a damp towel and keep it in a tightly lidded gallon jar in the refrigerator to recover a little moisture.

**In the Field.** The meat strips can be spread on rocks or bushes on a hot day. If insects are a problem, you can cover the meat with a fine-mesh cloth, or build a smudge fire, or stand there waving your arms all day, praying for a wind. If the weather changes to rain before you’re done, you’ll have to take your meat indoors and wait until the sun shines again to finish. It will take about 3 days to do it this way, more or less, depending on the dryness and heat of your weather.

**Wood Stove.** Drying meat strips over a wood stove is a fine method for wintertime, when you use the stove a lot. Just run wires like clotheslines above the stove, so the meat can be suspended in the hot air around and above the stove. The little metal fasteners sold for hanging Christmas ornaments work fine for fastening a strip of jerky to a clothes hanger or wire.

**ROBERTS OVEN-DRIED JERKY** This is for lean cuts of beef, cooked ham, venison, chicken, or turkey. Trim off all fat and connective tissue. Cut 1/2–2 lb. meat into thin slices. In a bowl, combine 1/4 c. soy sauce, 1 T. Worcestershire, 1/4 t. pep-
per, \( \frac{1}{4} \) t. garlic powder, \( \frac{1}{2} \) t. onion powder, and \( \frac{1}{2} \) t. hickory smoke-flavored salt. Stir until the seasonings are well mixed; then add meat and make sure all surfaces are coated with the seasonings. Cover and let stand at least 1 hour. Shake off excess liquid. Arrange strips close, but not touching, on oven racks or cake racks set in shallow baking pans. Dry at 150–200°F until meat turns brown, feels hard, and is dry to the touch. Poultry will take about 5 hours; beef and venison, 4 to 7 hours. Pat off beads of oil, cool, and store in airtight containers or plastic bags in refrigerator. Makes about \( \frac{1}{2} \) lb jerky.

DEHYDRATOR JERKY Place meat strips on trays without overlapping. Dry 4 hours at 140°F. Rotate the trays and turn the strips over. Continue drying for another 6 to 8 hours. Place aluminum foil or some such below the trays to catch the drippings.

MICROWAVED JERKY This recipe is from the National Live Stock and Meat Board, which warns that microwaved jerky does not have the same long-keeping qualities of traditionally prepared jerky but will keep 4 weeks or more. Prepare your jerky as usual, cutting lengthwise with the grain into \( \frac{1}{8} \)-inch-thick strips. Mix thoroughly together 3 t. salt, 1 t. garlic powder, \( \frac{1}{2} \) t. onion powder, and \( \frac{1}{8} \) t. black pepper. Sprinkle seasoning over strips and mix in order to distribute spices as equally as possible. Arrange a load of strips flat and close together on a microwave-safe bacon rack, and cover with wax paper. Microwave on low for 22 minutes (strips keep better and dry more evenly when cooked at “low” temperature rather than at a higher setting). Now turn strips over and redistribute the driest ones to the center. Rotate rack a half turn and microwave on low again for another 22 minutes, or until jerky is dry but slightly pliable. Take out the finished jerky and repeat the same procedure with the rest of the strips until you finish them all. Let meat dry still more in open air for 24 hours before storing it in a covered container. Store in an air-tight jar or sealed plastic bag (or frozen for long-term storage).

STORING JERKY: For long-term storage, jerky that’s completely dry will keep very well if stored in an airtight container. I use quart jars. Just screw the lid on tight. Salt and sugar have the same preservative effect in jerky as they do in old-fashioned home-cured hams and bacon. The dryer and more heavily seasoned the jerky, the better it will keep, but I would still try to use it up within 6 months.

Pemmican: Real old-time pemmican was made by the pioneers from lean portions of venison, buffalo, or other meat. It was an Indian trail food that was light to carry and didn’t spoil. It contained all the food elements a person needed except vitamin C, and if berries were in it, it had that too. To make it as they did, cut away the fat from the lean. Sun-dry the lean meat in thin jerky-like strips. Then pound up the jerky until you have shredded jerky. Cut the raw fat into small chunks. (This works best, of course, with a fairly firm fat.) Gradually melt them in a pan in the oven or over very low heat. Don’t ever let this grease boil up.

The proportions should be 1 part lean to 1 part fat by weight. Since it takes about 5 lb. lean beef to make 1 lb. fully dried jerky, you’d start this recipe with proportions comparable to 5 lb. lean to 1 lb. fat meat. When the fat is all melded, pour it over the jerky bits; then mix the two together. It will look quite a bit like regular sausage. No salt at all should be included. Dried berries are optional. Package the pemmican in commercial sausage casings or some other waterproof container such as plastic bags. When you need it, cook it like sausage or eat it in chunks or slices like dried beef.

### Meat Products

Here’s an alphabetical list of some basic meat products you can make at home the old-time way.

#### Gelatin

By “jelly,” the old-time recipe writers meant gelatin. Now we call pectin-jellied preserves “jelly” and animal jellies “gelatin.” To Great-Grandmother they were both “jelly.” “Stock” means soup broth. Homemade gelatin is strained, clarified meat stock flavored any way you like. It sets up (jells) when it is chilled. It melts when it gets warm. To firm it, just chill again and it will set up again.

Gelatin is made from bones and ligaments. Commercial gelatin is made from skins, bones, and sinews. Feet are the boniest, ligamentiest part of the animal and not good for anything else in the kitchen. If you don’t have “4 calf’s feet” for a recipe, substitute 2 lb. or more of soup bones. “Calf’s foot jelly” is a traditional old-time dish, but you can actually make homemade gelatin from cow’s heels (the same as feet, only grown up); beef soup bones; sheep or goat legs; pig’s feet or backbone; chicken necks, heads, backs, feet; or any other bony pieces you’ve got.

I make homemade gelatin as often as I can get the makings. We butcher here at home fairly often, and friends who butcher often let me have the feet. You can’t buy feet to make jelly. Our local custom butcher is compelled by law, in the name of “health,” to put all cow’s feet from the knee down into a barrel and pour creosote over them, so he can’t sell them to me to make gelatin or even give the bones to a neighbor lady’s dog for gnawing. (That law is stupid and wasteful. By the time you’ve boiled the feet 4 to 7 hours to make gelatin, I’m sure no germs can survive.)

After trying my first homemade gelatin, I really noticed the contrast between it and the acid bite and heavy sweetness of the presweetened, prefavored commercial gelatin powder. Homemade gelatin hasn’t been bleached, preserved, or sugared. Its taste is very mild with a hint of meat flavor. I like beef and pork jelly best. My chicken jelly is a bit too chickeny, although adding extra flavoring helps disguise the chicken.

Learning how to make gelatin was a real research job for me. I started out with an antique recipe and had to experiment for a long time to figure out what was meant. Here, for you, is everything I learned about making homemade gelatin.
**Cooking the Making:** After butchering, you can keep feet (skin and all) and other bones for jelly making in big paper bags in your freezer until you have time to work with them. Start your jelly at least the day before you plan to use it. I'll forewarn you — you don't get an awful lot for your work. This is a rare and precious delicacy.

Here's an outline of how to proceed:

1. Prepare bones. (If you're the independent type, that means "butcher.")
2. Cover them with water and simmer until reduced by at least one-half (4 hours or more) to get concentrated stock. (For specific directions for each kind of animal, see the following paragraphs.)
3. Chill enough to set up firmly. Remove fat from top and sediment from bottom of gelatin.
4. Clarify (complete directions given later).
5. Flavor to suit yourself (recipes later).
6. Set, serve, and enjoy!

**Calf's Foot (or Cow's Heel) Gelatin.** Start with 4 calf or cow legs (or 3 or 5, if your cow is odd that way). Cut the foot off each one at the first joint above the hoof. Use a sharp knife and a lot of elbow grease (depends on how good you are at finding joints). If you cook the leg bones, too, you'll have even more gelatin, but you'll need a big kettle or you'll have to saw them in chunks with a meat saw. Put the feet in a pan of hot water and boil 15 minutes. Remove. Stir the skin away from the hoof through the top portion of the hoof, which you'll discover is soft. Cut in two between the "toes" and right on up through so that each foot is now in 2 pieces. Remove as much of the fat from between the toes as is possible. Rinse them. Put into a big pan with a gallon of cold water. Bring it gradually to a boil. Gently boil, uncovered, 6 or 7 hours. Several times, skim off the scum that rises to the top as it cooks. When the water is down to about 1 quart, take the feet out of the pan.

Strain the liquid through a cloth or fine sieve. Measure it. Put it in the refrigerator or in a cool place and let it set up. In the morning take off the fat that has accumulated on the top and quickly rinse the outside of the pan in a little hot water for a moment to loosen the jelly. Then turn it over and the jelly will slip out. Trim off the sediment from the bottom. Clarify.

**Pig Gelatin.** For some reason I think you get more gelatin from pig bones than from any other animal. Use the whole foot from the knee joint down. The backbone is very good for jelly making too. Leave the skin on if the hair has been scraped off. Otherwise, skin the feet. No need to cut or trim. Cover with water and boil gently 4 to 7 hours: skin, toes and all. Skim off scum and fat several times while it cooks. Strain through a sieve to get out the bones and meat (save that for other dishes). Chill overnight. If your broth doesn't jell firm enough to suit you, boil it down some more.

**Mutton or Goat Gelatin.** Boil leg (shank) bones of sheep or goat for 6 or 7 hours.

**Chicken "Foot" Gelatin.** Use the head, feet, necks and backs, if you don't need them for something else. Or if you're a purist, use just the smooth legs of birds less than a year old. With luck, about 3 pairs of feet will make a pint of jelly. Scald with boiling water and cook slowly a long time.

**Clarifying:** The clearer you can get your jelly, the more attractive the final result will be and the better it will combine with other foods in recipes. Clarifying also reduces the animal flavor. But homemade gelatin, even when well clarified, is still a little on the milky order and not crystal-clear like store gelatin. For every quart of gelatin in your pan, add ½ c. sugar (white or brown) or honey, along with the shells and slightly beaten whites of 5 eggs (less if you're short, but it won't turn out quite as clear). Stir in the sweetening, shells, and egg whites as soon as the jelly is melted. You can leave out the sweetening if you want; it will still clarify.

The following recipes are based on sweetened gelatin. Don't stir the jelly after it begins to get really warm. Let it boil 10 minutes, add ½ c. cold water, and let boil 5 minutes longer. Take the pan off the fire, cover tightly, and let stand for ½ hour in a warm place. Strain through several thicknesses of cloth. Dipping the cloth in hot water and wringing it out helps prevent the jelly from setting in the cloth during the straining process. Strain while hot; otherwise it will jell in the bag. You'll probably have to apply some pressure. Wring the loose ends of the bag to force the broth through. If it isn't clear enough the first time, you can put it through the cloths again.

**Setting Up:** The stiffness of your jelly depends on what part of the animal you make it from, how long you boil to concentrate it, and how much liquid you add while preparing it for table consumption. The stiffer you make it to start with, the more possibilities you have for adding flavoring later. Once you have your jelly you can divide it, using 1 part in 1 recipe and 1 part in another. If you're tasting as you go, be reassured: it tastes more like a proper gelatin after it has set up.

For the following jelly recipes, set up the jelly in your final serving molds, preferably individual ones like custard dishes, because it doesn't transfer well once set; it tends to lose shape and shine. Use cold sauces only. It melts easily. Serve chilled; it melts at room temperature. If it starts to melt on you or gets broken up, just finish melting, return it to the refrigerator, and it will again set up very nicely for you.

**Secrets of Good Gelatin Making**

1. If your gelatin does not set up, you used too much liquid for the amount of gelatin. A scant tablespoon of powdered commercial gelatin will jell with 2 c. liquid.
2. Some ingredients prevent gelatin from setting up. Pineapple, papayas, mangoes, and figs have enzymes that react with the protein in the gelatin and cause it to stay soft. Use these fruits or their juices in gelatin only if they are cooked first.
3. To keep solid ingredients from settling to the bottom, wait until the gelatin is partially set before adding them and mix them in gently, distributing evenly. Banana slices, strawberry halves, and chopped nuts and apples tend to rise to the top of gelatin. Fresh grapes, canned fruits, and orange slices tend to sink to the bottom. Use these tendencies to create layered desserts.

**MY FAVORITE GELATIN** Let jelly melt over low heat in pan. Add grape or orange juice frozen concentrate (I can make my own frozen concentrates) and lemon juice to taste. Cool the jelly. Add chopped, peeled apple and let set up again.

**COFFEE JELLY** Melt 1 c. jelly. Combine 2 t. instant coffee with 2 T. water. Add to jelly. Pour into mold and let chill to set. To make this with regular coffee, combine a very firm jelly with enough strong coffee to flavor. Add extra sweetening, if desired.
LEMON JELLY Combine 1 c. jelly and the juice of 1½ lemons. Strain the lemon juice through a cloth before adding it to keep the gelatin as clear as possible. Chill.

OLD-FASHIONED WINE JELLIES Start with a very stiff jelly. Add lemon juice and either red or white wine to taste (I prefer red). To a white wine jelly, you could add some orange juice and grated (unparaffined) orange and lemon peel. To red wine jelly, you could add red berries such as raspberries, strawberries, and currants.

FRUIT JELLY A thick gelatin can take the fruit directly and it will remain in suspension. Let it partly set up, and then add the fruit. In a diluted gelatin, the fruit sinks to the bottom. In that case, chill a bottom layer until firm; then add another layer of fruit and then more melted gelatin. Chill until firm again, add another fruit layer, and so on. Fresh peaches, apricots, plums, and apples are good if cooked in a little sweetened water before they go into the jelly. (Drain thoroughly before adding.) Strawberries, raspberries, grapes, cherries, chopped peeled apples, and currants can go in raw. Your own sun- or oven-dried fruits and brandied cherries are fine too. Cut up large pieces before adding to the jelly.

JELLIES AS SAUCES FOR MEAT: Great-Grandmother served animal jellies with a sauce when she was able (the same way she served the bread varieties she called "pudding"). The easiest sauce is whipped cream. For salad-type jellies (make with raw vegetables, home sun-dried fruit, and fruit juices), serve homemade mayonnaise, sour cream, or yogurt dressing.

VANILLA SAUCE This is nice on a dessert jelly and uses up egg yolks left from clarifying. Scald 1 c. milk. Add a little sweetening, 2 or more egg yolks, and ½ t. cornstarch. Cook, stirring constantly, in your double boiler until it thickens. Add a bit of real vanilla flavoring. Stir until cool.

Substituting Your Gelatin. In modern recipes, use 2 c. homemade gelatin for “1 envelope” commercial gelatin, and cut back on the fluid by 2 cups.

OTHER GELATIN PRODUCTS

Homemade Meat Glaze. This adds color and flavor to soups, sauces, and gravies. To put on meat, melt the glaze over hot water and apply with a pastry brush. To make it, start with your bone stock as for homemade gelatin and boil it until greatly reduced, keeping it well skimmed. Do not clarify. Figure on boiling 1 qt. bone stock down to a cup or less, transferring it to a smaller pan as it reduces. To get a darker color, simmer the concentrated stock with caramelized sugar until it becomes like a syrup.

Bouillon “Cubes.” Make your stock and concentrate, but do not clarify. Whatever type of meat you used will be the flavor of the cubes you get. Remove fat but not sediment. When you have a well-jellied stock, you’re ready to make bouillon cubes.
1. Melt the jelly.
2. Season it strongly with your favorite soup seasonings.
3. Pour the seasoned jelly 1 inch deep into some containers you can get along without, like cans—the smaller the better.
4. Set the cans in a water bath that reaches about one-third up the side of the can. Cook on low heat at least 8 hours more, refilling the water bath as needed.
5. Chill.

Gravy

Good gravy to go on the potatoes can be made any time you fry or roast meat. When your meat is done, remove it from the pan. Estimate how much gravy your family can use. If you want 1 cup, pour off the grease until you have about 2 T. left, 4 T. for 2 cups, and so on. If you don’t have that much, add a little melted butter, bacon drippings, or lard. Loosen all the good brown bits in the bottom of your pan (assuming you don’t have a burnt mess, in which case salvage some grease by pouring off the top and start over in another pan), and add 2 T. whole wheat or unbleached flour per 2 T. grease.

For heaven’s sake, don’t stop to actually “measure” the hot grease and flour. You can learn to estimate close enough by looking at it, and it really doesn’t make that much difference if you use a little more or less of either. Just don’t have a whole lot of extra grease, because it will float on top of your gravy and look and taste yuh!

Over medium heat make a paste of the brown bits, grease and flour with your fork, and let cook a couple minutes, stirring constantly. This accomplishes the browning and cooking of your flour and gives you almost an “instant” gravy. Your mashing action with the fork will break up potential lumps. Now pour in a little liquid. Stir it in until the lumps are gone; then add more and stir again until the lumps are out. Repeat until all your liquid is added. You can add more liquid each time, but start with very little. Stop adding liquid when your gravy is as thin as you want it.

For liquid, use your potato water, water from another cooked vegetable, or milk. Or juice from a pot roast or stewed chicken, if you have it. I drain the vegetable waters into the gravy (or else add them to the animal pail) and then cook that down to the wanted density. Pork-chop gravy is good with half milk and half water or all milk. Chicken gravy is good with half or all milk. Beef gravy is good with part milk or just your vegetable water. Deer, elk, and other game gravies don’t get along with milk. Game gravies are much improved by adding a couple tablespoons of currant, wild plum, or some other tart jelly. For roast turkey, duck, or goose, use no milk, but add the chopped cooked giblets and the giblet broth for a delicious gravy.

If you get the gravy too thin and watery, you can boil it until it thickens enough to suit you. Finally, salt and pepper to taste. Taste it until it seems right, but don’t burn your tongue! Good gravy seasonings are black pepper, onion powder, thyme, sage, marjoram, and basil. For a final garnish, sprinkle freshly chopped parsley, dill, chives, or scallions on top. Then serve to pour on your meat and mashed potatoes, rice, or thick slices of bread in a sturdy bowl with a good dipper. And put the pan to soak in the sink, so it won’t be a chore to wash.

Gravy Trick. Put flour in a jar with a tight-fitting lid. Add cold water, about 1½ times by volume. Shake by hand. Never fill jar over three-fourths full. Add to the gravy or stew slowly, stirring the whole time. From Howard Perkins, Pennsauken, NJ.

Roux. From Virginia Boegli, my high school friend who drew some of the illustrations for the early editions of this book. "I've discovered a great little French technique that..."
really simplifies gravy. It’s called roux (pronounced “roo”). A roux is a paste of about equal parts fat and flour. The fat may be drippings or butter or so forth. A roux can be blended into hot liquid without all that lumpiness. When my roasting pan has a hard brown coating after roasting meat, I like to put water in it and simmer to get all that good stuff. Then stir in a roux and seasoning—voila, it’s gravy. If you want you can make a jar of roux and keep it in the refrigerator. A glob the size of a walnut thickeners about a quart of gravy or a large pot of stew. If in doubt, it’s easy to add a little at a time.

White Sauce. This is a meatless white gravy. It’s good poured over bland vegetables such as boiled onions, cauliflower, or asparagus. I mix white sauce with diced leftover ham (omit the salt for home-cured ham) to get an extra gravy. If you cook an especially moist hash slowly in a covered pan for about half an hour, until there is a rich crust on the bottom, you can fold it in an omelet and serve that way. Hash is a good breakfast (or lunch) dish with eggs on the side, and it’s good for using up leftovers.

When you want to eat it, turn it into an oiled frying pan and bake in a hot oven until brown, or fry on top of the stove, turning once. Slightly beaten eggs mixed with the hash will make it stick together better if you don’t use gravy. If you cook an especially moist hash slowly in a covered pan for about half an hour, until there is a rich crust on the bottom, you can fold it in an omelet and serve that way.

Hash

The basic hash recipe is to grind or cut into small pieces cooked meat (mutton, beef, corned beef, or what-have-you) and add diced cold boiled spuds. The usual proportion is half meat and half potato. Some people stretch it with more potato. You can add chopped onion too. Moisten with left-over gravy, soup stock, egg, or even milk or water. Season with salt and pepper. I usually make it with leftover gravy.

Hash

The basic hash recipe is to grind or cut into small pieces cooked meat (mutton, beef, corned beef, or what-have-you) and add diced cold boiled spuds. The usual proportion is half meat and half potato. Some people stretch it with more potato. You can add chopped onion too. Moisten with left-over gravy, soup stock, egg, or even milk or water. Season with salt and pepper. I usually make it with leftover gravy.

When you want to eat it, turn it into an oiled frying pan and bake in a hot oven until brown, or fry on top of the stove, turning once. Slightly beaten eggs mixed with the hash will make it stick together better if you don’t use gravy. If you cook an especially moist hash slowly in a covered pan for about half an hour, until there is a rich crust on the bottom, you can fold it in an omelet and serve that way.

mincemeat on each dough round. Fold the dough over, pressing edges together with the floured tines of a fork or with a fingertip (a square thus would become a triangle). Put the filled cookies on a greased cookie sheet. Bake at 400°F 8 to 10 minutes.

**MINCEMEAT COOKIES** Cream 1 c. shortening. Add ½ c. brown sugar and blend well. Add 2 eggs and beat thoroughly. Mix ½ t. salt and 1 t. soda with 3 ½ c. flour. Alternately add ½ c. mincemeat and the flour mixture to the liquid mixture. The liquid amount determines how liquid your mincemeat will be. You might want to add a little more or less flour to get the right cookie consistency. Finally, add ½ c. chopped nuts (more or less depending on how many you have). Mix. Drop with a spoon onto your greased cookie sheet. Bake 10 minutes at 375°F.

**MINCEMEAT JELLY ROLL** Combine 2 c. sifted flour, ½ c. sugar, 1 t. salt, and ½ c. milk. Add 1 T. dry yeast dissolved in ½ c. lukewarm water and a beaten egg. Let rise. Punch down. Let rise again. Divide dough in half. Roll out each half to a ½-inch thickness. Spread a layer of your mincemeat over each half. Roll it up jelly-roll style. Pinch edges to seal. Let rise once more. Bake at 350°F about 30 minutes, or until nicely browned and crusty on outside.

**MINCEMEAT MUFFINS** Beat 1 egg with 1 ¼ c. milk. Add 2 t. melted butter. Combine 3 c. whole wheat flour, 3 t. baking powder, 1 t. soda, 1 T. sugar, and 1 t. salt and then add to liquid. Add 1 c. mincemeat and 2 t. fruit juice or water. Mix it all together well. Grease your muffin tin and fill the cavities two-thirds full. Bake at 375°F for 25 minutes.

**CRANBERRY MINCEMEAT PIE** Combine 1¼ c. mincemeat-chopped apple combination, ½ c. cranberry sauce, ½ c. orange juice, and 3 T. flour. Pour into an unbaked shell. Cover with a top crust. Pinch sides and brush the top with milk. Bake at 400°F 50 minutes.

**MINCEMEAT-OATMEAL COOKIES** Sift together ½ c. plus 2 T. flour, ½ t. soda, and ½ t. salt. Cream ½ c. lard and then gradually add 1 c. brown sugar. Add 1 well-beaten egg and 1¼ c. mincemeat. Add flour mixture gradually and then 1½ c. rolled oats. Drop by spoonfuls onto greased cookie sheet. Bake at 350°F about 15 minutes.

**MINCEMEAT APPLES** Try baking apples with the cores out and the cavity stuffed with mincemeat.

**MINCEMEAT BROWN BETTY** Make 2 c. bread crumbs, preferably from homemade whole wheat bread. Butter a bread pan. Put one-third of the crumbs in it. Add a layer of 2 peeled, sliced apples and then a layer of ½ c. mincemeat. Sprinkle over a pinch of cinnamon. Add another layer of crumbs, 2 more sliced apples, another ½ c. mincemeat, another sprinkle of cinnamon, and the remaining crumbs. Pour ½ c. orange juice over all. Dot with butter. Bake at 350°F for 30 minutes. Good with cream.

### Sandwich Mixes

These sandwich fillings are meant to be spread on homemade bread. Store-bought bread is too salty and generally "strong"-tasting for them. Any leftover meat can be made into a fine sandwich filling. Just remove bone and fat (except for old-time potted ham). Slice or grind the meat. Moisten the grindings with a salad dressing, such as mayonnaise or cream dressing. You can make plain meat fillings this way or with the variations that follow. Croquettes are another good way to use meat leftovers. So is sliced meat warmed up in leftover gravy and served with rice or sliced boiled spuds that have been sauteed in a little butter with some chopped fresh green onion.

**HAM AND EGG** Grind the ham with chopped hard-cooked egg. Moisten with mayonnaise or cream dressing. Add finely chopped red or green pepper and mustard.

**HAM AND PICKLE** Grind 2 c. ham. Mix smooth with 1 small ground pickle, 2 t. prepared mustard, 2 T. butter, and ½ t. pepper.

**HAM AND EVERYTHING** Mix together 1 c. chopped ham, 1 chopped hard-cooked egg, 2 T. chopped green pepper, 2 T. chopped sour pickle, and a pinch of pepper. Moisten with mayonnaise. Add thin pickle slices and strips of green pepper, if desired.

**OLD-TIME POTTED HAM** Grind one-third fat and two-thirds lean meat to a smooth paste. Add salt and cayenne pepper to taste. Heat and pack in small pots.

**HAM AND CHICKEN** Grind 1 c. cooked chicken meat, white or dark, and ¼ c. cooked ham. Mince ¼ c. celery and 1 T. green pepper, and mix with meat. Moisten with about ½ c. mayonnaise.

**CHICKEN SALAD SANDWICH FILLING** Grind cooked chicken and moisten with mayonnaise. Add crumbled crisp bacon or chopped celery.

**CHOPPED VEAL** Grind about ½ c. veal and season with 1 t. salt, 1 T. lemon juice, and a little pepper and mustard, if desired.

**CHOPPED MUTTON** Grind until fine about 1½ c. cold mutton or lamb. Season with 1 t. salt, 1 T. pickled nasturtium seeds if you have them, 1 t. chopped fresh mint if you have it, a pinch of pepper, and 1 T. lemon juice. Good on whole wheat bread with lettuce.

**BEEF SANDWICH SPREAD** Grind the meat, add mayonnaise, salt, and pepper to taste, and stir in some chopped green onion or green pepper or pickle. Doesn’t keep well, so eat it all up.

### Homemade Lunch Meat Loaf Recipes:

From Gertrude Johnson, Lamont, WA, a rare and splendid lady who says these homemade lunch loaves have no chemicals or nitrates and are inexpensive to make and very tasty.

**TURKEY SANDWICH ROLL** This recipe makes lunch sandwiches for a week for a family of 3. Place 2 turkey drumsticks (or 2–2½ lb. meat), 3 carrots (scrubbed and cut into
chucks), 3 ribs celery (including the leaves, scrubbed and cut into chunks), 2 medium onions (peeled and cut into chunks), 4 whole peppercorns, and salt to taste together in a large, heavy pot. Fill with enough water to cover the contents plus 1 inch more. Bring to a boil; cover and simmer about 2 hours or until the turkey is no longer attached to the bone. Remove meat and set aside until cool enough to handle.

Strain turkey broth into a bowl through a cheesecloth-lined strainer. Set the bowl aside. Discard the cheesecloth and its contents. Remove and discard the skin from the drumsticks; then remove the meat from the bones. Use your fingers to shred the meat and to check for any stray bones. Put the shredded meat into a clean saucepan. Add just enough turkey broth to pan to moisten the meat without making it soupy. Set the pan on low heat and stir to further shred the meat as much as possible. Add salt to taste. Very gradually, add enough broth to keep the meat generously moist but not soupy.

When this is heated through and seasoned to your liking (try including 2 T. dried parsley flakes or ½ c. fresh parsley and 3 thin slices of lemon), remove from heat and sprinkle 2 envelopes of unflavored gelatin on top. Stir constantly for 3 minutes. Pour mixture into a deep quart-sized, lidded container or into an 8 x 4 x 2-inch loaf pan. (Greasings are not necessary.) Cover and refrigerate overnight. When set, remove the roll from its container and cut it into slices for sandwiches. It will keep (refrigerated) for about 2 weeks. Do not freeze!

BARBECUED BEEF SANDWICH LOAF You'll need 1½ lb. stewing beef, 1 large onion, peeled and quartered, ½ t. salt, ⅛ t. pepper, ½ c. barbecue sauce, 2 c. water, and 2 envelopes plain gelatin. Cut beef into ½-inch cubes. Place meat in heavy pot with onion, salt and pepper. In a separate bowl, combine barbecue sauce with water. Pour two-thirds of this mixture over meat cubes. (Set the rest aside.) Bring meat mix to boil and simmer, covered, over low heat for 1 hour or until beef is very tender. Then shred beef and onion in blender, using all of the pan juices and the rest of the barbecue and water mixture. Finish as above with the gelatin, etc.

HAM AND CHEESE LOAF Make this when you have leftover ham (or other meat) that is in shreds and bits, unsuitable for serving. You'll need 1½ c. leftover cooked meat, water, 1 envelope (1 T.) plain gelatin, and ½ c. diced cheddar cheese. Shred, mash, and then chop ham into very small pieces in a small saucepan. Gradually stir in enough water to moisten, plus 3 T. more. Bring to a boil, remove from heat, and sprinkle gelatin on top, stirring for 3 more minutes. Let mixture reach room temperature. Then stir in cheese and pour into a lidded 2-cup plastic container. Cover and refrigerate overnight. When set, remove from container to slice for sandwiches. Do not freeze.

Sausage and Hamburger
NOTE: In the following recipes, there are no chemical preservatives, so as a safety measure, follow these instructions:
1. Use only fresh rather than aged meats.
2. After making your sausage, immediately store in a freezer that is set at 0°F or below.
3. Or preserve by canning. (Follow the directions in the "Canning" section for ground or chopped meat.)
4. Cook frozen sausages thoroughly before eating.

SUPPLIES AND BOOKS: To shop for casings, ask the custom butcher in your area. Larger cities may have stores that specialize in sausage, or your local market might order them for you from their wholesaler. If that doesn't work, check the Yellow Pages under "Meats, Custom Cutting" and "Meats, Wholesale." The Sausage Maker sells everything you need for making sausage and curing meats, including spices, tools, casings, equipment, and an instructional video/book combo deal for $39.95. That book, Great Sausage Recipes and Meat Curing, by Rytek Kutus, contains 175+ sausage recipes: 880-490-8525; 716-824-6510; 1500 Clinton St., Bldg. 123, Buffalo, NY 14205; sausmaker@aol.com; www.sausagemaker.com. Luhr Jensen offers a "Home Sausage Kit" with a booklet of instructions and recipes, as well as sausage-making supplies: 800-533-1711; 541-386-3811; PO Box 297 (400 Portway Ave.), Hood River, OR 97031. Order Home Sausage Making: Healthy Low-Salt, Low-Fat Recipes (including poultry and fish recipes), by Charles Reavis, from Storey Books, address in Chapter 1. You can buy sausage mix that does not contain MSG from the KOCH company: 800-456-5624. Meat grinders and sausage makers are also available from 719-962-3228; www.familyresources.com.

GRINDING AND MIXING THE MEAT: Sausage making is an important country art in this part of Idaho, maybe everywhere in the country. The arrival of late fall and butchering time on the farm means sausage time. Often it is made twice a year: in late fall and again in early spring, when some more butchering is done. In most of the small towns around here, it is a public operation as well as a private one. The communities have an annual sausage-making bee followed by a big sausage feed.

Hamburger Making. "Hamburger" is ground meat with whatever percentage of fat added or left out that you prefer. The precise point at which ground meat stops being "hamburger" and becomes "sausage" is vague. If pork is added, the result is generally called "sausage." Hamburger and sausage are basic meat foods, a way to make use of all your meat scraps. When you butcher wild animals and small animals like goat, you get so many odds and ends of meat pieces (especially if you are boning out the meat), that ground-meat recipes are the answer. Grinding also solves the problem of using tough, old animals. And ground meat is easy to heavily and thoroughly season, so it also can solve the problem of what to do with strong-tasting meats. Hamburger and sausage can be heavily or lightly seasoned—
Better than trying to grind sausage in a little home grinder is to take a dishpan or two of it to your local butcher. But check first to see if the butcher feels able to do it for you. There are so many new laws now that discriminate against home-butchered meats that he or she may not want to take the chance.

It helps to use a larger model of meat grinder (Food Grinder Pro, $100, or Stainless Steel Meat Grinder, $150, from Back to Basics, 801-571-7349). Or mail-order a sausage grinder and stuffer from Lehman's (888-438-5346; www.lehman.com); they sell other sausage-making equipment, too. A typical bargain grinder has the 2 disks for fine or coarse grinding and a 7/8-inch stuffer attachment. It's crank-operated. Power grinders are the nicest of all, if you have the kind of handyman who can hook up a washing-machine motor to anything.

Before you grind the meat, trim it from the bones and cut away all gristle and blood clots. Cut it into strips, whether it is fat or lean. Put your fat in one pile and your lean in another to help you have a notion of proportions. You're supposed to use one-third fat and two-thirds lean, and you can kind of judge that with your eye. I don't see much use in the fat part, however, so I generally just use whatever fat comes along of its own accord, and the fat that I can easily cut out goes into the rendering pail.

**Seasoning.** Some people grind their meat coarse and then add the seasoning and grind again. But it's too much struggle to grind more than once, and it's easier to mix the seasoning with the meat before grinding than after. So do it like this. Cut the meat in strips. Lay it out on a mixing surface, such as a sheet of freezer paper with the wax side up. Sprinkle the seasoning on and mix with your hands. Sprinkle again and mix again until you have it well mixed. You can season about 20 lb. at a time this way. It's much easier than working with it ground.

Now grind. If you have a very good grinder, you can form your ground sausage into fist-sized balls and put them through the grinder again. It really helps to have a wooden "follower," which is a basic cylindrical meat pusher, so you don't grind your fingers but do hold the sausage in the grinder.

If you aren't sure of your seasoning amounts, make a little sausage cake up on the spot, fry it, and eat it. Then you can adjust the seasoning of the rest accordingly. Don't taste raw pork because it's been known to carry trichiniae, a parasite that causes a horrific disease. A woman at my college got it after eating several hot dogs in Chicago. She got really sick and had to quit school. I can't imagine our home-grown pork having any such thing because pigs get it from eating infected meat, and I know where everything that our pigs eat comes from. Nevertheless, it's a good idea not to taste raw pork.

If you decide to add more seasoning to your already ground meat, mix it in a big kettle. Get ready by washing both hands clear up to your elbows, and then plunge in. Knead as for bread dough, picking up from the bottom, pulling up over the side to the top, and punching into the center. In a moment give the kettle a quarter turn and continue. Some people grind the meat coarse, add the seasoning, and then grind it fine. That's okay if you have a good power grinder.

The seasoning can be as simple as salt and pepper. Or it can be a very, very complex mixture. Morton Brothers (the salt people) makes a sausage seasoning that's sold in our local grocery stores. Some people add a little Tenderquick to their seasoning; some make it all from scratch. The commercial seasonings contain a lot of spices blended with salt as well as monosodium glutamate and preservatives. Use 8 oz. seasoning per 24 lb. meat for strongly seasoned sausage. For a milder sausage, use 8 oz. for 35 lb. meat. I've tried just grinding and freezing the sausage plain and then seasoning it right before I cook it, but it doesn't have the best flavor that way. The seasoning needs a chance to work in.

**ABOUT CASINGS:** You travel one of 2 basic routes, the easy one or the hard one, in shaping the ground seasoned meat into sausage. The easy way is to make patties. Sausage
that is seasoned and frozen in breakfast-sized packages, which you can simply thaw, shape into patties, and fry (or sausage-fry and then can), is just as much sausage as the kind that's stuffed into casings, and it's a lot easier to make. The harder option is to stuff the mixture into casings. Stuffing casings is extra work and expense (or time if you clean your own casings). At home I usually just wrap my sausage bees, while the men butcher the hogs, the women clean the small intestines, and those become the sausage casings. They make sausage and stuff the casings and then smoke them in a little smokehouse right there.

You can use plastic, muslin, or gut casings. Casings are sold by the "hank," which is a 1½-lb. package that is supposed to stuff about 100 lb. of sausage. You don't eat the plastic casings, of course, or the muslin ones. But when you make sausage with casing made from the natural gut, you eat the casing too. Plastic casings used to be readily available but are hard to get now. They were sold in 1-inch, 2-inch, and 4-inch sizes. Two-inch was generally the most satisfactory.

**Homemade Muslin Casing**

![Image of homemade muslin casing]

**Making Muslin Casings.** Don't dry sausage in these. You have to strip the muslin off first. Sew 8 × 18-inch strips of muslin. This allows for a ⅛-inch seam. Fold and sew up 1 end and turn inside out. Firmly pack the sausage in there. Be sure there are no air pockets, because air pockets may cause mold to grow on the inside of the casings. Tie the top with a heavy cord and give it a loop to hang up the sausage. Be sure to dip your muslin casings in water and wring them out before starting to stuff them. If you don't have a sausage stuffer, you can spoon sausage into big casings like these.

**Making Natural Casings:** There are 3 kinds of natural casings, and a really good sausage stuffer has 3 nozzle sizes. Little-pig size (what they call link sausage) is about 2 inches long and ½ inch wide and is a sheep casing. Beef casings are used to hold salami-type sausages. Pork casings make traditional "sausage" sausages. A hank of pork casings is supposed to stuff 100 lb. of pig—but about 85 lb. is more likely. Sheep casing will take 50 lb. Beef casing will take a lot. You can buy natural casings in quantity and keep them in your freezer. I have a friend who kept hers there for 4 years before they were all used up, and they kept fine. Soak them in warm water before stuffing.

Making natural casings is cold, tedious, hard work, and it's not for the squeamish. You need a fairly low faucet or hose that runs water on the ground, a knife to cut the gut when it shows a hole or tears, and a set of knitting needles. If you are going to clean casings, it's doubly important that the animal not be fed for 24 hours before butchering. The casing is made from the small intestine of the animal (sheep, cow, or pig). If there is food in there, it makes a lot of extra work to get it out.

If you are planning to save casings, it's a good idea to keep your pigs especially well wormed. (Worm medicine is a liquid that you mix with a gallon of water and have them drink.) Not only is it disagreeable being in the same vicinity as a bunch of 6-inch-long, husky, writhing, white roundworms, but they also make holes in the intestine. A really infested pig will have a gut like a sieve.

1. Cut the small intestine off where it starts below the stomach, and cut it on the other end where it is about to connect up with the large intestine. You'll have to rescue it from the general pile of innards. Put it in a big dishpan.

2. Carry it over to your faucet or hose. Strip it between your fingers or between knitting needles to remove as much of the contents as possible—food, worms, or what have you. Just let them spill out on the ground. Then rinse them off under running water. This is where the agony starts, because sausage and butchering weather is cold weather, but you have to do all this work with your bare hands because the gut is delicate and is the job. Your cold, wet hands will be in a state of near-paralysis after the first 10 minutes. It's not so bad if you're doing just 1 gut, but if you're doing more than one, it's nice to have somebody working with you so you can take turns freezing your hands working with the casings or thawing them out over the nearest fire.

3. You have the gut contents stripped out as best you can and the outside rinsed off under your faucet. Now you're going to turn the entire gut inside out. There's a neat trick to this turning. Practice beforehand in the house with something like a sock, when your hands are warm and dry, till you feel you'll be able to do it even with wet, frozen hands and a slippery gut:
   a. Take a sock.
   b. Hold it upside down.
   c. Start turning it inside out.
   d. Keep in mind that if it was a gut rather than a sock, it would be about 2½ feet long and slippery. The way to get it turned inside out is by water pressure. The hard part is getting it started. Returning to the sock, if you turn socks inside out like I do, you have your thumbs in a sort of pocket you've made all the way around. Now you're going to run your water into that pocket. Since the gut is waterproof, the water pressure going into the pocket will push on it and draw more and more of the gut inside out until you're clear to the end. If you run into a wormhole or the gut starts to tear, you lose your water pressure as the water starts to leak out the hole. In that case, cut the gut at the point of the leakage and start over again with the part that hasn't been turned yet.

4. Put your turned, cleaned casings in a pan. Now get 2 knitting needles. Put 1 end of the cleaned gut between the knitting needles. Have somebody hold the needles tightly together while another pulls the casing through between them.
5. Rinse them some more.
6. Store in cold water if you’re going to use them soon. Otherwise freeze them. Soak in warm water before using.

CHITTERINGS This is a Southern name for casings used as a meat dish. Having gotten them this far, you soak them in vinegar to remove the smell and then cook.

STUFFING THE CASINGS: The stuffer is basically a nozzle with a container on top, fixed so you can put pressure on the contents. The pressure forces the sausage out through the nozzle and into the casing. The simplest sort is just a funnel. You hold the casing under the funnel and push it through with your hand. The usual sausage grinder has a stuffer attachment. Using the attachment, you turn the crank to force the sausage out of the nozzle into the casing until it is full. Pack the casing as tightly as possible. At the sausage-making bees they have a special big crank-operated sausage stuffer, but that's not practical for one individual or family.

If you’re going to have only one stuffer size, it’s better to have it too small than too large. Really nice stuffers have 3 nozzles for the basic casing sizes, but ordinary ones have just one size, 1/4 inch in diameter. It has to be small enough that the smallest casing can easily slip over the end of the nozzle.

Step-by-Step Guide to Stuffing Casings
1. Separate out a length of casing.
2. Put the entire casing over the nozzle of the stuffer.
3. Pinch the free end shut with your left hand.
4. Have a helper run the stuffer. The casing will unfold itself as the sausage is forced into it. To make a round sausage, fill about an 18-inch to 2-foot length. To stop the stuffer, crank it quickly backward a half turn of the crank.
5. Pull off a little empty length of casing. Cut the casing.
6. Put the 2 loose ends of the sausage casing together, forming a ring. Tie the ends together with twine or a stout soft white string. If you plan to hang the sausage to smoke it, tie another knot between the 2 free ends of your twine so you have a little ring of string for hanging it up. Your sausage should be long enough to make a comfortable circle and touch end to end. Round

SAUSAGE RECIPES
NOTE: Sausage made from these recipes should be preserved by freezing or canning.

HEALTHY HOMEMADE SAUSAGE For the healthiest sausage, omit salt and reduce fat. Using a mortar and pestle or your blender, make a powder from your spices and add that spice mixture to the ground meat.

CLASSIC SAUSAGE Simply grind your meat scraps and add one-fourth to one-third pork fat and seasonings (salt, pepper, sage, optional red pepper) or one-third pre-seasoned pork sausage. Classic all-pork sausage is made of pork trimmings—one-third fat to two-thirds lean.

CARLA’S DIGESTIBLE SAUSAGE I’m always in a rush, so we just grind the sausage, season it, bag up in the usual meal-sized lot, and put it in the freezer. Just grind up the pork trimmings, using only one-fourth fat. Add hefty amounts of salt, garlic salt, onion salt, dried parsley, sage, and thyme. Leave out the pepper, red pepper, cinnamon, allspice, and so on. This tastes absolutely sausagey and has no bad aftereffects for even the most sensitive eater. I never seem to be able to keep sausage on hand. It gets used up faster than any other part of the pig.

PLAIN PORK SAUSAGE Take 10 lb. fresh pork, 5 T. salt, five.
2 T. sage, and 2 T. black pepper. Grind together. Mix thoroughly some more afterwards to make sure the spices are evenly distributed.

OLD-TIME GARLIC SAUSAGE Combine 20 lb. beef, 40 lb. pork, 1 ground onion, 4 T. garlic juice, 2 c. salt, ½ c. brown sugar, and ½ c. pepper. Mix thoroughly. Set out overnight so part of the liquid can evaporate. Stuff in casings. Smoke with apple wood 12 hours or until casings are somewhat dry.

BREAKFAST HERBIE LEAN SAUSAGE For every pound of lean ground meat add ⅛ t. pepper, ⅛ t. marjoram, ⅛ t. thyme, ¼ t. sage, and ¼ t. savory or ½ t. coriander seed. Mix all together thoroughly. Let rest in refrigerator overnight to help seasonings get well absorbed. Shape into patties, fry, and enjoy.

SPICY SAUSAGE Sample recipe: combine 4 lb. pork (one-third fat, two-thirds lean), 5 t. salt, 4 t. sage, 2 t. pepper, ½ t. red pepper, ⅛ t. cloves or ⅛ t. nutmeg, and 1 t. sugar. Full-scale recipe: combine 100 lb. pork, ⅝ lb. salt, 3 oz. sage, 3 oz. pepper, ⅝ oz. red pepper, and ⅛ oz. cloves or ⅛ oz. nutmeg.

MARJORAM-MACE BULK SAUSAGE Take 85 lb. lean pork, 15 lb. beef, 1½ lb. salt, 4 oz. pepper, 1 oz. red pepper, 1 oz. marjoram, and 1 oz. mace. Cut all meat into small pieces, sprinkle seasoning over, and grind with small plate. Store for 24 hours. Add enough water so you can knead the mixture well. Make into patties; stuff casings and freeze; or smoke and then freeze.

SEASONED SAUSAGE First mix your seasonings; then mix seasonings into meat. For each 2½ lb. ground meat, combine 2½ t. sage, ⅛ t. thyme, ⅛ t. cayenne, ¼ t. pepper, ½ t. garlic powder, ½ bay leaf, crushed, and a dash of celery seed. Mix in seasonings. Grind. It will keep in refrigerator about 2 weeks. To cook, cut into patties and fry slowly or bake at 350°F for 45 minutes. Good with tomato sauce and spaghetti. Crumble as it fries to put on pizza.

BOLOGNA This traditional sausage is made of a mixture of ground beef and ground pork. You could make it if you were butchering both a beef and a pig. That's a pretty natural thing to do come winter cold enough for slaughtering. By then we're low on all kinds of meat. You can substitute mutton or lamb for beef in this type of recipe. The proportion of pork lean and fat to beef can vary, according to taste and convenience, from as little as 5 lb. pork to 20 lb. beef to as much as 15 lb. pork to 20 lb. beef. So to a certain extent, it can just be a matter of how many pounds of beef and pork scraps you have. You might want to save a lot of your beef hamburger, though, to be plain old hamburger, and the same with pork. The nicest mixture is probably 2 lb. lean beef to 2 lb. lean pork with some fat pork (not more than 1 lb.) thrown in.

Season with sausage seasonings and grind. Use 1 t. seasoning per 1 lb. meat. If you want to put together your own seasoning, try salt, pepper, garlic, onion, coriander, and mace. Water is added in the proportion of 3 or 4 pt. per 25 lb. meat. Bologna is traditionally stuffed into beef casings, smoked, and then cooked. Remember to soak the casings before stuffing them. Smoke the bologna for 2 to 3 hours.

Then simmer the bologna just below the boiling point until it floats—15 to 30 minutes. Chill in cold water and hang to drip in a cool place. Then you can freeze it.

LIVER SAUSAGE Along with seasoned pork sausage and blood sausage, this is one of the most popular country sausage recipes around here. Boil 5 lb. pork liver for 1 hour. Strain and discard broth. Cover 5 lb. lean pork and 5 lb. pork skin with water. Add 3 bay leaves, 6 whole cloves, and 1 onion. Boil for 2 hours. Skim the fat from the broth. Remove the meat and cool the broth. Grind the liver and the meat. Add salt, pepper, and garlic salt to taste. Add enough of the broth to moisten the mixture well. Stuff into casings and boil 1 hour. Then keep in refrigerator or freezer. This recipe makes enough to stuff only about 6 casings. Don't smoke liver sausage.

The above recipe is pretty heavy on the liver side. Most liver sausage contains only 10–20 percent liver. You can add your pork head, tongue, and the like to it. In that case, go ahead and cook all the meat except the liver just the way you would for scrapple—until it can be easily separated from the bones. Then cut the livers deeply with a knife and add them for the last 10 minutes. Don't overcook the variety meats. It all gets cooked again in the casings anyway. For 100 lb. meat use 2 lb. salt, 2 oz. pepper, 1 oz. sage, ⅝ oz. red pepper, and 1 oz. allspice. Mix in the seasonings and grind the meat until it's ready to stuff into the soaked casings. Stuff, tie, and simmer in water until it floats (10–30 minutes). Cool, chill, and hang up to drain. Freeze.

SALAMI This is made from meat that might be tough and need grinding or that tastes like a wild meat you aren't used to. The spiciness covers the taste. Don't use any fat from wild meat, except bear, since the wild flavor is generally concentrated in the fat. Wild sausage that's part pork or pork sausage makes a fine breakfast sausage. Wild meat is generally extremely lean, so you can combine it with really fatty pieces of pork and it will benefit. You can use one-fourth to one-third pork. Season and grind up. Then I just bag it up, tie with the wires, and freeze. Each bag holds enough for a breakfast. When we have plenty of wild meat and pork, I make salami by the kettleful. Season with commercial seasoning, 1 t. per pound, or use your own formula. You can add black whole peppers after your grinding to make it authentic. Sage, allspice, garlic, ground cardamom seed, and onion salt are all good in it. After the meat is seasoned, you can stuff it into casings if you like. Smoke about 48 hours (smoking is no substitute for cooking, however). Freeze it and cook it when you are ready for a sausage meal.

POTATO SAUSAGE This recipe was sent to me by the Johnsons of Wheaton, IL. Use 4 lb. ground beef and 2 lb. ground pork. Peel and grate potatoes until you get about 1 qt. grated potato. Use some of the liquid that drains off the grated potatoes so that the mixture is like a soft meat loaf. Grind 3 large onions and add. Add salt, pepper, and ground allspice to taste—⅛ to ⅛ t. The flavor should be subtle. Put this mixture in sausage casings. Don't pack too tightly. Tie the ends. Simmer in salted boiling water for ½ to 1 hour. Freeze. To cook, put in a shallow pan in the oven and brown at 375°F for about 10 minutes.

BLOOD SAUSAGE This recipe makes about 30 lb. sausage. Take 7 lb. fresh pork (cook the day before and save broth), 1 bundle casings (well washed and soaked in water), 3 lb. rice (cooked almost done), 2 lb. barley (also precooked the day of use), ⅛ c. cinnamon, 1 t. cloves, ⅛ t. allspice,
It is probably better to use beef or lamb casings, and the sausage will taste better if you use beef blood. The meat used should be mostly pork; a little beef can be added. Fresh pork hocks, shanks, shoulder, or meat from the hog’s head works great. Fat must be left with it, since it is a necessary ingredient. All ingredients should be ready ahead of time.

Blood should be caught in a manner that keeps it clean. Add a little salt to keep it from setting or stir it. The best way to get a cow or pig’s blood is to shoot the animal and then quickly hoist it. Cut the jugular vein in the neck—or, if you’re a real expert, go straight to the aorta coming out of the heart. Press the neck of a jar to the animal’s neck to catch the blood as it pours out. To get blood from an unhalted beef or pig, just hold the pan so as to catch blood after cutting it open. One hog will give about 1 1/2 to 2 gal. blood. Don’t get blood from nose or mouth. Keep pan under animal, and keep stirring for at least 5 minutes; otherwise the blood will congeal into a lump, and you want to keep it liquid. If you have snow, pack the jar with snow to cool it.

Grind meat and fat. Warm broth. Mix meat, broth, warm rice, barley, and blood. If blood has set, grind it and then mix in add spices. Mix thoroughly. Mixture must be quite warm to put in casings. Don’t pack casings too full. Have a kettle of water boiling. Tie casings, leaving room for expansion. Drop a few at a time into the water. Cook about 10 minutes. Test by pricking it with a needle. If juice is clear, take out and cool. Wrap for freezer.

My family enjoys this fried crisp or put on a cookie sheet or shallow pan in a hot oven until crisp. We use it for either breakfast or dinner. It is very expensive to buy, and what we do buy never seems very good.

**GERMAN FRANKS** Take 5 lb. veal without bones, 5 lb. pork (no fat), 6 lb. lard, 1 3/4 lb. salt, 3 grams (1/8 oz.) pepper per pound of meat, 1 1/2 grams (1/16 oz.) nutmeg per pound of meat. Grind meat very fine together with salt, pepper, and seasoning. Mix well after the grinding. Put into clean intestines and make 6-inch pieces. Prick with fork. Franks will keep a while in refrigerator.

**KIELBASA (POLISH SAUSAGE)** Combine 1/3 lb. pork loin or Boston butt, 1/2 lb. veal, salt and pepper, 1 clove garlic (crushed), and 1 t. crushed marjoram, if wanted. Run meat through coarse grinder. Add 3 or 4 t. water, garlic, salt and pepper to taste, and marjoram. Mix thoroughly and stuff casing. It is now ready to smoke. Or just place in baking dish and cover with water. Bake at 325 to 350°F until water is absorbed.

**DRY ITALIAN SAUSAGE** Take 5 lb. freshly butchered ground pork butt, 2 t. black pepper, 1 clove garlic (chopped), 1 wine glass of red table wine, 1 T. salt, 1 T. fennel seed, and 1 t. ground hot pepper. Blend well and store in refrigerator overnight. The next day, stuff in casings. Then freeze, or hang up to dry in cool, ventilated room for 1 week and then freeze. Some people add ground onions to sausage.

**ROSEMARY SAUSAGE** Take 1 lb. pork, 1 lb. beef, 1 lb. veal, 1 lb. suet, 1 T. salt, 1 t. black pepper, 2 t. rosemary (ground or chopped), 1/2 t. thyme, 1/2 t. marjoram, 1/2 t. freshly grated nutmeg, and casings. Finely grind first 4 ingredients. Add remaining ingredients and mix well. Put into casing and tie every 4 inches, or form into patties and refrigerate.

**DUTCH “POUTDEN”** Use a Dutch oven or a large pan with a cover. Cut or chop up the following ingredients, working from the bottom of the pan to the top. On the bottom make a layer of potatoes, then carrots, then onions, then apples, then cabbage (cut in chunks), and then mettwurst or any good smoked sausage (cut in small pieces). Add 1 to 2 c. water, salt, and pepper. Boil until mushy. Can be served as it comes or mashed together.

**SWEET AND SPICY SAUSAGE** To 4 lb. pork trimmings, add 3 t. salt, 4 t. sage, 2 t. black pepper, 1/2 t. ground cloves, and 1 t. sugar.

Canning Sausage. See the Ground or Chopped Meat recipe in the “Canning” section.

Preparing Hamburger or Sausage to Be Frozen. Mix together your desired meat, fat, and seasoning ingredients. Then decide if you want to freeze it in clumps, patties, or rolls. For clumps, divide into the sizes you want, wrap, label, and freeze. For patties, divide meat into 1/2-lb. balls and press into flat patties (or use a hamburger press). Package for freezer the desired number of patties per package. Separate the patties by a double thickness of wax paper. Wrap, label, and freeze. When thawed, these patties can be broiled, pan-fried, or baked in gravy. For rolls, shape meat into cylinders of a diameter and length that will feed all of your family for 1 meal. Wrap, label, and freeze; when you defrost it, cut into slices. Rolls slice better if they have some fat content or if all-lean meat is mixed with a little water.

**Soups from Meat**

**CONSOMME:** Prepare for the pot a chicken that weighs about 4 lb. Saw about 2 lb. worth of beef bones into pieces. Cut up 2 lb. beef. Put everything in a covered kettle and add water to cover. Let it all soak an hour; then put over the fire and bring quickly to the boiling point. Reduce heat at once to simmering and cook 6 or 7 hours. In the last hour of cooking, add 1 T. salt, 1/2 c. carrots, 1/2 c. onion, 1/3 c. celery, 1 t. peppercorns, 2 whole cloves, 1 allspice berry, 1 small bay leaf, 2 sprigs parsley, 1 sprig thyme, 1 sprig savory, and 1 sprig marjoram. Cut the vegetables into reasonable-sized pieces. At the end of the last half hour of cooking, strain the soup. Then chill it. When it’s cold, remove any fat that has solidified on the surface. Clarify by reheating with 2 slightly beaten egg whites, stirring constantly until it boils. Boil 5 minutes. Then let stand until it settles. Strain through 2 thicknesses of cheesecloth.

**BOUILLON:** Use 3/4 lb. beef. Put in a pan with water and let stand an hour. Then put over heat in covered pot and bring to boiling point. Skim off scum. Reduce heat and simmer 3 hours. Chop 1 onion, 1 carrot, 1 sprig parsley, and 2 stalks celery and add to soup with 1/2 bay leaf, 2 cloves, 6 peppercorns, and 1 t. salt. Let simmer an hour more. Strain into a bowl and chill. Remove fat when it is firm and clarify for consomme.

**BONES:** No matter how closely trimmed, bones can be cooked for a delicious and nutritious broth. Fill a large pressure cooker or canner with trimmed bones, half-fill it with water, and cook at 15 lb. pressure for 1 hour. After the pressure has dropped, strain the broth into another kettle and pick off any meat still on the bones. Chill the broth and remove the fat from the top. The remnants of meat and broth can be either frozen or canned. Use the bones as dog
BY-PRODUCTS: SOAP AND TANNED HIDES

There’s no need to waste anything from your animals.

Soap Making

Soap is nothing more than a mixture of fats or oils with lye and water. Although soap has been a part of human life for at least the last 2,000 years, its commercial history is very short. Before people learned the connection between bacteria and disease and figured out that soap killed bacteria, cleanliness was not a popular concept. But by the mid-19th century, innumerable fat-lye soaps were on the market, some made with animal fats and others with palm kernel oil, which lathers more easily than tallow soap. These days, commercial soaps and detergents are so plentiful that homemade soaps are a handicraft.

The idea of making one’s own soap is attractive for several reasons. First, it is the only way to really know what you are rubbing on your hands or soaking your clothes in. Makers of commercial soap detergents don’t list all their ingredients on the package. Those of us who are concerned about ecology have to dislike the detrimental effects of the commercial synthetic detergents that have been widely used since just after World War II. (Although soaps in large concentrations can poison marine life, this rarely happens because the soap decomposes readily.) Second, soap is another use for the by-products of slaughtering your animals, making the proposition of raising stock that much more economically efficient. Third, the cost of making homemade soap is much less than that of buying commercial soaps.

Homemade soap leaves clothes with a lovely clean smell. (Use about 1 1/2 c. per load, or more if you’re planning on putting a lot of clothes through the same water.) I like homemade soap for dishwashing, too. Here’s my testimonial: my glasses have been shinier and my silverware sparklier since I started washing them with homemade soap. I can also see the soap in the rinse water for the dishes because it turns gray very quickly—an advantage over detergents, which are so clear that you think you have washed them away, but you end up eating them! Homemade soap works okay in lukewarm water if you can give a halfway ample hot rinse. It’s also fine for human bodies if it is properly aged. You can wash your face and take baths with it. You can use the leftover water to irrigate garden or flowers, since the soap has no additives that harm the environment. And homemade soap is a bargain!

If you wonder what using homemade soap flakes is like, just buy some White King. As far as I can tell, it’s identical to homemade! Of course, homemade soap doesn’t contain the bleach that is present in so many detergents now, so your clothes won’t look “white” unless you add a bleaching agent separately to the water. Or you can make your soap with bleach. Homemade soap won’t work well in a very hard water unless you use some borax to hold down the “curding.” You can put borax in when you make the soap. Using liquid bleach will also help hold down the curds.

Books on Soap Making: The Art of Soap Making: A Complete Introduction to the History and Craft of Fine Soapmaking, by Merilyn Mohm (1979); Dorothy Richter’s Make Your Own Soap! Plain and Fancy (1974); and The Natural Soap Book, by Susan Miller Cavitch, are available from 719-962-3228; www.cfamilyresources.com. Milk-Based Soaps, by Casey Makela; The Soapmaker’s Companion, by Susan Miller Cavitch; The Handmade Soap Book, by Melinda Coss; Making Natural Liquid Soaps and Making Transparent Soap, both by Catherine Failor; and Melt & Mold Soap Crafting, by C. Kaila Westerman, are available from Storey Books (address in Chapter 1).

The most recent is Elaine C. White’s Soap Recipes: Seventy Tried-and-True Ways to Make Soap with Herbs, Beeswax, and Vegetable Oils. Order her book from Valley Hills Press, 1864 Ridgeland Dr., Starkville, MS 39759 ($24 postpaid).

Soap-Making Supplies: A homemade bar of soap can be a work of art and/or a way of making money.

K & W Popcorn ships 5-gal. coconut oil or 35-lb. bags: 816-359-2030; PO Box 275, 710 E. 24th St., Trenton, MO 64683.

Liberty Natural Products, 8120 SE Stark St., Portland, OR 97215, 800-289-8427; fax 503-256-1182; www.libertynatural.com. Wholesale only; $50 minimum. They sell essential oils, soapmaking fats, herbs, clays, etc.

Lorann Oils offers molds for soap and candies, essential oils, flavorings, and specialty ingredients for soap-, candle-, and food-crafters: 4518 Aurelius Rd., Lansing, MI 48910; 800-862-8620; fax 517-882-0507; customercare@lorannoils.com; www.lorannoils.com.

SunFeather Natural Soap Company, 1551 State Hwy. 72, Potsdam, NY 13676; 800-771-7627; fax 315-265-2902; www.sunsoap.com, offers soap-making books, supplies, and equipment. Free color catalog.

Hot Water, Cold Water, Hard Water: Homemade soap is good for washing if you are able to wash in hot water. It isn’t good for washing dishes or clothes in cold water, though, because it doesn’t dissolve easily, even if you make it into soap flakes. If you use it to wash dishes in hard water, it leaves a ring around the sink. Hard water contains calcium, magnesium, and iron, which, with soap, form compounds, or “curds,” that resemble sticky gum. Use borax or washing soda to soften hard water before adding soap. Make sure the soap is dissolved before you add clothes or dishes. Otherwise you risk having little particles of undissolved soap left among your clothes. A really good hand rinse will easily get rid of those particles, but automatic washers aren’t built to handle that. You’ll have to
agitate the water to dissolve the flakes into solution and produce suds. Use water as hot as your hands can stand—or hotter. Great-Grandmother literally boiled her clothes with homemade soap in a big iron pot over a fire in the backyard on washday. But then, practically everything her family wore was cotton.

**Soap Jelly:** You can solve the dissolving difficulty by heating, or adding hot water to, a concentrated soap mixture, stirring it into solution, and then cooling. The old-timers called this dissolved soap “soap jelly” and made it ahead. They used it in washing machines and for washing dishes because soap jelly easily melts in hot water and makes thick suds. To make soap jelly, you cut 1 lb. hard soap into fine shavings and add 1 gal. water. Boil about 10 minutes and then cool. Keep soap jelly covered to prevent drying out. A reader told me an even easier way. She puts homemade soap bars into a few gallon glass jars and pours hot water over. Every day or so she drains off the liquid into a plastic pail, and that liquid is soap jelly.

**Buying Lye.** You can buy lye from the cleaning agents section of a regular supermarket. If they don't carry it, ask. They can order it for you. It may be called sodium hydroxide or caustic soda. Store lye is sold in cans, usually containing about 13 oz., under several different brand names. Note the sodium hydroxide content. It should be 94–98 percent. Lye for soap is different from the lye used for drain openers, which has nitrates and other additives. There is usually a soap recipe on the lye can. Most lye companies will send you further information on soap making upon request.

**Making Lye.** Use ashes from hardwoods, if possible, such as oak, walnut, or fruit wood, since they make a stronger, better lye. Pine, fir, and other evergreens are soft woods. Put the wood ashes in a barrel with a small opening near the base to let the water “leach” through. Set the barrel so that you can put a container under the hole. If your wooden tub or barrel doesn't have a hole, bore one with a drill on the side near the bottom of the barrel. Before putting in your ashes, put several clean rocks or bricks inside the container by the hole and then add a generous layer of straw, if you have it—hay or grass, if you don't. Then you can add your ashes. You can just let them accumulate until you want lye or until your container is full. The most efficient way of proceeding is to then add soft water to your barrel until water begins to run from the tap (this may take awhile). Then plug the tap hole with a cork plug (home brewer's supply houses have them) or something, and let it soak a few days. If you have extra ashes, you can add more ashes and water as the first layer settles in the barrel from the wetting. In 3 days, open the plug and have a wooden tub, crock, or glass container ready to catch the trickle of lye water emerging from the opening.

**Lye Concentration.** Store lye is just fine if you follow the directions. For homemade lye, put in an egg or potato. If it floats enough that a piece about the size of a quarter is exposed on the surface, the lye is about right for soap making. If it sinks, the lye water needs to be leached another time through fresh ashes or else boiled down until the concentration is strong enough. If your lye isn't strong enough, you'll make soft soap as the pioneers did. Knowing how much homemade lye to use in soap making requires experience. Excess lye makes a coarse, flinty soap that will crumble when shaved and burn you when used. Soap should have a smooth, velvety texture that curls when shaved. If any free lye is present, the soap “bites” when touched with the tongue.

**Fats for Soap:** Since soaps and candles both use tallow, pioneer families often produced both at the same time. The grease must be pure, clean, and fresh (or frozen) to obtain soap with a clean, wholesome odor. By “toilet” soap, the old-timers meant soap using fat from butchering rather than drippings; it was a whiter, better-quality soap. “Saddle soap” meant an all-mutton or beef tallow soap. Such a soap was valuable as a cleaner and preserver of leather.

Six pounds of fat and 1 can of lye will make about 9 lb. of soap. Mutton (sheep) or goat tallow (fat) is the hardest of all animal fats, having the highest melting point. Used alone, mutton or goat fat makes a hard, dry soap unless you add extra water or mix the hard fat with softer ones like lard, goose grease, or chicken fat. Beef tallow, once the preferred fat for soap, is next in hardness and also should be mixed with softer fat or additional water. One pound of untrimmed beef fat will get you 1 c. tallow. Lard (pig fat) makes fine soap, giving you 2 c. fat for every pound of meat, although it may be a little soft. Poultry fat is too soft when used alone, so it should be mixed with harder fats. Meat fryings, cracklings, meat trimmings, and other refuse fat must be first clarified and desalted.

You can use any animal or vegetable fat (even salad oil), but not mineral oil. Tallow alone produces a hard soap without much lather. Adding vegetable oils improves the texture. The best vegetable oil by far is coconut oil, which produces a fine sudsing soap similar to a “shaving” soap. (All-lard soap is similar; you can use the coconut oil soap recipe to make it.) Soap made from vegetable oils or soft fats requires less water and needs to dry longer than soap made from tallow. Cottonseed oil is difficult to work with and results in a soft soap, while olive oil is better for soap making than other vegetable oils.

Store your fat in a cool, dry place while you accumulate enough for soap making. When you do have enough,
make it into soap promptly, because fat will become rancid over time, and rancid fat has to be cured of that problem before it can be used (more on that later). Soap improves with age; fat doesn’t.

To accumulate fats, each day save your fats of all kinds. If you boil meat, cool the pot of liquid and remove the fat. Then put the accumulated fat on and melt it. Cook long enough to get all the water out (if you don’t, it will mold or spoil). Then fold several thicknesses of cheesecloth or any loose-weave cotton, and strain the melted fat. Always be careful when handling hot fat, since it can burn you. Keep all fat in a tightly lidded pan, away from any strong-smelling stuff, until you are ready to make soap. You may want to freeze it, but if you can store it in a cool place, it will keep for several weeks.

**Rendering Fat.** Render any surplus fat from butchering or fatty trimmings from cutting up. Grind the fat or cut it into pieces. Put it into a large kettle on top of the stove or in a large pan in the oven. Add about 1 qt. water for each 10 lb. fat. Use a moderate temperature and stir occasionally. When the fat is liquefied and the solids (cracklings) are brown and settling, carefully strain the fat. You may want to do this more than once. Your soap will be as white as your fat is. If your fat is not pure enough, you may end up with yellow smelling stuff, until you are ready to make soap. You may want to freeze it, but if you can store it in a cool place, it will keep for several weeks.

**Clarifying Drippings and Removing Salt.** Put the leftover cooking grease into a kettle with an equal amount of water. Use a large pot so it won’t be likely to boil over. The day before soap making is a good time to do this. Bring to a boil, stir, and add 1 qt. cold water for each 1 gal. drippings. Stir to break up any lumps. When the water boils, let it set and settle. Then cool and skim fat from surface with skimmer, or refrigerate and clean the cake of fat as described above, or strain. Repeat these procedures until you are satisfied with the condition of your grease. I would advise not even bothering with leftover grease that has absorbed strong smells, but sometimes you can cut the effect by adding a little lemon or vinegar to an amount of water equal to half the amount of fat and boiling them together. (Soft fats that won’t get firm even when refrigerated have to be skimmed, of course.)

**Removing Rancidity.** Boil the sour or rancid fat in a mixture of 5 parts water to 1 part vinegar. Cool and skim fat, or refrigerate and remove fat cake. Remelt the fat; for each gallon of fat, add 1 qt. cold water. Stir slightly. Cool and skim fat or remove fat cake. Repeat as necessary. Fat that is rancid is fine for soap making but not for eating ever again.

**Other Soap Ingredients**

**Water.** Water is a basic ingredient of soap making. You need pure water, free of chemicals that can combine with the lye. Don’t use hard water unless you neutralize the chemicals in it with washing soda. “Hard water” means water with minerals dissolved in it. Rainwater isn’t hard, but almost all water from springs, wells, or rivers is, in varying degrees. Measure the water into enameled, wooden, or crockery containers that are easily handled.

You can test how hard your water is by making a solution of denatured alcohol or wood alcohol and pure soap. At room temperature, mix in soap a bit at a time until the solution is nearly thick. Then find 2 identical small medicine bottles or spice containers. Put rainwater or distilled water in one and the test water in the other. Use an eye dropper to add soap solution to the distilled water. Shake frequently. The idea is to get suds to cover the water surface for 1 minute after the bottle is laid on its side. If you then add the same number of drops to the test water, shaking, you can see how long the suds last there. Soft water will produce a minute’s worth of suds; hard water will not.

**Perfume.** Perfumes like oil of sassafras, oil of lavender, and oil of lemon may be added to soap. They used to be cheap, but not any more. Oil of citronella is sometimes suggested, but I wouldn’t use it. It’s an excellent insect repellent, however. Never use perfumes containing alcohol—they will not last and may cause separation. Experiment to learn just how strong you want your soap to smell. For a start you might use, per 15 lb. tallow: 4 t. oil of sassafras; 2 t. oil of lavender; 1 t. oil of lemon; 1 t. oil of cloves; 1 t. oil of almond; 2 t. oil of pine; or ¼ t. rose geranium oil.

You can make your own rose geranium perfume by making a tea of the rose geranium leaves and adding it to your soap. All soap readily absorbs odors, desirable or undesirable, so it can be perfumed simply by placing it with the petals of any favorite flower or perfume, if you have yet not added a scent.

**Coloring.** Uncolored soap is fine. A light yellow or marbled effect can be made with liquid butter coloring. You can make your own pink coloring by adding an extract of the blossoms of pink roses or tulips. A green color can be had by pounding the tops of beets (or spinach, parsley, etc.) to extract a few drops of the juice and adding it to the water. (For more ideas, see the section on making food colorings in Chapter 5.)

**Borax.** Borax quickens the sudsing action of soap because it helps to hold down homemade soap’s tendency to curd in hard water and it’s a natural fabric softener. Because they used borax, the old-timers could hang their clothes on a line and they’d come out soft.

Since chemically, borax doesn’t play any role in the soap recipe—it’s just a physical additive—using more or less doesn’t affect the quality of your soap a bit. I’ve seen recipes with anywhere from 2 T to 3 c. borax per can of lye. You can buy it at your grocery store. The exact amount you should add depends on how hard your water is. You can make a batch one way and see how it washes, and then either add or subtract borax the next time according to what you learn. Or you can leave the borax out of the soap recipe completely and add it at the time you wash clothes. That will give you a good notion of just how much borax to include the next time you make soap.

**Air.** If you want your soap to float, fold air into it when it begins to have a creamy consistency. You fold in air just as you would fold an egg white into a cake mixture. Test for floating by flicking a few drops on cold water.

**Rosin.** Adding rosin to soap increases its lathering ability but makes the soap darker and softer. Rosin soap is okay for laundry. Add 8 oz. crushed rosin to ½ lb. fat and heat until the rosin melts or is dissolved in the fat. Cool fat to 100°F and add 90 lye solution made of 1 can lye dissolved in 2½ pt. water.

**Saponification:** Soap making is a chemical process.
When lye and fat are brought together under the right conditions, they react to make soap, which is an alkali salt of fatty acids and glycerin. The process is called “saponification.” It may take several weeks for complete saponification to take place. This is one reason that aging is so important in soap making. Soon after it is made, soap actually contains some free lye, but the longer it ages, the less likely it is to contain any free lye. Soap made from lard or soap that has been boiled requires longer aging before it becomes hard and ready for use. Once it is saponified, the soap will never separate into fat and lye again. In homemade soap, the lye is left in. In commercial soap making, it is separated and sold.

**Lye to Fat to Water**

To make good soap you need correct proportions of these basic soap ingredients.

**Cold Process.** The process I use to make soap is the cold process. To make the very best soap (mine is not), use exact weights, measures, and temperatures. A dairy (floating) thermometer and household scales are useful. Soap has to have the right proportion of fat to alkali. Too much fat makes for an ineffective emulsifier, but too much alkali will make soap that’s too harsh, especially for skin. The saponification has to be nearly complete. Free fat can become rancid, smelly brown spots on your soap. Free bits of lye can burn the skin.

Combine lye, water, and fat (see “Lye to Fat to Water” table for proportions). First add the lye slowly to your water when making a solution from the lye crystals, and then add the lye solution slowly to the melted fat. Stir evenly, preferably only in one direction. Rapid addition of the lye to your fat, or of the fat to the lye, can cause separation. So can jerky, uneven stirring. Boiled, or hot-process, soap is probably superior to the kind I describe here, but it’s a lot trickier to make. Use an enameled kettle, never aluminum.

Confused already? This will help.

**The Basic Steps of Soap Making**

1. Slowly add 1 can lye to 5 c. cold water in an earthenware or unchipped enameled or “ceramic on steel” container. Steel or aluminum under the enamel is okay. Don’t use cast iron. Ask at a kitchenware store or at a homesteader’s supplier if you are not sure what pot to use.

   Mix lye and water outdoors or near open windows, because the mixing produces heat. There will be strong fumes that you can see. Try not to breathe them; they’ll make you cough. Don’t use anything but a wooden spoon to stir. Be careful not to splash it on your skin. Stir constantly until the lye crystals are all dissolved. Now let it cool. Cool the lye solution to 70–75°F if your fat is lard (pig fat), 90–95°F for an all-tallow soap.

2. Heat 10 c. melted fat. A relatively large proportion of fat gives you a milder soap. If the temperature of the lye water (including borax if it’s in your recipe) is about 75 to 80°F at the time of mixing with the melted fat, the fat should be heated to the appropriate temperature, as shown in the “Heating Fat” table. Too high a temperature darkens the color of the soap and may keep it from setting.

**Heating Fat**

3. Pour the fat slowly into the lye water when you have each at the right temperature.

4. Add your borax, perfume, coloring, or other extras at this point.

5. Stir in one direction until you have soap. This usually takes about 15 minutes, but it could happen in 5 minutes or take an hour, depending on temperature. If you have waited for your ingredients to cool, you should have no problem. If you’re having a setting problem, you might try setting the mixing container in cold water. If, on the other hand, the soap starts setting on the edges, stir faster or even beat it. Soap starts out dark-colored; as you stir, it gets somewhat lighter in color. When all the lye gets mixed with all the fat, saponification happens. You’ll notice a cloudiness first. It’s ready to pour when it is like thick pea soup, and drops that are trailed from the spoon stand momentarily on the surface of it. It’s also ready if the stirring spoon will stand by itself in the middle. If you pour too soon, the soap may separate into 2 layers, the bottom hard and brittle and the top greasy. But if you wait too long, you’ll end up with incomplete, odd-shaped bars with air pockets.

6. Pour into molds. Scrape all the mixture out of the bowl. Your soap will be a little dark when first made but will turn white in a week.

This sounds like a lot of work, but it isn’t after you make a couple of batches. All these little things will soon come naturally. There are infinite variations on this procedure, but it’s the one I know best and it’s relatively simple. It makes a good basic raw (cold, not cooked) soap for soap flakes with which to wash dishes and clothes. But later on, I have some even easier ones for you that readers have sent me.

**Soap Molds:** What you can best use for a mold depends on whether you’re planning to make soap flakes or bar soap. For soap flakes, you can use anything except metal containers for a mold—serving bowls, enamel pans, wooden boxes, plastic containers, and cottage cheese cartons (handy because you can cut them off when you’re done). Avoid containers with paint or dyes that the soap could absorb. Have your molds ready before you start, and expect to dispose of them once the soap hardens. Grease
Bar soap may be neatly cut with a wire

Grate thoroughly aged soap for soap flakes

1. Lye is caustic soda. It burns, even in tiny flakes. Lye in the eyes or on skin or clothing can cause severe burns. Obviously, you should not swallow it.

2. Keep children and animals away from lye.

3. The fumes of lye in water can burn your throat and chest. Work in a well-ventilated space, outside or near a window. Don't breathe the fumes!

4. Keep newspapers handy to sop up spills.

5. Don't keep lye or a lye solution in metal; lye reacts with metal. Don't put it in aluminum, because it will react with the aluminum. Don't put it in tin, iron, or stainless steel. It's best contained in plastic, glass, stoneware, or unchipped enamel.

6. Be careful with glass. Water and lye can heat enough to break glass.

7. Measuring spoons of stainless steel are okay, but cups should be glass or heat-resistant plastic. Utensils exposed to lye should be enamel, crockery, glass, or wood—and they should never be used for anything else. Rinsing utensils after they have been in a lye solution makes them safe to handle, but remnants of lye in cracks can contaminate foods.

8. Use only wooden spoons. A slotted spoon is good for stirring. Better yet, stirring with a piece of kindling will save spoiling a good wooden spoon.

9. Never add hot, or even warm, water to canned store-bought lye crystals. They heat up anyway when combined with water, and the hot water will cause spattering.

10. For protection when making soap, wear rubber gloves and keep a bowl of vinegar nearby, so if you spatter lye on your hands or arms, you can dip them immediately into the vinegar to neutralize it.

First Aid for Lye Burns
Be extremely careful when working with lye. If lye comes in contact with human skin, it causes a chemical burn. Flush immediately with water. If it is not flushed, it will continue to burn. If possible, add a little salt to the water. If water is not available, use soda water or soda pop—they're better than nothing. If, after 5 to 10 minutes your skin is still red and painful, seek burn care in a hospital emergency room.

If lye is swallowed, call 911. Swallowing lye can be fatal. When swallowed, it burns the esophagus, so vomiting (which may be inevitable) should be avoided. Take milk or ice cream to help neutralize the lye's chemical reaction. Although vinegar, orange juice, and so forth also neutralize lye, they should not be ingested because the combination creates heat. This rise in temperature will burn physically in addition to the chemical burn.

If lye gets into the eye, call 911. Flush the eye immediately with water; add salt to the water if possible. Again, use milk if available, to neutralize the chemical reaction. Most likely you should get to an emergency room as soon as possible. Do not use vinegar or boric acid solution.

But the best advice is: Be Careful!
a rug or blanket to retain heat while the soap is texturing out. Some people cut the blocks into bars only a few hours after pouring. If you do this, be careful. The saponification is probably not complete, and the lye in the solution can still burn you. Some people prefer to leave the soap molds undisturbed for at least 24 hours before cutting and piling. Others take a knife and score the soap into bars a few hours after making, let it sit overnight, and then turn them out on a board and finish breaking the cuts so the bars will separate nicely. When well set, remove the soap and cut into convenient-sized cakes. To remove the soap from a mold made of a damp box lined with cotton, just lift the soap by the ends of the overhanging cloth lining. Pile the bars on top of each other so air circulates around each cake. The soap can be neatly cut by wrapping it once with a fine wire such as piano or guitar wire, crossing the ends, and pulling.

Many of the commercial molds for decorative candles can be used to make soap too. Just avoid the metal ones. Those molds that shape the top of the soap must be pressed tightly since soap hardens more slowly than wax, especially in a closed mold. Remove the soap before it is completely hard so you can smooth the edges and fix any small flaws. Remember that the soap is still fairly caustic at this stage.

**Soap on a Rope.** Double a washable cord and wrap the ends with thread for 2 inches. Stick this end into setting paste. Or pour into a mold and, when hard, cut into cakes. Or you can add 5 to 6 lb. of the abrasive to the regular soap mixture when it thickens, and stir until thoroughly blended.

**FLOWER SOAP** Take 4 packed c. fragrant flowers (such as rose, cherry, or apple), 4 c. rendered tallow, 2 c. cold soft water, vegetable oil, and 1/2 c. plus 2 T. lye flakes. Gather flowers just before you make the soap. Immerse them in the melted tallow. Heat for an hour just at the melting point. Allow to harden overnight and then remelt (don’t overheat) and strain. Add enough vegetable oil to flower tallow to total 5 cups. Cool. Stir lye into cold water until dissolved. Grease molds with vaseline. Proceed to cool, mix, and mold as for any other soap.

**CASTILE** SOAP This one is a very high-grade soap: use 24 oz. olive oil, 38 oz. good tallow, and 24 oz. coconut oil. Have fats at 90°F. Use 1 can lye and 2 pt. water cooled to 90°F. Follow basic soap-making procedures to complete.

**COCONUT OIL SOAP** A pure coconut oil soap gives a very profuse but thin lather. For a thicker lather, use part tallow. Pure coconut oil soap is made by using 1 can lye, 4 1/2 lb. coconut oil, and 2 1/2 pt. water. Have lye solution at 70°F; oil at 130°F. Follow basic soap-making procedures to complete.

**MYSTERY PALM OIL SOAP** This recipe was sent to me by Randee Greenwald, a Peace Corps volunteer working in Cameroon, a country in western Africa. Like many Westerners in non-Western settings, Randee wrote me to say this
book had been useful and to help me make it more so. She shared her soap recipe, adapted to the local village economy. This recipe requires 5 liters water, 5 liters palm oil, and 500 grams (17.5 oz.) caustic soda. (A liter is just a bit more than a quart) "Palm oil can be produced in the villages. The oil has to be cooked first. It takes anywhere from ½ hour to an hour to cook out all the impurities. It must then be allowed to cool awhile. The caustic soda must be bought in town. Using a plastic bucket, add the caustic soda to the water and stir until it's dissolved. Let it cool for a couple of minutes and add the oil."

Now here this recipe runs into a problem. A mouse chewed off a bit of the edge of the letter during the years I stored it waiting to write this new edition. After the gnawed-away place, it continues: "... ached [be bleached?] first—and takes anywhere from ½ hour to an hour to cook out and stir... [another mouse-eaten chunk, blank?] with a wooden stick. This takes quite some time—an hour or more. You know when the soap... [is done?] when your arms break or when you stop and it does not separate. You can leave the mixture in the plastic bucket or pour it into molds. It takes about 3 weeks to dry." (Anybody who can supply the mystery words, I'd love to hear from you!)

**Natural Sudsing Agents:** A number of plants (mostly tropical) produce a substance called saponin that can enhance the sudsing quality of handmade soap. Saponin is commonly obtained from soapbark, a South American tree, but a few saponin-yielding plants grow in the northern United States and Canada as well. *Saponaria officinalis*, a common weed known as chimney pink, soapwort, bruisewort, bouncing bet, or latherwort, has an abundance of saponin in its roots. It has dense pink and white flowers in late summer and early fall. Although all parts of the plant have saponin, you can dig up the roots and crush them in water to obtain a foam that is good for cleansing silk and wool. Another plant that has saponin is *Saponaria ocymoides*, a small pink-flowered perennial. Sweet pepperbush, a species of white alder, grows along the coast in the United States and in lower Canada, mostly in swamps. Lamb's quarters, a summer weed, also has the soaping agent. And finally, quinoa growers have to get rid of the saponin before eating their grain. To extract saponin, crush or grind the plants, boil them in alcohol, and strain the hot liquid. While it's cooling, it will produce a white crumbly powder that easily sudses in water.

**Tanning**

Animal skin, when fresh and unworked, has 3 layers. The outer skin is called "scarf skin" by tanners; it comes off with the hair. The middle skin is called "grain." The underskin is called the "flesh." The scarf skin peels off naturally. The flesh you scrape off. The grain is what, combined with tannin or other substances, produces leather. Grain is made up of interlaced bundles of gelatinous fibers more or less filled with fluid matter. In the tanning process the fluid is eliminated, leaving only the fibrous portion that can be affected by the tanning substance(s). The loss of this fluid is what reduces the weight of the skin.

Tanning is a long, hard process. Sometimes you may be more successful than others. Some techniques may suit you better than others. The ways to do it are as varied as the end products. When you tan a skin, you're converting an easily decomposed substance, skin, to one which resists putrefaction—leather.

**Tanning Supplies and Services:** To ship a hide, put it into some sort of mailing container and send by motor freight, parcel post, or UPS to the tannery of your choice. Include instructions for what you want done to it.

**Braintan.com** equals Matt and Michelle Richards. They sell books, tanning supplies, tools, and info on making buckskin, leather, and furs. 10398 Takilma Rd., Cave Junction, OR 97523; matt@braintan.com; www.braintan.com; 541-592-3693. Their amazing website contains 250+ pages of articles, tutorials, an online, ongoing forum, sources for tools, books, videos, finished skins, and more traditional tanning info than you knew existed.

**Bucks County Fur Products** tans to order (send SASE): PO Box 204, Quakertown, PA 18951. No phone, but good service.

**Eagle Feather Trading Post** offers pre-1800 patterns for homemade buckskin clothing, Indian craft supplies, Mountain Man, rendezvous, and survival supplies: egi-crafts@aol.com; 801-393-4555; 6756 North Fork Rd., Liberty, UT 84310; www.eaglefeathertrading.com.

**Hanson's Leather** sells supplies, tools, patterns, and books for making traditional leather clothing and goods: 6900 Andressen Rd., Sheridan, CA 95681; 530-633-0844; fax 530-633-0193; hansons@succeed.net; www.hansons.net.

**The Leather Factory** sells leathers, tools, books, saddle and tack hardware, supplies for repairing shoes, etc.: PO Box 50429, Ft. Worth, TX 76105; www.leatherfactory.com; 800-433-3201.

**Stern Tanning Co.**s Jeff Stern will gladly tan your hides: 920-467-8615; fax 920-467-8694; PO Box 55, 334 Broadway, Sheboygan Falls, WI 53085; sterntanning@powercom.net.

**Tandy Leather Co.** sells leather-working supplies: leathers, tanning kits, tools, dyes, hardware, and books, including Stohlman's encyclopedia series on the manufacture of leather products: 808-890-1611; PO Box 791, Fort Worth, TX 76101; www.tandyleather.com.

**Van Dyke's** offers a wide variety of tanning chemicals, oils, softening and pickling agents for home or commercial use, plus a complete line of tools, fleshers, leather, felt, and accessories. Free mail-order catalog: 800-843-3320; Woonsocket, SD 57385; www.vandykes.taxidermy.com.

**Info on Tanning:** Subscribe to The Leather Crafters & Saddlers Journal to network and learn about serious leather-working: supplies, patterns, machines, step-by-step instructions, etc.: $29/yr for 6 issues: 715-362-5393; 331 Annette Ct., Rhinelander, WI 54501-2902; journal@newnorth.net. You'll find good directions for tanning sheepskins in the Spring 1984 issue of The Black Sheep Newsletter, available for $1.95 from Shepherd magazine (address in Chapter 11, "Bee, Rabbit, Sheep, and Pig.")

Lotta Rahme, describes the traditional tanning methods of Canadian Native Americans and the Sami Laplanders in northern Sweden: $19.95; call/fax 503-735-3942; 7549 N. Fenwick, Portland, OR 97217; tcl@teleport.com; www.teleport.com/~tcl. Primitive Wilderness Living & Survival Skills, by John and Geri McPherson, describes dry-scrape brain tanning in chapter 1 of their excellent book.

The Shoe Trades Publishing Co. publishes and/or sells the Leather Manufacturer Directory and many books on leather processes such as Manual of Shoemaking. The Fundamentals of Leather Manufacturing by Prof. Dr. E. Heidemann is a new book that covers the great extension in tanning knowledge of recent years: collagen, keratin, and elastin chemistry; mechanisms of enzyme action; microbiology; chemistry of vegetable and synthetic tanning stuffs, fat liquors, and dyestuffs, etc. The Leather Technician’s Handbook by J. H. Sharphouse is the newly revised text for England’s famous “Leathersellers College” written by world-renowned leather scientists, dealing with all steps of the tanning process. Shoe Trades Publishing Co. also offers Theory and Practice of Leather Manufacture and the Complete Handbook of Leathercrafting: 617-648-8160; PO Box 198, Cambridge, MA 02140-0002.

**The Basics**

**Vocabulary**

Bating solution: A solution for neutralizing the hide after dehairing in limewater.

Buckskin: A dehaired leather tanned by Indian methods.

Dehair: To remove hair from the hide. You have a choice of several dehairing methods.

Flesh (v.): To scrape off every bit of meat, fat, and “flesh” from the hide. (See “Fleshing” section.)

Green hide: An untanned hide.

Hide: The skin of a large, adult animal.

Hide-relaxing compound: A do-it-yourself formula is to wash and soak hide in hot borax solution until you can feel it’s not so stiff.

Neat’s-foot oil: Fat skimmed off after hoofs and hide trimming have been boiled down in water for so many hours that they set solid as a “gelatin.” (You can get it from a shoe store.)

Pelt: A sheepskin.

Prime: Of skins that you want to keep the hair on, from an animal killed during the cold months.

Rawhide: A leather produced without chemicals—not truly tanned, because it is never very pliable except when wet.

Salinometer: An instrument that measures the salt concentration in your solution.

Scarf skin (striffin): The outer layer of the skin. It cannot be tanned.

Scores: Cuts.

Skinning and Storing.

**Skin Weights.** The kind of leather that you can make depends on the size and weight of the skin you start with. Commercial tanneries have equipment that can split a heavy hide into layers of lighter leather, but you can’t do that without a special shaving tool available from tanning suppliers. So if you want light leather for gloves, bags, or garments, you have to start with the skin of a small animal such as a sheep, calf, goat, or deer. The finished leather is generally just a bit thicker than an untanned hide. The hide of a full-grown cow will start out weighing 60 lb. or more (which is a word to the wise about just what sort of a job it is hefting one of those around to tan it!). To make heavy belting, shoe-sole, or harness leather, you must start out with a hide weighing over 50 lb. Lace leather, small belting, and straps are made from a hide of 20 to 40 lb., which would be the skin from a light- to medium-sized cow. Calfskins, which average around 7 or 8 lb. in weight, are used for boot and shoe uppers and heavy gloves.

**Season.** The season affects the ultimate use of the skin, too. The best leather comes from animals taken in the summer and fall. Winter hides are less firm and are weakened by having grown all that hair, and the hair is just an extra chore if you don’t want it. On the other hand, the best hair-on skins are those taken during the winter, when the animal has its heavier winter coat of fur. A fine, fur-bearing skin would be tanned to take advantage of the fur.

**Species.** Deer is not recommended for hair-on tanning because its hair becomes brittle and sheds. Angora goatskins are often tanned with the fleece on for rugs. With the hair and scarf skin off, they make fine light leathers. As for cowhides, rather than struggle with such a heavy hide all in one piece, tanners traditionally make big cowhides into 4 separate strips for tanning. The hide is cut down the back to make 2 halves. Then each half is cut again in the nose-to-tail fashion. The back strips are a heavier leather when finished than the belly strips. The splitting of the back strip from the belly strip is generally done at the break of the flank, which makes the back strip about twice as wide as the belly one.

**A Basic Overview:** Start small—for instance, with a few rabbit hides. It will take around 2 weeks to finish them. Here are the basic steps:

1. Soak in fleshing solution.
2. Carefully scrape off all bits of flesh, fat, and membrane without tearing the skin.
3. Soak a week in a tanning solution.
4. Dry them slowly at the same time as you work them by hand so they don’t get stiff (too quick a dry means you must rewet and start over).
5. Oil hide with neat’s-foot oil.
6. Store flesh side to flesh side for a month. Then they’ll be soft and ready to sew.

**Skinning and Storing.** Making leather or fur starts with properly skinning and storing your animal. If you plan to make a rug, the traditional way is to first cut the animal’s skin down the center of the belly, from the throat (below the mouth) to the base of the tail. Then cut along the inside of each leg, from the foot straight up to the belly cut, and remove the skin in 1 piece. (See “Skinning, Quartering, and Packing” under “Wild Critters” for skinning instructions.) If you want to do hair-on tanning, be careful not to get blood on the fur. If you are skinning in the woods in winter, you can wipe bloody places on the fur with snow to get them clean.

**Fleshing.** Once the animal is skinned, you must scrape all pieces of flesh and fat from the skin. If they are left on, the salt won’t penetrate and the hair will slip while in the later curing process. Special tools are advertised in tanning-supply catalogs, but you can use a knife. Just be careful not to
make holes in your hide. This is a preliminary, superficial operation, as distinguished from the more serious scraping that comes later.

**Freezing.** If you have a deep freeze, just pop the skin in there until you're ready for the next step. You can store a hide at 0°F for a month.

**Salting.** If you are planning to make home-cured rawhide or buckskin, don't salt the skin; otherwise, spread it out flat, fur side down. Dampen the hide if it has dried. Rub salt liberally into the flesh side of the skin, about \( \frac{1}{2} \) inch all over the hide. Be sure and get salt into all the crannies and especially in places where the hide is thick. If you have several hides, you can salt them in layers—that is, you can spread out a hide, salt it, then put another on top, salt it, and so on. You can use any kind of salt; fine table or dairv salt is best. The basic principle of salting is that you can't use too much salt. Then roll the skin(s) up tight and let cure. The salting sets up the skin so that you can get right down to the hair roots when you flesh. *Always roll hides destined for hair-on tanning fur side in.*

For skins that you are planning to send to a mail-order tannery, just leave them rolled up to cure for a few hours. Then turn the scalp flesh side out, resalt, stretch, and partly dry in shade. *Never let skins destined for fur-on tanning dry in folds, as the hair will slip.* When partly dry, roll up flesh side out and ship at once. *Roll before skins get too dry and hard to roll.*

For skins to be tanned at home, store in a cool, dry place and leave the salt on at least 4 days. Seven days is better to hold the hides a second week. Shake, drain, resalt, and reroll. Don't store them too long. If they spoil, you've lost that skin, because it's just about impossible to get the bad smell out again.

**Drying.** Do this step if you are planning on storing your hide even longer, or if you are planning to send it to a mail-order tannery. Otherwise, skip it. For hair-on tanning, don't ever let the sun get on your hide, and don't let it dry in folds. Give the salted skin a good shake to get off the excess salt. For hair-on tanning, hang the skin to dry somewhere under cover. You can hang your hide by making a hole in it and putting a rope through it, or just by hanging it over something. After it has hung to dry a while, it turns white and gets progressively harder. The salted skin stores better if it is dried completely in the sun, but if you do that, when you get ready for the next step, you must resoak it from 1 to 6 hours in water and then give it a good scraping on the flesh side to remove the glue that otherwise would prevent your tanning solution from soaking into the hide. Scrape with a dull knife or broken glass.

**Tanning Recipes**

**Bark-Tanned Leather.** Old-fashioned bark-tanned sole and harness leather is the finest leather known, but it requires 120 lb. of finely ground oak or hemlock bark for each cowhide treated. I don't have the recipe, although I've heard it was in USDA Farmers Bulletin #1334.

**Unslaked Lime and Sulfuric Acid.** After a preliminary fleshing to remove large hunks of flesh and fat, the skin should be rolled up in salt (see "Skinning and Storing" section) for 2 weeks in warm weather, 3 in winter.

Then flesh it right down to the root hairs to remove all the tissue paper—like membrane. If you want your hide tanned without the hair, the next step is to remove the hair or fur. Otherwise this step can be skipped. Remove hair by soaking the pelt in a milk of lime solution. Put 6 to 8 lb. of unslaked (caustic) lime in a wooden barrel or plastic garbage can. Slowly add 1 qt. water and stir. Do not add so much water at one time that it stops the slaking action, and don't let the solution splash on your skin or eyes. (That will cause a burn.) If working in a plastic can, don't let the heat build up enough to melt the container. After slaking is complete, add 2 gal. clear cold water, mix thoroughly, submerge hide, and cover container. Stir 3 or 4 times daily and test hair each day. When the hair can be rubbed off (not pulled off), the process is complete. A deerskin requires about 3 days.

Remove the skin from the solution and scrape in the direction of the hair with a square-edged tool, such as the back of a knife. Scrape the hair uniformly, and wash out all the lime with fresh water. You cannot overwash it at this point. If you don't get the lime solution off, it will continue to eat up your hide. If you live along a creek, the ideal way to get rid of the lime is to hang the hide out in the riffle for 3–4 days. You can further neutralize it by soaking in a solution of \( \frac{1}{2} \) gal. vinegar to 20 gal. water.

The pickling solution is prepared by first filling a plastic container with as much water as necessary to cover the hide without crowding it. While stirring, slowly add 1 1/2 liquid oz. commercial sulfuric acid (65–70 percent) for each gallon of water in the container. (The Indians used urine as a pickling acid.) Do not pour water into the acid; it causes a violent reaction. (If any acid splashes on you, wash it off immediately.) Now stir in all the rock salt the solution will dissolve. Place the hide in the solution and move it around so that the solution reaches every part of it. Let it soak, stirring it daily for 4 or 5 days or as long as necessary to bleach the skin white. Test by cutting off a small strip of the hide along 1 edge to see if it is white clear through. Then wash it thoroughly and press it dry. (You can squeegee it out on your fleshing beam.)

Now take the amount of water that will completely cover the hide, and mix in as much baking or washing soda as the water will hold in solution. Soak the hide in this for an hour to completely neutralize the acid. When this is done, rinse out the soda solution thoroughly, and wring the hide out as much as possible by hand. Thoroughly rub the flesh side of the hide with a mixture of neat's-foot oil and beef tallow. Then wash the skin with cold water and detergent, and hang to dry again. When it is almost dry and still somewhat flexible, work the skin back and forth over the edge of a board or square iron bar, flesh side down, to soften it. Pull and stretch the leather in every direction until it is white, dry, and pliable. If the skin feels too oily, fine hardwood sawdust can be worked into it and then brushed off. Charlie Wilkes of Hillside, NJ, sent me that recipe, and I appreciate it.

**Salt-Alum Tan.** Before tanning a large hide, split it lengthwise down the center to make 2 easily handled pieces. Soak and cleanse the sides in a wooden or fiberglass tank (or a 30-gal. plastic trash can). Allow them to soak for 18 hours. Flesh the skins thoroughly, removing every bit of flesh, fat, and gristle. Remove the hair by soaking the skins in a solution of 10 lb. hydrated lime in 5 gal. water. Add more water to completely submerge the hide and soak the skins for 10 to 14 days. Move the skins around and stir several times a day. When the hair slips off easily by hand rubbing, remove the skins and lay them over a beam. Now you can take off the rest of the hair along with the thin top layer of skin in which the hair grows.
The salt-alum solution is widely used to tan leather. But if you don’t do it correctly, the leather may be stiff and hard; if so, repeat the process. Dissolve 5 lb. salt and 2 lb. alum in 5 gal. warm water, and then cool the solution before immersing the hide. Stir several times a day for 6 to 10 days. Tanning is complete when a thick sliver of skin cut from the edge shows the same light color throughout its thickness. Rinse the tanned hide thoroughly and hang to dry. Work the flesh side vigorously over the fleshing beam or the edge of the board. Keep the hide damp, and roll it up until it is pliable. This must be done several times until the hide is flexible as cloth. The final step is to rub a little warmed neat’s-foot oil into the dampened leather. Then work it over the beam once more. The product will be a leather than stays supple even when it gets wet.

Salt-Alum Dry Cure for Small Pelts. To get a long-lasting fur, you had best send your pelts to a professional tanner. But if you just want a simple home cure to give you a usable small skin, rub fresh skins (only the flesh side) with a mixture of 1 part salt and 1 part alum. Dry for 3 days in a cool shaded place. Remove all the dried fatty tissue and trim the edges of the pelts. Wash in a mild soap and rinse out suds. Don’t twist or wring. Hang the wet hides over a clothesline with the fur inside. Keep them out of the sun; it can stiffen them by drying them too quickly. Fluff the fur several times over the 2 or 3 days they take to dry. Rub neat’s-foot oil or saddle soap onto the skin side. The more you rub, the softer the pelt will be.

Salt-Alum Brine Cure for Small Pelts. Rub each skin thoroughly with salt. In a container, cover the skins for 4 days in a cool place. Take the skins out and scrape the skin side until all fat and gristle are gone. Mix 2 lb. salt, 1 lb. alum, and 2 gal. water to make the brine. (Double or triple if necessary.) Soak the skins in the brine for 2 weeks. Then wash them in soap or detergent and dry them on a line in the shade for 2 days. Fluff the fur several times and be sure the hide is completely dry before rubbing neat’s-foot oil or saddle soap onto the skin side. The more you rub, the softer the pelt will be.

Tanning a Snake Skin. Young Missy Kolb of Mt. Airy, MD, wrote me of shooting a copperhead that lay coiled up in her hours between paintings) for 7 days. On the eighth day it is. Some have very pretty colors and weight it heavily with rocks or blocks. Paint both sides skin out flat on a pine board. Put another pine board on top and let it dry out a little. Mix 1 part denatured alcohol and paint it on both sides. Then spread 1 part glycerine and paint it on both sides. Then spread the belly to show, in which case you split along

Shipping Hides. Put the hide into some sort of mailing container and send by motor freight, parcel post or UPS to the tannery of your choice. Be sure to include instructions.

Uses for Hair: Hair from hides is removed by the lime process described under tanning. If you want to use the hair for upholstering, wash it through several waters until clean, and then dry in a warm place. It may then be used to stuff cushions and couches as desired.

Rawhide: Rawhide and buckskin tanning (see next section) are the 2 processes most appropriate in a really primitive situation. The biggest drawback of rawhide is that after you’re all done, it can lose its shape if it happens to get soaked again. The biggest problem with home-tanned buckskin is that it smells bad.

You can make rawhide entirely of easily available natural materials. (You can’t use a skin that has been salted to make rawhide.) Properly speaking, rawhide isn’t “leather,” but it is potentially very useful. It is shaped when wet and then dried. Once it dries, it holds that shape and will be tight and hard. If something made of wood cracks or if you want to fasten wood pieces together with a nonmetal material, bind them with rawhide and then let it dry. Rawhide can be made into a rope by cutting in strips and plaiting. To plait rawhide, first soak the strips until soft. Keep them damp while you’re plaiting, and grease the rope after you’re done to keep it from getting too stiff.

You can also make buckets, baskets, or other containers from rawhide. Cut the rawhide to the shape you need. Then soak until soft and sew up, using thin strips of rawhide for thread. Fill with dry sand and let dry, or put over a wooden form that is the shape you want it to be and let dry. When dry, your rawhide container will be really sturdy. Now that you know what rawhide is good for, you might want to make some.

1. Get your hide. It’s most convenient to work with that of a small animal such as a calf. If the skin has already been dried, you’ll have to soak and scrape it until soft before proceeding.

2. Trim off unwanted flesh and fat with a sharp knife (don’t cut the skin!). Then use either the paste or container method to get the hair off. With the paste method, lay the skin, hair side up, on a clean surface and sprinkle about an inch of dry wood ashes over every part of it. Work the ashes well into the skin and then wet by sprinkling with the softest water you can get hold of—rainwater if possible. Fold the hide, ash paste and all, hair side in, into a tight bundle. Tie the bundle with a rope. Wrap with wet burlap that you can keep wet, or bury your hide bundle in moist earth. It will take about 3 days for the hair to loosen enough for the next step.

If you have a wooden or crockery container big...
3. Rinse the hide thoroughly. Proceed to dehair and flesh it. You need a surface to put the hide on and a scraper. You could buy a fleshing tool or make one. A table knife blade is the right kind of blade. If you can remove the knife from its handle and set it into a piece of wood, so you can have a handle on each side of the blade, you have a perfect fleshing tool. Lacking that, even a rib bone will work as a scraper. But if you're going to get serious about tanning, a good farrier's tool is worth having.

Fix yourself a beam to work the hide on. A log or half log (the round edges are the really important part) or even a 2 x 8-inch plank, rounded off, will do. Set the beam on legs at a 45° angle, bracing it well. One end can rest on the ground. Equip yourself with a bucket of water for rinsing. Throw the hide over the beam with the end falling off the tip, so you can press your body against the hide and hold it on the beam while your hands are occupied with the fleshing tool. Have the tail end of the skin toward you as you scrape to avoid catching your fleshing tool on the hair roots and cutting into the skin. Wear a waterproof apron and a pair of work gloves. (No one can scrape off the hair and scarf skin at the same time.

4. Wash the dehaired hide thoroughly. Stretch it to its full extent, and fasten for drying. You can nail it to the side of a building if you do it high enough so animals can't get at it. If you're planning to make a lot of rawhide or bucksins, rig yourself up a frame to lace it on. Make the frame out of wood strong enough to hold up against a good bit of pull and big enough to go around the outside of your stretched-out hide with room to spare. Then thread a 1/4-inch rope or what-have-you through the edge of the hide, then around the outside of the frame, back in and through the hide, around the frame again, and so on until you have the whole skin stretched. Keep your framed hide where animals can't get at it. If you find the hide stretching, keep taking up the slack until it is tight as a drum. Don't dry your rawhide in direct sunlight. Find a shady spot where air can circulate around it for best results.

5. When the skin is bone-dry, you have rawhide. For an extra, optional finishing touch, you could go over both sides of the skin with sandpaper, pumice, or sandstone to smooth down rough spots and give it an even texture. When you want to use some, just cut off what you want, soak 10 to 12 hours until workable, and shape as already described. Another way to soften rawhide is by making a mixture of 1 part neat's-foot oil and 1 part tallow, or use any animal grease and work it into the rawhide as you work it on your beam.

**Buckskin:** The best information on buckskin making is available from Matt Richards in his recent book, *Deerskins into Buckskins: How to Tan with Natural Materials, a Field Guide for Hunters and Gatherers* (10398 Takilma Rd., Cave Junction, OR 97523; www.braintan.com; $15 plus $3 s/h). Take a buckskin tanning class from River Spirit School of Natural Living, PO Box 173, Mad River, CA 95552. Like rawhide, buckskin is not, properly speaking, either "tanned" or a "leather." It's useless for harness or binding because it stretches so badly if wet. It tends to have an odor. On the other hand, it can be made relatively quickly without any store-bought stuff. It's soft as chamois but stronger and warmer than cloth, and it protects your skin against briars as well as denim does. You can wash it like cloth, squeezing the soapy water right through. Indians, hunters, and pioneers wore buckskin moccasins and clothes year-round, but it was considered low-class stuff.

You can make buckskin from deer, calf, sheep, or goat, but sheep isn't too desirable because it doesn't wear as well as the others. Deer and elk are the easiest to handle. Technically, "buckskin" means skin in which the grain fibers have been separated and softened by continuous pulling and stretching while drying, rather than by chemical action, and are preserved in that separated and softened condition by grease and by having been smoked. If buckskin gets wet it stiffens up again, but it can be resoftened by working with the hands.

1. Don't salt skins to be made into buckskin. Soak them in plain water until the hair rubs off easily. Keep the water in a warm place, if possible, and keep an eye on the skins so you'll know when they're ready. Stir at least once a day. If your hair won't slip, add wood ashes to make a weak lye solution. In this case, remember to rinse well before proceeding (see warnings about lye under "Soap Making"). Don't try to take the hair off until it comes off easily. You won't rot your hide by soaking it a little longer. When it's ready, you should be able to just rub the hair off with your hand.

2. When the hair is slipping, throw the skin over the beam that was described under "Rawhide" and commence working with your fleshing tool. Have the hide's neck up toward you, and work the flesh down the beam away from you.

3. You can use either the brains or soft-soap method for this stage, as follows:

   **Brains method:** Make a paste with warm water and the skull contents (the brain) of the animal. You can add any animal grease if you're afraid you won't have enough for the job, but generally each animal has
enough brain to treat its size of hide. The brain paste is applied warm to both sides of the hide. If you are worried that the brains won't keep while the hide is soaking, mix them with moss, make into patty shapes, and dry out by sun, fire, or oven. To get the paste on both sides, you'll need to lace the skin in a frame the same way you do with rawhide. Apply paste. Remove from frame, roll flesh side in, and store in a cool place for 2 days. Rinse well and wring as dry as possible. For detailed info, order the 52-minute video Brain Tanning Bison Robes the Native American Way by Larry Belitz (who is also a tipi expert: “Sioux Replications”). Or order his illustrated booklet, “Step-by-Step, Brain Tanning the Sioux Way”: HCR-52, Box 176, Hot Springs, SD 57747; 605-745-3902.

Soft-soap method: Soft soap is soap made with a weak lye solution. If you aren't a soap maker, shave up a bar of yellow laundry soap and dissolve it in water. Use 2 c. soft soap or 1 bar of laundry soap to about 2½ to 3 gal. hot water. Begin by rinsing your hide well. Then work it as it dries. Grease it with animal fat. Then put it into the warm soft-soap solution. Soak the skin in it for 4 or 5 days. Remove skin and rinse again. Work while drying again, according to direction in step 4 under “Rawhide.” The hide must now be continuously worked while it is drying. If you let the hide get dry in the middle of the job, it will get stiff and you'll have to dampen it again. Try not to get it too wet or you'll have to wait for the extra water to dry out. It can be pulled over the end of your beam or a stump and scraped with sharp stones or shells if you don't have metal tools. Or pull back and forth over a beam post with a wedge-shaped top. A small hide can be worked entirely by hand. A large one just about requires some kind of system, such as 2 people pulling it back and forth over a beam. The important thing is to somehow pull, twist, and stretch that hide in every possible direction to loosen the fibers of the grain. It is this procedure that makes the skin buckskin. You're done when the buckskin is almost as flexible as cloth. It should be easy to squeeze water right through the skin. If it isn't soft or you have hard spots, moisten and work while drying again until you are satisfied.

4. The final step is to smoke the buckskin. Before smoking, it's optional to go over the flesh side with sandpaper for any roughness. The smoking improves both the durability and appearance of the buckskin. There isn't any one absolutely fixed, correct way to do it. If you have a regular smokehouse, spread out the skin in there by stretching it horizontally. You can smoke several skins at once by arranging them in layers. Or you can fasten large hides together in a tent shape and build a small fire right under them. For the "tent," make a cone of small poles tied around the neck at the top, tipi style. Then arrange your hides over that. Burn green hardwood if you can get it. Don't use soft (pitchy) woods. Willow, birch, and alder are okay. The Indians used green willow, which makes the buckskin yellow. The smoking process will take 1 or 2 days. Don't scorch the skin. You'll have to turn it over and smoke the other side when the inside is done. The buckskin is finished when it is colored a deep yellow or light brown.
warm water and pin on a clothesline to dry. It might get stiff, so start when half-dry and rub to soften. Don't dry in a dryer.

**MAKING FUR THINGS:** You can lay a pattern on your fur, trace, and cut it out. You can sew together several small skins to make a robe, parka, vest, cap, or whatever you want. You can sew fur to the back of woolen mittens for extra warmth. Rugs and robes are probably the easiest things to make.

**Make a Fur Rug.** The easiest way is to just use a crude salt-tanned hide laid on the floor, wool side up. Such simple hides can also be used as lap robes, blankets, bed pads, truck and tractor seat covers, and so on. A more finished rug is made by cutting the skin to your preferred shape and trimming off the ragged edges. Draw around the skin to get your pattern, and then cut a piece of felt (or whatever material) about 1/2 inches larger than the skin all around. The edges of the felt are generally cut in a zigzag with pinking shears for attractiveness. For extra warmth you can put in a layer of quilting batt between the skin and the felt. Attach the felt to the skin by catch-stitching along the edges. Sew from the back. If you can, try to keep your stitches from going clear through the hide. If your rug has a tail with it, that is usually not bordered unless it is short.

**A Robe.** This is usually around 60 x 70 inches. One horsehide, one cowhide, 2 or 3 yearling cowhides, 8 calf hides, or 6 to 10 sheepskins or goatskins will give you a robe. You can use either sheared or unsheared sheepskins. You'll want to make sure that the fur or wool is clean and that tangles and burrs are brushed out. A robe can be unlined, but it is always nicer with a flannel or felt lining sewed on the way you make a fur rug.

**Fur Slippers.** Choose or cut out a piece of fur or sheepskin at least 4 inches longer than your foot and wide enough so that when you stand on the piece with 1 foot and fold the sides upward on each side of that foot, they reach at least 2 inches above your ankle protrusion. Now sew the backside of your slippers up where the backside of your heel will be. Cut to fit, and sew together the part that will go over the front of your foot. Hem down a 2-inch “collar” around your ankle, and run a leather thong or elastic through the opening to help hold your slippers on.

**Woven Fur Blanket.** You can make a blanket from many small skins, such as rabbit skins, by tanning them and cutting into strips about 2 inches wide. Sew together end to end until you have strips long enough to form the warp and woof of a basket-style woven blanket. Join the ends with the overhand baseball stitch and make sure that the fur is running the same way along each strip. The more strips you have, the bigger your blanket can be. When you have enough, fasten into place on a frame the strip that will form the warp. Interweave the woof, but not too tight. Put a piece of outing flannel on the back, and stitch together as if you were making a quilt.

**Other Fur Products.** You can make mittens, moccasins, shoes, and sheepskin coats. Leather-working manuals and other books can give you more patterns. There is probably a leather-crafts shop in your region where you can find guidance.

**Horns**

Horns are composed of a hard material that can be turned into a variety of useful and decorative objects. You can experiment and turn pieces of horn into buttons, beads, decorative inlays, knife handles, and even zipper pulls.

**FOOD FROM WATER**

As public oceans and rivers more and more double as toxic dumping grounds for every city or country that can get at them, regular commercial water creatures are ever riskier to eat. The so-called FDA seafood inspection program actually inspects only 1 lb. of fish for every 160,000 lb. we eat. And the FDA seal of approval is false security anyway because the FDA has toxic limits for only a dozen or so modern poisons—even though biochemists know there are hundreds that today's fish may carry. And as increasing numbers of the world's people chase fish, the supply grows ever shorter.

The answer is growing your own food from water—in water you know is pure, using food you know is safe to enter the food chain—or buying the equivalent. Growing food from water, or "aquaculture," has been part of family farming in many places around the world for centuries. But now small-scale fish farming is booming more than ever, and rightly so. You can grow more of this healthy, low-fat, heart-protecting protein in a smaller space than any other variety of animal on your homestead! Water farmers grow clams, mollusks, catfish, yellow perch, bluegills, bullheads, crayfish, bass, trout, carp, tilapia, mosquito fish, and others. They market them as human food, bait, or as stock for other people's food-growing or ornamental ponds or fishbowls. As always, it's best to start small and get experience before you invest heavily.

Almost anybody can do some water farming. You can raise catfish in just a barrel! If you have as much as 10 acres and a water supply, you have room for several fish culture ponds. Fish can be part of the natural ecosystem on your homestead, with meat-eating fish eating discarded innards and algae-eaters profiting from pig and poultry manure used to fertilize the pond. Or you can feed them commercial fish feed made from residues of the agricultural industry. Or both.

**HELP FOR SICK WATER CRITTERS**

Alabama Fish Farming Center; William Hemstreet, Fish Health Specialist; 334-624-4016; fax 334-624-4050; 529 Centreville St., Greensboro, AL 36744; whemstreet@acesag.auburn.edu.

Southeastern Coop. Fish Disease Lab; Dept. of Fish & Allied Aquacultures, Auburn U., Auburn, AL 36849; 334-844-4786.

UAPB Cooperative Extension Program; Larry W. Dorman, Extension Fisheries Specialist; 870-265-8053; fax 870-265-8060; 523 Hwy 65 & 82, Lake Village, AR 71653; ldorman@gw.uaex.edu.

**ONLINE INFO**

aquanic.org takes you to the Aquaculture Network Information Center (AquaNIC).
agebb.missouri.edu/mac leads to the Missouri Alternatives Center website.

**MAGAZINES:** Aquaculture Magazine serves "the international aquaculture industry" with 45 non-ad pages bi-monthly issue, an Annual Products Guide each summer, and the Buyers Guide and Industry Directory each December. Coverage includes all water-grown species: abalone, alligator, baitfish, bay scallop, blue crab, bowfin, carp, catfish, freshwater lobster, hybrid striped bass, mollusks, mullet, etc.
oyster, paddlefish, prawn, rainbow trout, salmon, shrimp, soft-shell crabs, striped bass, sturgeon, tilapia, trout, whitefish, and aquaculture science. It's $24/6 issues/yr: PO Box 2329, Asheville, NC 28802; 828-254-7334; fax 828-253-0677; comments@aquaculturemag.com; www.aquaculturemag.com. The website includes an online discussion forum, archives of back issues, calendar of events, and weekly updated news items.

Austasia Aquaculture magazine promotes aquaculture in the Australasian and Asian regions. It covers all aspects of this vast industry in that region, including regular columns by industry specialists. Their delightful website is at www.aquaculture.com/au/.

Northern Aquaculture is "The Voice of Cold Water Aquaculture in North America since 1985." It's a monthly magazine (Canadian-based): $30/yr. Subscribers also receive a free weekly e-mailed newsletter. The website has Buyers' Guide, Events Calendar, and Aquaculture Jobs sections, etc. at www.naquaculture.com.

University and Extension Help: Aquaculture, like the rest of modern agribusiness, is spurred on by university Ph.D.s and USDA researchers and specialists providing tech services to corporate and also independent food growers. It is a huge, profitable, and often very technical part of the food-producing industry. Subscribers to Aquaculture Magazine also get a yearly Buyer's Guide and Industry Directory (300 pp.). This is a great resource for anybody interested in aquaculture, beginner to expert. For example, it lists name, phone number, and often the e-mail address of all the Extension Agent aquaculture experts! There are one or more in every state, beginning with Jeff Alfred of the Alabama Fish Farming Center (529 Centreville St., Greensboro, AL 36744; 334-624-4016; fax 334-624-4050), and ending with Joe Hiller, U. of Wyoming (PO Box 3354, Laramie, WY 82071-3354; 307-766-5479; fax 307-766-6403; jhiller@uwyo.edu).

Want to learn this business? Study at the School of Fisheries at the University of Washington, the U. of Idaho, Louisiana State U., Auburn U., or Texas A&M at Corpus Christi (361-825-2676; www.sci.tamu.edu/pals/mari.html). All have outstanding aquaculture programs.

Since 1980, the U.S. government has heavily funded aquaculture research and development. There are five regional centers from which these funds and services are administered:

- Center for Tropical and Subtropical Aquaculture: The Oceanic Institute, 808-259-3168; fax 808-259-8395; 41-202 Kalanianaole Hwy., Waimanalo, HI 96795; library.kcc.hawaii.edu/CTSA.
- Northeast Regional Aquaculture Center: U. of Massachusetts Dartmouth; 508-999-8157; fax 508-999-8590; 285 Old Westport Rd., Research 201, N. Dartmouth, MA 02747-2300; www.umassd.edu/specialprograms/NRAC.
- Southern Regional Aquaculture Center: 662-686-3285; fax 662-686-3569; 127 Experiment Station Rd., PO Box 197, Stoneville, MS 38776; www.msstate.edu/dep/srac.
- Western Regional Aquaculture Center: 206-543-4290; fax 206-685-4674; School of Fisheries, U. of Washington, Box 357980, Seattle, WA 98195; www.fish.washington.edu/wrac.

Other books: Farming the Waters by Peter Limburg; The New Field Book of Freshwater Life by Elsie B. Klots; World Fish Farming: Cultivation and Economics by E. Evan Brown; Trout Farming Handbook by S. Dumond Sedgwick; Koi of the World: Japanese Colored Carp by Dr. Herbert Axelrod; Creative Fishing by Charles J. Farmer; Fish and Invertebrate Culture by S. Spotte; Home Aquaculture: A Guide to Backyard Fish Farming by S. D. Van Gorder and D. J. Strange.

Aquaculture can be done in the city too! Read The Integral Urban House, an account of a 2-story Berkeley house that the Farallones Institute turned into a center to demonstrate “urban-scale appropriate technology”—including a 2,000-gallon concrete pool in the backyard containing black bullhead catfish, bluegills, and Sacramento catfish, with the power for water filtration and recycling provided by a windmill-operated pump.

Mariculture

This word refers to harvesting food from beaches—from the “intertidal zone” where sometimes the land is covered by ocean water and sometimes it isn't. Lots of algae, shellfish, and sea vegetables grow there. If you don't have a pollution risk in your area, this area has tremendous food potential. See The Sea Vegetable Book by Judith Cooper Madlener for info on gathering and using sea vegetables, and try Sea Vegetable Recipes from the Oregon Coast by Evelyn McConnaughey (2 volumes!) for ways to use them. Seaweed

INTRODUCTION TO ANIMALS

623
in Agriculture and Horticulture, edited by B. and G. Rateaver, describes traditional seaweed use in Europe, how to make seaweed extracts, etc. Nori seaweed can be grown on nets suspended under a raft in shallow sea water. Its culture also can be combined with raft culture for shellfish and fish.

**RAFT CULTURE:** Raising shellfish using rafts and/or floating pens is big business now. The first raft culture was done by a shipwrecked Irish sailor. He suspended a net into the water between 2 poles to catch sea birds, left it there, and then found out that mussels had fastened themselves to it while it was under water at high tide. Now the Washington State Department of Natural Resources, which supervises many acres of tidelands, leases sites to individuals and provides aquaculture advice. The techniques for farming shellfish have been around for only the last few years. It's an exciting new field for small growers.

**SHELLFISH:** For growing shellfish, it's handy to live right on the edge of the ocean. Or you can lease a few acres of open water from the Department of Natural Resources and tether a raft over it.

**Red Tide.** Don't go out to gather shellfish without knowing about red tide and being sure that the critters are safe to eat. "Red tide" is an algae bloom that can occur from late spring to fall. It's toxic to humans, although shellfish thrive on it. Shellfish on a diet of red tide are no good for human eating until they've gotten it out of their systems. Any filter-feeding shellfish—oysters, mussels, etc.—can have this problem. *Harvest only when the government in your area says it's safe to or, if without expert advice, harvest only in winter.*

**Mussels.** You start out by buying mussel seed (there is a specialist in northern California who grows oyster, clam, and mussel seed under laboratory conditions). Seed for about 1 million mussels costs about $1,000 and can be contained in a coffee cup. After "planted," only about 10 percent survive predations of flatworms, starfish, and other dangers to baby mussels, but that still leaves 100,000—so many that thinning may be necessary. They're ready in a year and can be harvested from September to June. They'll keep well, even out of water, as long as a week if kept cold and damp. To cook, remove the byssus (silky filaments by which they attach themselves to rocks), scrub the shells clean and drop them, shells and all, into boiling water. Or steam. (Don't overcook.) Then make a chowder of mussel meat in tomato juice. Or combine chopped mussel meat with pasta. Kamilche Sea Farms is a commercial mussel-growing operation: 360-427-5774; fax 360-427-0610; SE 2741 Bloomfield Rd., Shelton, WA 98584-8640; Kamilchesf@aol.com.

**Oysters and Clams.** You harvest these with a shovel at night, by lantern light, at extra low tide. Best results in windy, cold, rainy weather. But worth it! Aside from the harvesting method, oysters and clams are similar to mussels. You could model your oyster farm on the Jolly Roger Oyster Co., which grows bottom-cultured oysters: 360-665-4111; PO Box 309, Ocean Park, WA 98640.

**Greenhouse / Hydroponics / Aquaculture Combo**

Water can be used in a greenhouse for supplemental heating and cooling. It's cheap and readily available, and it stores more heat in less space than any other commonly available heat-storage material. Greenhouse water can be recycled to raise edible fish or to do hydroponic gardening. *Fish Farming in Your Solar Greenhouse* by William Head and Jon Splane explains how to use greenhouse water as a heat-storage material for growing fish and how to use the leftover food and body wastes of fish to grow vegetables. Thus all you must buy or obtain is fish food (for tilapia and catfish), and your crop is both vegetables and mature fish. William Head also wrote *Gardening Under Cover,* from which I quote (pp. 100–103):

"In this system, fish supply the fertilizer for the plants in the form of uneaten food and nitrogen-rich waste byproducts, and the plants help to keep the water clean by absorbing nutrients from the fish water. Ideally, additional fertilizers are not needed and equipment costs may be minimized. We have had both success and failure, trying to make the concept work . . . [after failure] we redesigned the entire hydroponic system, incorporating a method called the Nutried Film Technique (NFT).

"NFT can grow crops on much lower nutrient levels than are required in other hydroponic systems. This is particularly important for hydroponic designs that use only the relatively low nutrient levels of an aquaculture system. A shallow stream of nutrient water is circulated through a dense mat of plant roots. The upper roots in the mat are exposed to moist air. This provides both abundant nutrients and oxygen to the roots . . .

"The aquaculture tank was stocked with 60 small channel catfish (*Ictalurus punctatus*) and 120 African perch (*Tilapia mossambica*) . . . The fish were fed twice daily with a commercial fish pellet (Purina trout chow). The plants were irrigated entirely with the aquaculture water. During a 7½-month testing period, 90 pounds of edible fish were harvested, and each of the 24 tomato plants had an average yield of 9 pounds of tomatoes. Tomato plants of the same variety that were raised in the greenhouse soil yielded about 7 pounds of fruit per plant . . . this design required less labor than crops growing in the soil beds, and we never had to worry about watering the plants. Water flowed freely along the pipes throughout the testing period."

For more information, see the sections on greenhouses and hydroponics in Chapter 2. The New Alchemy Institute has done particularly useful research in this area. In the above-quoted book, Head wrote (p. 103), "New Alchemy's best hydroponic trial has produced about 2.3 pounds of vegetables per pound of fish food, plus the edible fish."

**Pond Fish Farming**

Some raise them for fun and family food, some as a business. A pond can provide irrigation water for your garden and orchard and a place for the kids to catch frogs and turtles, swim in summer, and skate in winter. If you plant a pond's banks with nuts, fruits, and Christmas trees, you get an extra dividend. And you can have waterfowl enjoying the top of the water. There are more than 2,000,000 farm fish ponds around this country. Stephen Scott wrote me, "I have, just this past year, begun to raise fish in very small ponds. I feed them worms and frogs, which we have in abundance. The ponds are hand-dug affairs, 24 feet in diameter and about 5 feet deep. They are spring-fed, and the fish seem to be growing surprisingly fast."

On the other hand, Lane Morgan carps, "Farm fish may be fed subtherapeutic doses of antibiotics, like other live-
stock. Farm fish and hatchery fish are crowded and stressed, like 'factory farm' livestock, and they suffer health problems and may be medicated accordingly. Also, the farms cause pollution problems, not to mention that the escapees that breed with wild fish can mess up the intricately adapted genetic responses of the wild species. I guess fish farms have their place, but I'm not a big fan.

**Step-by-Step Pond Building**

1. **Assess Soil, Water, Topography, Etc...** For a good fish pond, you need a reliable supply of clean water and a situation where either it doesn’t flood or you can arrange drainage to compensate for flooding. Your soil must be capable of holding water on both the proposed pond bottom and the sides, or else you’ll have to line it with Bentonite or some such. You need enough spring flow, well water, or runoff to fill the pond in a year or less and to replace water lost from seepage and evaporation.

   The ideal water source is a well, because then you will have no unwanted fish, no flood problems, and no muddiness. Well water, however, is no guarantee against pesticide pollution. Your well flow should be fast enough to fill your pond in a week or so, to replace water lost through evaporation in hot weather, and to supply oxygenated water. A problem with springs is that they often fluctuate seasonally—check on that. If oxygen level is not adequate, you just aerate the water. Water source also affects water temperature, which affects the fish species you can grow. In summer temperate zones, a surface runoff water source means warm water. Water from a well or spring means “cold” water. If there are fish in the spring water, you just filter it to keep them out. Stream water needs to be filtered to keep out other fish too.

2. **Get Permits.** Check with the local branch of the USDA Soil Conservation Service. Your land must contain a site considered suitable for impounding water. On most sizable places, there are one or more sites that can pass muster. Your pond can be viewed as a water storage or even wetlands restoration. If you have a swampy area that’s growing cattails, you can use that. But first you need to get an appropriate permit or, more likely, permits.

3. **Plan Size.** Don’t be easily discouraged. You can raise channel catfish in a barrel! But bigger ponds are easier to manage and succeed with. A warm-water pond for bass and bluegill fun fishing needs be at least an acre in size. Trout ponds are recommended to be at least ½ acre, though I’ve seen a very good one that was smaller. But surface area is vital relative to depth because it helps oxygen, which fish need to breathe, get into the water. At the other extreme, 15 acres is considered to be the maximum desirable size.

4. **Plan Depth.** Shallow water is a problem because weeds grow in it. In ponds stocked with bass and bluegill, those weeds protect small fish from the bass. Shallow water also causes mosquito problems. A pond is easier to manage if it has no shallow water. Deepening and/or filling will eliminate those shallow edges. A minimum depth of 2 feet is good, but 3 feet is better. So your pond needs deep sides to discourage plant growth but a smooth bottom if you plan to harvest by seining. Water 10 feet deep—or more—will allow the fish population to stay comfortable in winter.

   Where the pond will be covered with ice for a month or more and winter fishkills are frequent, water depth may need to be as much as 20 feet. If your pond depends on seasonal rains for its water supply, water should be at least 10 or 12 feet deep over a fourth or more of the pond area. A shallow bottom is desirable for bluegill and bass to nest in. Throughout most of the South, an average depth of 3 to 4 feet is adequate for fish growth; no more fish can be grown by providing additional depth.

5. **Plan Spillway and Drainage.** The emergency spillway to prevent floodwater from going over the dam should be designed to keep the flow shallow. This prevents big fish from swimming out and unwanted fish from swimming in. To prevent unwanted fish from entering the pond from downstream, a 24- to 36-inch vertical overfall in the emergency spillway should also be used. A drainpipe is useful and is required by law in many states. It should be large enough to drain the pond in 5 to 10 days. An overflow pipe or trickle tube connected to the drainpipe keeps the normal water level a few inches below the spillway. This reduces erosion of the spillway and prevents excessive loss of fingerlings soon after the pond is first stocked. A device to take outflow from the bottom rather than the top helps warm the pond early in the spring, may save fertilizer, and may permit fertilizing in spring when the flow is heaviest. Plan your water cycle if the water will be aerated or filtered.

6. **Clear Trees/Brush.** Most trees and brush should be removed from the area to be covered with water. If possible, remove stumps and snags from the pond bottom. This leaves the bottom smooth for seining, which may be required for good management. Clearing trees and brush from a strip 20 to 30 feet around the pond reduces the amount of leaves that fall into the pond. Leaves discolor water and encourage growth of algae, and decaying leaves may cause oxygen depletion in the water. A cleared strip also provides a grassy bank for fishing.

7. **Dig/Fill.** A demolition expert could dynamite out some deep holes in it for you. Or if you have a meandering river on or beside your property that has left a former meander now abandoned, part of the meander might be blocked off for a waterfowl area for you. Or you can dig a pond from scratch with a bulldozer. There are many different ways to build a new water area or develop an existing one. A “raceway” is one nice way to raise trout; water flows downhill from one pondlet to another.

8. **Stock Pond with Fish.** Before stocking, eliminate all wild fish from your pond and drainage area to keep them...
from competing with the stocked fish for space, oxygen, and food. Draining the pond does it. Choose your fish species to stock based on the temperature of your water, its depth, what you have to feed, and what you want to eat. You can stock with a single species such as trout or with a combination of species, such as bass with bluegill. Private and certain state and federal hatcheries provide fish for stocking. You can get info on sources of fish for stocking from the Soil Conservation Service, Extension Service, Fish and Wildlife Service, and your state fish and wildlife agency. How many fish depends on the species you choose, your water, and whether you want to do supplementary feeding. Prices are reasonable; for example, tilapia fry (50 will fit in a teaspoon) are about 17 cents per 1,000, 14 cents per 5,000 [1992].

9. Do Long-Term Fish Pond Management. Intensive management with carefully figured and faithful fertilizing and supplemental feeding gives you the maximum harvests, but it can also be costly and time-consuming.

10. Breed Fish. This is an optional step. Hatching and raising fingerlings takes knowledge and attention. I'm not going that deep here, but if you want to learn how, the info is out there. You can even get a degree in fisheries management from the University of Washington!

A CHOICE OF FISH TO STOCK

Large-Mouth Bass and Bluegill. Every imaginable fish combination has been tried by fishery scientists. This is the one that works best. These are the species most commonly stocked in warm-water (80°F or more) ponds. Red-ear sunfish may be added for variety and to lessen the risk of the fish population getting unbalanced. The bluegill and red-ear sunfish provide food for the bass. The bluegills eat insects that eat pond plankton. The bass eat bluegills (and baby bass). With this combo, properly managed, you'll have good fishing for years. Alabama ponds that won't be supplemented are generally stocked with 50 bass and 500 bluegill per surface acre. With supplemental feeding you can stock with 100 to 150 bass and 1,000 to 1,500 bluegill per surface acre.

To keep your pond species in balance, the first year return all fish caught. The second year you can take out 80 lb. bluegill per acre, but still no bass. From the third year on, take 80 lb. bluegill per acre and 20 to 25 lb. bass per acre. When handling fish that will be returned, wet your hands to preserve the slimy protective coating of the fish.

Carp. These warm-water (80°F or above) fish don't need running water and are very good to eat. If the water gets too cold for their liking, they will hibernate at the bottom. Originally from China, carp has been a domesticated fish for millennia. There are several varieties. The grass carp is a vegetable. It prefers green grass and vegetables—all kinds of freshly cut land grasses, weeds if not too tough, leaves of some trees, all kinds of fresh vegetables, rice bran, and bean meal. The others are carnivorous but are not the biting, chewing sort; they suck in food from the pond bottom. The black carp needs a diet of snails. The silver carp eats plankton. You drop manure or night soil into a carp pond. The fish don't eat it, but other critics do, and then the carp eat them.

**BOILED CARP** Clean carp and cut into pieces. Sprinkle the pieces with lemon juice. Broil, turning once, for 25 minutes. Sprinkle salt on it and serve.

Catfish. Catfish are warm-water fish that prefer 80°F and above. They're good in more southern areas and do well in farm ponds. They grow well in water 70°F or more, slowly in 60-70° water, hardly at all in water colder than 60°F. They do well in a pond about 2½ feet deep at the shallow end and sloped to 4 or 6 feet at the outlet. You can stock with blue, channel, or white. Channel are easy to raise and easy to manage because they seldom reproduce in a farm pond. Catfish that do reproduce can result in pond over-population—more and more fish that are smaller and smaller in size. You can raise catfish in a combo. If your pond tends to become infested with unwanted fish, the answer is actually to also stock it with large-mouth bass and fathead minnows. The minnows feed the bass, which get big enough to eat up the undesirable fish; thus you get the maximum yield of catfish.

Once your pond is stocked with fingerlings, the fish come up at feeding time and compete for the feed you throw them. They can get to be 6-pounders. Harvest by regular fishing pole, seining, traps, or lift nets. Four to six feet deep is good for them.

Crayfish. These taste like lobster, are ready for harvest in less than a year, and will thrive in almost any pond, lake, stream, or swamp anywhere in the continental United States. They can live on hay supplemented with garden-cull roughage. There is a growing commercial market for them.

Although known as "crayfish," these are correctly called "crayfish." They are fresh-water crustaceans that resemble the lobster but are usually smaller. Little creeks around here have them. To catch them, you grab the crawdad in the middle with 2 fingers. Press the front pincers together and drop it into a bag. They're usually quite small, so it takes a lot—several dozen or so—to make a meal. For plain crawdad, just drop the live crawdad into boiling salted water and boil 5 minutes. Then serve. You pick off the shell and pick out the meat using toothpicks—sort of a poor man's lobster. For larger ones, pull out tail fin and intestinal vein. For tastier crawdad, add a chopped onion and chopped dill weed to the boiling salt water and serve with a garlic-seasoned melted-butter dip on the side. Crawdads are good served with biscuits.

Tilapia. Tilapia are very easy to raise. They can even survive in water without oxygen because they can come to the surface and gulp air. They are very disease-resistant and gain about 1½ lb. in 6 months if generously fed. Tilapia are algae feeders. The female holds her fertilized eggs in her
mouth and broods them there for 3 weeks until her fry hatch out. She doesn’t eat during that time. For about 3 weeks after hatching, the fry will hide in mum’s mouth when afraid, so during that time she still doesn’t eat much and loses weight. So tilapia raisers try to prevent spawning by hand-separating males from females. Tilapia taste good and sell well to pricey restaurants and grocery stores.

**Trout.** Rainbow and brook are the trout varieties usually stocked in ponds because they’re available, easy to manage, and easy to catch. You need a dependable supply of year-round good-quality water—from a well, spring, or stream. You need good water circulation—a minimum flow of 450 gallons per minute. You can stock either kind or both. If you’re stocking trout, don’t put in any other species of fish. Trout just aren’t able to compete successfully. This is a cold-water (70°F or less) fish. Stock a natural pond with no more than 500 half-pound trout per surface acre per year. With supplemental feeding you can stock 2,000 per year. With good management, your pond should reach its carrying capacity in pounds of fish within a year after stocking.

During the second year, trout don’t grow much unless the pond is fished enough to make room. Fishing is good for the crop! Each fish you take out lets the remaining ones gain weight faster. You can start fishing as soon as the trout are 6 to 8 inches long—about 6 to 10 months after stocking the pond with fingerlings. By early in the second year, they’ll be 12 to 14 inches long and weigh about 1 lb., and they’ll continue to gain weight. But only a small percentage of the trout you stock will live more than 2 years. At the end of 3 years, just a few large trout will remain, a number far below the carrying capacity of your pool. Time to start over.

**Cleaning Trout.** Keep the trout out of the water and away from the bank long enough to make sure it is dead. There are various ways to clean it. Start from the 2 fins behind the anal vent. Cut them off around the vent and cut forward to the neck. Then pull out and discard the internal organs and scrape out the bloody membrane tissue along the backbone with your fingernail. That tissue is the fish’s kidney. Rinse in water.

The head is handy if you want to carry the fish with you on a forked stick, with one branch through the gill flap and out the mouth, or if you have an almost-too-small-to-be-legal fish. If you want to take off the head, cut it right back of the gill flaps. There is no need to scale a trout. Put it on ice, if possible, while you’re waiting to either cook or freeze it.

**Wilderness Trout.** I once fried 3 small trout on a flat rock heated in my campfire. I had no salt, pepper, flour, or anything else to add, but I remember those trout from an isolated mountain lake as one of the best meals of my life. I was 16 years old. I had ridden 15 miles before that meal and had 15 miles yet to go. Makes for a good appetite!

**Quick Trout** Season inside and out with salt and pepper. Roll in flour or cornmeal until coated inside and out, or dip in beaten egg and crumbs. Fry in oil or lard. It will cook very quickly. Turn once. Watch to prevent burning.

**Dutch Oven Trout** Partly precook 5 slices of bacon in a frying pan. Preheat your Dutch oven and pour the bacon grease into the bottom of it. Put the trout in a layer to cover the bottom (about 4 medium-sized ones). Sprinkle with salt and pepper to taste. Lay the bacon over the trout. Put the lid on and cook in the oven at medium heat about 1 1/2 hours. Serve with lemon wedges, if you can get them.

**Planked Large Trout** A Victorian delight. Place fish whole on hot greased plank (hickory, oak, or ash—1 1/2 inches thick). Sprinkle with salt, pepper, and melted butter. Bake at 400°F an average of 15 minutes per pound for whole fish. When almost done, arrange a border of hot mashed potatoes around it. Brown under broiler. Surround with hot vegetables. Garnish. Serve on planks at the table.

**Eating Trout.** Peel the skin off the top side (it’s tasty too!). Very carefully, and in the best light you have, separate meat from bones—each person for himself. But do it for the smaller children, and don’t give any trout to toddlers lest you goof and get a tiny bone in it, on which they might choke. Peel the meat slowly and carefully from the side using your fingers for best results, or a fork if you’re squeamish. Peel from the head toward the tail and from above the backbone moving down, and cut along the ribs in order to avoid dislodging the fine rib bones from their connection with the backbone. If they do get loose with the meat, it’s a real nuisance trying to pick them out one by one, and it’s very easy to miss one. With practice, you can lift the whole side of flesh up off the little rib bones. Do the same to the other side of the fish, and you have your good eating ready.

**Other Fish.** Other cold-water (70°F or below) fish you might want to raise in your pond are muskellunge and northern pike. Another possible warm-water (80°F or above) fish choice is buffalo fish. There are other varieties, like the bluegill and redeye sunfish, that are stocked to feed not humans but fish that will then be human food.

**Fish Food:** As with feeding any other livestock, there’s a choice ranging from home-grown to ultracommercial feeds. Even among commercial feeds there are choices. You can choose feeds that have no preservatives, artificial colors, fixatives, synthetics, or pesticides.

**Fertilizer.** “Fertilizer” feeds the algae, which feeds the fish. You fertilize before the growing season for warm-water fish. In the extreme South, fertilizer can be applied year-round, but the fish-growing season decreases progressively toward the North, so fertilization is less effective in the northern states and may even do more harm than good. Too much fertilization can cause oxygen shortage and fishkills, especially if you also have an ice cover. Where fertilization works, ponds need refertilization any time during the growing season that a white object can be seen 18 inches or more below the water’s surface. (If the pond is fertile enough, the resulting algae bloom will obscure an object at that depth.) As many as 12 fertilizer applications per year can be of benefit to maintain that fertility. You fertilize with animal or people manure or other organic products.

**Supplemental Feeding.** In trout ponds, this can raise production from 100 lb. per acre to 1,000–2,000 lb. per acre. Feeds are sold as finely ground mash and as floating or sinking pellets. Or you can make home-grown feed by offering chopped meats, wheat, whey, greens, and earthworms; watch what they take and what they don’t, and be guided by that.

**Other Pond Management Tasks:** Keep an eye on what the waterweeds are doing. Maintain a balanced fish population if you’re keeping a combo. Be aware of the possibility of fish diseases. Maintain good water quality.
Preserving Food from Water

Use top-quality, fresh meat. Process for preservation as soon as possible after you catch (or buy) it. The longer you wait, the poorer the quality will be. To prevent spoilage, keep fish and shellfish cold—on ice or in your refrigerator. Handle raw seafood safely. Raw seafood may contain microorganisms that cause food poisoning. These bacteria are destroyed by heating the seafood before eating. Make sure that you wash your hands, utensils, and work surfaces (such as cutting boards) after handling raw seafood. Don't let raw seafood come into contact with cooked seafood.

Keep live shellfish (clams, oysters, mussels) moist and cold. Place them in a bowl, cover with a wet cloth, and store in the refrigerator. Keep fish on ice. Avoid rough handling. Don't stack fish on top of one another—this causes crushing and bruising, which speeds up spoilage. Keep live crab cool.

If you wish, you may skin the fillets. To do that, lay a fillet flat on your cutting board, skin side down. Hold the tail end with your fingers, and cut through the flesh to the skin. Flatten the knife on the skin and cut the flesh away from the skin by running the knife forward while holding the free end of the skin firmly between your fingers.

Preparing Catfish. Nail the fish through the head to some-

NOTE: Do not can smoked seafood; freeze it instead.
1. When you catch fish, remove viscera at once. Chill the cleaned fish until you're ready to can.
2. Before you can, remove head, tail, and fins.
3. Wash fish carefully, removing all blood.
4. Split fish lengthwise. Cut into lengths suitable for jars. (About 1 lb. of fish will fill one half-pint jar.)
5. Pack fish tightly into pint or half-pint jars, leaving 1-inch headspace. *Do not can fish or shellfish in quarts. You may add 1 t. salt per pint. You can also add lemon juice, vinegar, salt, or oil (1–3 T. vegetable oil or fresh-type dressing per pint) as you wish.
6. Adjust lids. Wipe jar rims clean with a wet paper towel before putting on the lid. Moisten towel with vinegar when you pack fatty fish such as tuna and salmon.
7. Process half-pints and pints for 100 minutes in a pressure canner at 10 lb. pressure (weighted gauge) or 11 lb. pressure (dial gauge). Increase pressure for higher elevations as shown in the "Altitude Adjustments for Pressure Canning" table in "Preserving Meat."
Eating Home-Canned Food from Water. Before tasting home-canned seafood, examine for spoilage. Bulging jar lids, spurting liquid, an "off" odor, or mold show that the food is not safe to eat. Do not taste or eat questionable food. For an extra margin of safety, heat any home-canned seafood before you eat it. Boiling the seafood, covered, for 10 minutes will destroy bot toxin. Or you can preserve texture by baking. To do that, remove lid and insert a meat thermometer upright into the center of the jar. The tip should be at the approximate center of the fish. Cover the jar loosely with foil and place in an oven preheated to 350°F. Remove the jar from the oven when the thermometer registers 185°F. You'll need about 30 to 35 minutes. Let the jar stand at room temperature for about 30 minutes. This will let the temperature become uniform throughout the jar. Serve the fish hot or refrigerate immediately for later use.

NOTE: If you prepare canned fish in a casserole, bake at 350°F and check the internal temperature at the end of the cooking time as described above for jar.

My favorite animal in my whole long life was the half-Shetland pony I rode as a child, Shorty Bill. I'll never forget the night that horse saved my life. Or was it my father who did?

Shorty Bill was half the size of a regular horse. I rode him every day to a country school 2 miles down the road, there and home again after school. One late fall day I took a notion to ride him from school directly over the mountain instead of going by the road. I let myself through the gate across from the little schoolhouse, and Shorty and I didn't have another fence from there to home. We were on what you might call open range. We slowly moved up out of Bracket Creek Canyon, where the school was, into the treeless top of the mountain that lay between the school and my home.

As I rode, dusk fell early. Then, without warning, out of the gray sky came a true blizzard. The snow began to fall thicker and thicker—big white flakes, and with them utter black darkness. The wind howled and whined in my ears, pushing against my pony's body and mine. I couldn't even see my pony's ears ahead of me. Though I was warmly dressed, as always, I started to feel a real chill on my face.

There was no light, no road, no fence to follow. No sound but the wind. I was a little girl of about 8 with no hope in the world but my pony. I knew those blizzards. I'd heard of sheared ewes and lambs had gotten caught in a blizzard. I'd heard of them for the first time. I was so frightened. What could I do? Who would help me? There was nobody.

Then I remembered my daddy once saying to me, soon after he gave me my horse, "If you ever get lost with Shorty Bill, just let him have his head." (That means let him choose and go where he wants.) "Horses have senses that people don't, and can't even understand. He'll take you home." I heard those words again in my mind just as clearly as if he were there with me, saying them for the first time. I was so grateful that Daddy had bothered to give me the bit of advice that now was the only hope I had. It had to be my answer. There was no other way. It had to be Shorty Bill who took me home. But was Daddy right? Could Shorty Bill find his way even in this storm? The storm wouldn't kill him even if he didn't find his way home. His body was so big and strong and warm. But it could kill me.

Nothing to do but trust and obey. Obey my father. In a sense, obey Shorty Bill. So I let him have his head: I simply let the reins hang slack instead of putting pressure on his mouth and neck to inform him which way I wanted him to go. Now he could go any way he wanted to. He would soon realize that.

Having given up the "steering," I instead concentrated all my efforts on keeping warm and hanging on. I made myself as small a target for the freezing wind as I could, hunching over my pony's back with my head low, my chin snuggled as deep into my coat as I could get, trying to shelter my face from the wind.

We went a very long time like that. Shorty wasn't one to hurry. He was old as horses go. He moved along steadily, though, and I felt soothed by his steady rocking motion, almost sleepy, except I had to make myself stay awake enough to hang on tight. I don't know how long it was, some hours . . .

Suddenly he stopped. That did scare me. As long as he was moving, I could still hope that he was taking me home. Now I peered up and out from my coat collar's shelter to a wonderful sight: I could just barely see the shine of light, right by the barn door. My daddy was there, standing out in the freezing cold, right under the light, right by the barn door. He must have been waiting for us. He walked quickly over and lifted me off Shorty Bill with one great swoop of his strong arms. He hugged me wordlessly to his chest for a long moment. Then he took Shorty Bill into the barn's wind-sheltered warmth, took off his saddle and bridle, and gave him an extra-big serving of oats for his dinner.

Whenever I remember that journey on Shorty's back, lost in the storm, I think about trust. Who you trust. How you trust when there is nothing else to do. And how that trust can bring you safely home. Whenever I think of that, I think that going home to Heaven must be like that. You trust because there is nothing else to do anyway. And your trust brings you safely home. I've felt that I was in darkness many times since that ride. But there's a hand that holds mine and an invisible light that goes before me. Guiding, guarding all the way. Though it be even the valley of the shadow of death.

HOW TO KILL, PICK, AND CLEAN A PIGEON ...............717
Cooking Pigeon
Although my mother could turn out good food on the old wood cookstove and wasn’t discouraged by all sorts of country problems, no part of the barnyard was ever really her thing except the chicken house. She loved her chickens and they seemed to love her. I love all the animals, including the big ones, but Mother was terrified of them. I remember one time Daddy had to be away overnight. Mother assured him that, just for once, she could manage to milk the cow. Well, I awoke the next morning to hear her hollering desperately outside the window. I ran to look, and there she was, perched on the very top of a fence post, balancing up there in some mysterious way while our gentle milk cow stood close by, patiently waiting to be taken on into the barn. Mother was convinced she was under attack.

I’ll never forget that scene because, although I’m lean like the Harshbarger side of the family (my full maiden name was Carlotta Louise Harshbarger; “Carla” is a nickname), Mother always packed quite a bit of weight, and her getting on top of that fence post was an achievement. If you don’t believe me, just go out and try to stand on top of a wooden fence post—no matter how much you weigh.

Every spring Mother had baby chickens living in a cardboard box on the kitchen floor, just like we’d done before we had plumbing.

Mother had a wonderful healing touch with sick animals. I saw her revive an almost-dead baby chick that had suffered some crisis of illness or injury. She would work the stiff little legs and wings up and down until circulation was restored. Then she’d wrap the chick in a soft white dishtowel (white from being boiled in lye water on top of the stove) and put it in a little box near the stove, wherever a wave of her experienced arm told her the brooding temperature was just right.

The chickens loved my mother. They got all her kitchen scraps. Daddy could feed the pigs on whatever else there was—the chickens had first rights. And they appreciated this. They laid eggs aplenty for us. If Mother went to town shopping and stayed away too long, the chickens would get restless and manage somehow to get the front door open. Mother would walk in and find chickens roosting all over—on the kitchen stove, the table, in cupboards. And they would all fly up and squawk at the sight of us, feathers and droppings going every which way.

I’ll never forget the taste of Mother’s fried chicken. First she’d have me go out and catch and kill a couple birds (she never could bring herself to come out of the house until that part was over). Then she’d appear with a big bucket of scalding water, and we’d pluck, clean, and cut up the birds together. That very night for supper we’d eat them. Mother turned up her nose at chicken that was over 12 hours from the hoof to the pan. She didn’t have a deep freeze. She canned lots of venison, but her chicken was always absolutely fresh.

CHICKENS
NOTE: The following section on chickens contains basic information relevant to all poultry varieties. In the other poultry sections that follow, only data that is different from the information in this section is covered.

Getting Started: Information and Supplies

POULTRY PERIODICALS: Most U.S. rural-living magazines have occasional articles on poultry—the most common homestead animal. And also . . .

Feather Fancier Newspaper is a Canadian newspaper focused on purebred poultry, pigeons, waterfowl, pheasants, etc.; $20 US/yr; sample $2; 519-542-6859; fax 519-542-4168; 5739 Telfer Rd., Sarnia, Ont. N7T 7H2, CANADA; featherfancier@ebtech.net; www.featherfancier.on.ca.

National Poultry News is “the Country Paper Country Folks Love to Read,” a homespun 32-pg quarterly, largely reader-written. It covers show birds, homestead flocks, and often other homestead animals and homestead topics too! Cost is $10/yr; sample issue $2 USA; $5 overseas. Contact Glenda L. Heywood, Editor: phone/fax 864-855-0140; PO Box 1647, Easley, SC.
1. Start your flock with quality chicks, bought from a local hatchery or mail-ordered, or incubate your own eggs.

2. Choose your best caretaking schedule: a small egg flock year-round, or a big meat-production for a few months a year (or both). Choose a broiler breed for your fryers, a good laying breed for your layers, or a quality meat–eggs breed and eventually raise your own.

3. Feed your cockerels or capons only long enough to get them to the eating size you want, butcher them yourself, and then can or freeze them, so that you won’t have to feed them any longer than necessary.

4. Use home-grown feeds when possible: pasture, household, and garden scraps; surplus milk; garden squash and mangels beets raised and cooked for your birds’ winter veggies . . .

5. Feed your birds a generous (and diversified) diet. To a real extent, the more they eat, the more they grow, and the more they lay. Make sure your birds have adequate ventilation, space, sunshine, and gravel for their gizzards.

6. Buy or raise some new pullet chicks every year; periodically cull your existing flock of layers carefully and send to the stew pot any birds that are performing poorly.

7. Shovel out the chicken house at least twice a year, age the manure in your compost heap, and then use it to enrich your garden soil.

8. Sell your surplus eggs direct to other householders at a reasonable profit to help pay for the cash expenses of poultry-keeping.

9. Preserving eggs evens out the spring surplus with the winter shortage and enables you to get along feeding fewer laying hens.

10. Keep basic records so you know where your greatest expenses and best profits are.

29641-1647, frizzlebird@yahoo.com; www.nationalpoultrynews.com; poultryconnection.com; www.g-exoticfarms.com.

New Zealand Poultry & Pigeon News Digest is a bimonthly journal sent air mail; 20 A4 pages on “interesting topics from constructive breeding to show reports.” Price $15 US/yr. Back issues and book list available: PO Box 133, Inglewood, NEW ZEALAND.

The Poultry Press is available monthly from 765-827-0932; PO Box 542, Connersville, IN 47331-0542. Cost is $21/yr; $59/3 yrs; sample copy $3.

Poultry Times: If agribusiness concepts don’t stick in your craw, to understand the commercial poultry production scene, and for good disease articles with solutions, spend $9 for a year’s subscription to Poultry Times; 770-536-2476; fax 770-532-4894; 345 Green St. NW, PO Box 1338, Gainesville, GA 30503; ptedit@mindspring.com or ptpub@mindspring.com. A commercial farm poultryman in your neighborhood would be a breeder (who sells eggs to hatcheries), a hatcherman (who sells just-hatched birds to growers), or a grower (who sells eggs and/or broilers to processors and distributors). But Poultry Times will ask further: whether you’re a broiler processor, egg packer and processor, hatcherman, broiler or layer producer, commercial egg producer, turkey producer, feed manufacturer, flock serviceman, batching egg producer (breeder), supplier to the poultry industry, turkey processor, started pullet raiser, ag college, veterinarian, government, financial advisor (banker), or nutritionist (poultry feed component specialist). Its calendar lists poultry specialty conventions, conferences, seminars, and short courses—all aimed at the for-profit, large-scale poultry operation.

Poultry Clubs, Museums, and Tours: The American Poultry Association offers membership, quarterly newsletters, and an annual yearbook and show awards for $10/yr. Contact Lorna Rhodes, Secty-Treas; 508-473-8769; 133 Millville St., Mendon, MA 01756; apanetcontact@home.com; www.ampltya.com. The Society for Preservation of Poultry Antiquities promotes endangered and rare poultry worldwide and also unites collectors of antique poultry equipment. Get a Membership Breeders Directory and four bulletins for $12.50/yr: Glenn Drowns, Sec.; 1878-230th St., Calamus, IA 52729. The Maine Alternative Poultry Association (MAPA) organizes growers with less than 2,000 laying hens or less than 10,000 meat birds: Dr. Opitz, 207-581-2771.

The National Poultry Museum at Bonner Springs, KS, is part of the National Agricultural Museum. It displays thousands of antiques representing the poultry industry’s heritage. Or visit the American Poultry Historical Society: Dr. Lou Arrington, Secretary, 260 Animal Sciences Bldg., 1675 Observatory Dr., Madison, WI 53706. Overseas, visit the Dutch Poultry Museum in Barneveld, Holland.

For the ultimate guided tour, join the 16-day annual Stromberg Poultry Fancier Tour. You’ll visit Sweden, Poland, Holland (International Flower Auction, poultry museum, and a private fancier), England, and Germany (the Thuringer Poultry Museum and the famous Hanover Poultry Show displaying 20,000+ birds of every type, plus dealers and suppliers), and more. For tour schedule, details, and price contact Loyl Stromberg: 218-543-4228; 8302 Big Whitefish Narrows, Pine River, MN 56474.

**POULTRY SUPPLIES:** For small flock service, look in your local Yellow Pages under “Feed Dealers” or “Poultry.” Your local feed salesperson can be an invaluable source of advice to help you get started and keep you going, as well as supply information on commercial feeds and basic components of build-it-yourself feed rations and general livestock supplies. Hatcheries, local or mail-order (listed below), often sell specialized books and poultry equipment for family flocks.
**Poultry Books:**

- **Raising Chickens** by Cynthia Haynes (1985) is fairly recent and carefully researched. **Raising Poultry the Modern Way** by Leonard S. Mercia (updated 1990) is a long-time classic for those who want a commercial operator's approach. If your interest is in a few chickens kept as pets or show stock in a suburban setting, **Bantams: A Complete Pet Owner's Manual** by Helga Fritzsche (1985), translated from its original German edition. Other useful books are **Chickens in Your Backyard** by Rick and Gail Luttmann; **Raising Poultry Successfully** by Will Graves (1985), which covers chickens, ducks and geese; **Starting Right with Poultry** by G.T Klein (1973); **The Complete Handbook of Poultry Keeping** by Stuart Banks (1979); **Raising Turkeys, Ducks, Geese, Pigeons and Guineas** by Cynthia Haynes (1987); **The Family Poultry Flock**, edited by Lee Schwarz (1981); **Raising Small Meat Animals: Efficient Home Production of Cornish Game Hens, Chicken Broilers, Turkey Roasters, Rabbits and Squabs** by Victor Michael Giammattei; and **Producing Eggs and Chickens with the Minimum of Purchased Feed** by Ed Robinson (1972).

**Chicken Breeds**

Here is a description of the different kinds of chickens, sorted out in various ways to help you make sense of it. To me, the most important aspects of a chicken are ranging, mothering ability, and climate suitability. But there's a bird for everybody's needs here. Browse until you find your perfect match. But first a useful definition: "sex links."

Sex links exist in various breeds and are always worth considering. Sex links are the offspring of the crossing (mating) of a "gold" (red, buff, brown . . . ) male with a "silver" (Wyandotte, Plymouth Rock, Sussex, Brahma) female. The chicks will be sex differentiated by color: males, cream or white; females, buff or red. The sex links generally belong to the "heavy" size category (see "Heavy Chickens" below). Keep in mind—if you are planning to incubate your own eggs—that they are hybrids, and crosses do not breed true. That means the chicks will not turn out like the parents. (Only pure breeds breed true.) The Black Sex Link is a meat-eggs hybrid gotten by mating a Rhode Island Red rooster to a Barred Plymouth Rock hen. The Red Sex Link has a Rhode Island father and a White Leghorn hen mother. Hatcheries like to see sex links because of the fact that good egg layers—or "heavy" eggs—that they are hybrids, and crosses do not breed true.

**GOOD EGG LAYERS:** The most efficient layers of all come from carefully selected genetic lines of chickens that have been developed for commercial egg production. The Leghorn is the old-timer in this field. White Leghorns are...
the best known, but Leghorns also come in brown, buff, red, and the black-patterned Columbian. Other modern breeds that lay as well as, or even a little better than, the Leghorn, are the New Hampshire, Golden Sex Link, Whelp-Line, and Barred Plymouth Rock. All these breeds, including the Leghorn, will lay between 245 and 255 eggs per year under good management. The best egg-laying breeds grow relatively slowly and eat a lot relative to the weight they put on. You can't have both top egg production and most efficient meat production from the same line of birds. It is also worth noting that at least 2 duck breeds, the Khaki-Campbell and the Indian Runner, lay eggs as dependably as these chickens.

**Egg Color:** Brown eggs are exactly the same inside as white ones. To find out what color egg a breed lays—if no one tells you and you care—just ask. In most places, brown eggs sell for 2–10 cents a dozen more than white eggs. In general, the smaller (Mediterranean-derived) breeds—Leghorns, Minorcas, Anconas—lay white-shelled eggs; the larger (American) breeds lay brown. The major English-developed breeds—Cornish, Orpington, and Sussex—are brown-egg layers, as are the Asiatic chickens—Brahma, Cochin, Langshan. Pure-bred Araucanas, chickens from South America, lay eggs in the purple to pink range. If an Araucana is mated with a brown-egg layer, half the offspring will lay eggs with dusky shells. If an Araucana is mated to a white-egg layer, half the offspring will lay eggs with light blue shells. An individual hen won't change color—no one tells you and you care—just ask. In most places, brown eggs sell for 2–10 cents a dozen more than white eggs.

**Size:** Chickens come in broiler, giant, heavy, light, and bantam weights. The concept helps sort out most of them, though many breeds now have both a large variety and a bantam variety.

**Broilers.** These are your basic meat birds. The ideal broiler is now expected to gain 4 lb. in 8 weeks and then go into the deep freeze. It used to be that meat birds were either extra roosters or culled hens. Then came a period when caponized cockerels were the popular meat birds. Now extra male chicks of egg-specialist breeds are frequently destroyed at the hatchery because, even at bargain-basement prices, they aren't the bargain that broiler chicks are if what you want is meat. Broilers grow phenomenally fast because they've been carefully selected from genetic lines that have maximum feed-to-flesh conversion ratios. That means with a broiler, 2 lb. of feed turn into 1 lb. of meat in just 3 weeks. The best laying breeds, on the other hand, would have to eat around 6 lb. of feed to gain a pound, and it would take longer than 3 weeks. Another way to put it is that your broiler will eat twice as much feed as the other breed, but you'll be done and putting it in your deep freeze 3 months sooner than you would the regular heavy breed. Probably the maximum farm efficiency is to have a good egg-laying dual-purpose (American) breed and raise some extra broiler chicks every year for the bulk of your meat birds. Don't let broilers grow older than 12 weeks because by then they've put on all their meat and mainly acquire fat.

Any “giant” or “Cornish” or “Cornish cross” or “jumbo” or “broiler” is a broiler. The hatchery catalog will make it clear to you which of their breed names means “broiler.” The Cornish-Rock is a hybrid of a Cornish rooster and a White Plymouth Rock hen. A friend who raised a batch told me they dressed out between 7 and 8 lb. at 12 weeks old. She said they made good roasters because of that sizable cavity to stuff and had huge breasts and lots of white meat. Hubbard Roasters are another rapid-growing, large-breasted bird. None of these breeds makes good layers because they eat so much more per egg they lay than a good layer does, and they don't lay as well.

**Giants.** Many sources rate Black Giants and Jersey White Giants as “heavy” chickens, but to me they fit best here, along with Cornish. Their capons may grow to 15 lb. The giants and Cornish are a little slower to mature than heavy breed birds or broilers. If you want to breed your own broilers, a purebred Cornish rooster mated to heavy-breed hens will produce acceptable meat-type offspring. Hatchery broilers come from carefully developed genetic lines that are protected, sometimes even patented. These birds do mate naturally, but only if they're on a lean diet, eating only about 70 percent of what they'd like to have. Cornish roosters do have a problem breeding because of their top heaviness. You have to pick your roosters carefully and not let them get too heavy. The small birds that you see in grocery store meat displays called “Cornish game hens” are Cornish Rocks that were butchered at 4 weeks of age. Butcher them at 2 lb. live weight to get the proper “Cornish game hen” dressed weight (1½ lb.). Pure Cornish are available from large fowl breeder Ken Herrig, President of the Cornish Club: KB4R@aol.com. Or from Billy Grimes, Secretary: bgrimes@fanninelectric.com.

**Heavy Chickens.** These also make good fryers and roasters and stay put behind a fence. Your extra roosters and over-age hens are meaty enough to make butchering worthwhile. They ordinarily eat more and lay slightly bigger eggs than lighter breeds. It is among the heavy chickens of “American” descent that you find your good combination meat-and-eggs barnyard breeds. They don’t grow as much meat as the giants, nor as fast, but their size is not shabby, and many of them are top-of-the-line egg-layers, too. Butcher these breeds at 16–20 weeks of age.

Rhode Island Reds, Production Reds, Plymouth Rocks, White Rocks, Barred Rock, Wyandottes, and New Hampshires fall into this category. Chicken breeds that were
developed in England and fit in this weight group are the Australorp, Dorking, Orpington, and Sussex. The Buff Australorp is an exceptionally gentle bird that is a good bet to set when the warm weather comes. The non-bantamized Asiatic chickens—Brahma, Cochin, and Langshan—belong here because of their characteristically large bodies; they also have feathered shanks and heavy bones, and they lay brown eggs. Hen weights range from 6½ lb. for a mature Wyandotte, Rhode Island Red, New Hampshire, or Black Australorp hen, to 7½ lb. for a mature Barred Plymouth Rock, White Plymouth Rock, or Black Minorca hen. (The Black Minorca is the largest member of the Mediterranean group of egg breeds, but by weight it belongs here.) The naked-necked Turken grows to be 6 lb. or more.

**Light Breeds.** These are the Leghorn and other Mediterranean-derived chickens, plus the Araucana—which is as lean as the Leghorn and still has all its brooding instincts—and the American-developed WhelpLine, a 5-lb. hen. The Houdan is an old-time French-developed light breed. California Gray, Sicilian Buttercups, Minorcas, White Faced Spanish, Blue Andalusians, and Anconas are other light breeds. The Sicilian Buttercups and Houdans are especially good layers. The lights are somewhat more nervous in temperament than the heavy breeds, which are better with children. The high-strung lights don't tame easily. A hen typically weighs 4-4½ lb. Leghorn roosters make passable fryers, though they are smaller than Reds or Rocks. Leghorns, or Leghorn varieties, are the general favorite of commercial egg operations. The white eggs sell better and color better at Easter. The smaller size means the chicken eats less per egg produced (though the eggs are slightly smaller). The production-oriented Leghorn gets a lot of bad press among homesteaders, but the fact remains that half a century of selection effort has gone into those birds to achieve ideal cost-efficient egg production. Lane Morgan, writer, gardener, and chicken-raiser, summed it up for me nicely: "Leghorns might be a good choice if you are raising a flock in confinement, on commercial food. I've had a Leghorn laying flock, and they certainly do lay, but I just didn't enjoy their company much. Incidentally, I find Araucanas much calmer and more sensible than Leghorns; I personally wouldn't lump them with other hysterical light breeds."

**Bantams.** A “bantam” is the bantam weight—a very small bird, smaller even than a Leghorn and about one-third to one-fourth the size of a large chicken. There are dozens of types and colors of them with wonderfully varying size, color, and plumage patterns, and they are popular as show birds for the county fair. There's a considerable size range among the different varieties. La Fleche is the heaviest with a 3-lb. cock. Silkies and Faverolles are a little over 2 lb. (cock); Chocin and Ancona cocks are a little over 1½ lb. The hen typically weighs slightly less. The black Silky was domesticated in China 4,000 years ago, the Chabos and Cochins 1,000 years ago. In addition to these ancient breeds, there are many new breeds of dwarfed commercials and other modern chickens, as well as ever-evolving new varieties of selections and crosses being developed for the hobby and show markets, mainly selected for their lovely or interesting feathers.

Bantams require less room and less feed than larger chickens. They provide less meat and their eggs are small, though actually large in proportion to the bird's body weight. (In a recipe, 3 bantam eggs equal 2 regular eggs.) Some breeds will lay almost as many eggs as a commercial chicken (La Fleche, 200/year; Amrock, 200/year; Ancona, 180-200/year), but most lay less than that; the Sebright and Game varieties rank at the bottom for egg-laying (50-80/year). These breeds are not the most efficient egg-layers, nor do they offer the most efficient feed-growth conversion ratios, but there is one important quality about some of them that merits consideration: many of these chicken varieties will readily brood and be good mothers. The majority of the modern bantam breeds, like the modern breeds from which they were dwarfed, do not reproduce naturally—they must be incubated. The traditional bantam hen, on the other hand, will virtually insist on becoming a mother, and is such fun to watch, and such a good mother, you'd probably be willing to allow it. To own such a bantam hen, choose a variety that has high ratings for broodiness, mothering, and foster-mothering ability: Ancona, Cochin, Silkies, Brahma, and Faverolle. Silkies and Cochins are also outstanding for their tranquil dispositions.

You can start out with just 2 bantams, male and female, and they'll do the rest. Or start out with just a bantam hen, and a regular-size rooster. Then, with genetic luck, her pullet offspring will have the mothering ability of a bantam and grow to more nearly the size of a large chicken. The older bantam breeds are also typically healthy (they can make it through almost anything) and cute, with lots of personality, and are great foragers, as well as good incubating machines for their or any other chicken's fertile eggs. A disadvantage to running bantams (which many folks call “banties”) together with a general flock, if you're hatching your own eggs, is that the bantam roosters are so wonderful at doing their thing that soon you'll have all half bantams—which is not good from the meat point of view. You can avoid that by eating the bantam roosters. Bantams are too small to be proper fryers, but they stew okay. A risk with these born foragers is that they'll become totally independent of you and roost in places you disapprove of, and you'll only be able to catch one with a .22.
You may want to join the American Bantam Association and get their quarterly newsletter: PO Box 127, Augusta, NJ 07822; 973-383-6944; fax 973-383-8633; fancybtms@Skylands.net; www.Bantamclub.com. They publish 19 books on bantams.

**CLIMATES:** If you live in the frozen North, the heavily feathered, heavy-breed Brahmas, Cochins, Orpingtons, Black Giants, and Wyandottes are worth considering because they are heartier and lay better in cold weather than more lightly feathered breeds. In general, the heavy breeds are the best for cold climates. Neither the broilers nor the light weights tolerate cold well. Frozen combs are a special hazard for cold-climate flocks. In unheated housing, large combs can tend to freeze, which causes lowered egg production from hens and a temporary end to the fertility of roosters in breeder flocks. So avoid buying such large-comb birds as the White Leghorn. A cold-climate bird is best adapted if it has a very close-fitting “rose” comb. The Mediterranean-derived breeds adapt well to warm or hot climates.

**BREEDS FOR RANGING:** In general, don’t buy any white birds if you have predator problems and expect your chickens to range free at least part of the time. They stand out too much. An alert, active variety handles predators better.

Regular size Anconas, Brown Leghorns, and Dark Cornish, and old-time bantam breeds are well spoken of in this regard. Araucanas, too.

**SETTERS AND NON-SETTERS:** Most chicken breeds have had the instinct to set and mother completely bred out of them, but some still have it. If your basic interest is egg production, broody hens are a nuisance. If you like the tradition of a natural chicken family you have to pick one of the breeds that can still handle that assignment. Breeds that will set are Orpingtons (Buff are best mothers), Turkens, Partridge Rocks, Buff Rocks, Speckled Sussex, Dark Cornish, Columbian Wyandottes, Buff Cochins, Partridge Cochins, and Light Brahmas, and any of the more lightly feathered breeds. In general, the heavy breeds are the best adapted to carry winter’s weight, and if you make sure they don’t run on ground that other birds have used within the past 3 years, there’s a good chance the new birds will stay healthy. If possible, bring your own chicks by incubator or mother hen.

**INTRODUCING NEWCOMERS TO AN ESTABLISHED FLOCK:**

4. The birds should be busily eating, dusting, or preening among the underarm feathers down by the skin. Feathers should be smooth and shiny.

3. Droppings should be well-formed rather than loose, and without the pinkish tinge of blood.

2. Combs and wattles should be shiny red (unless the hen is broody or mothering). Eyes should be alert and bright. Feathers should be smooth and shiny.

1. Look to see if they have skin or feather parasites. Do this by taking along a little magnifying glass and peer ing among the underarm feathers down by the skin.

**Pay attention to the first two points.** If you have no other chickens and the new ones are healthy, and if you give their housing a good lye-cleaning before they are moved into it, and if you make sure they don’t run on ground that other poultry have used within the past 3 years, there’s a good chance the new birds will stay healthy. It is possible, bring your new birds home near sundown. No matter what time of day you end up bringing them home, confine them in your chicken house until they’ve gone to roost there. Then keep them penned up for the next few days with plenty of food and water available. After a few nights of requiring them to roost where you want them to, their habit will be set and they’ll consider it home. Then you can open the outside door.

**YELLOW LEAF:**

1. 2. 3. 4. The birds should be busily eating, dusting, or preening generally active and curious. If they are quiet, with feathers fluffed out, they are not healthy.

**BRINGING NEW BIRDS HOME:** If you have no other chickens and the new ones are healthy, and if you give their housing a good lye-cleaning before they are moved into it, and if you make sure they don’t run on ground that other poultry have used within the past 3 years, there’s a good chance the new birds will stay healthy. It is possible, bring your new birds home near sundown. No matter what time of day you end up bringing them home, confine them in your chicken house until they’ve gone to roost there. Then keep them penned up for the next few days with plenty of food and water available. After a few nights of requiring them to roost where you want them to, their habit will be set and they’ll consider it home. Then you can open the outside door.

**INTRODUCING NEWCOMERS TO AN ESTABLISHED FLOCK:**

1. Look to see if they have skin or feather parasites. Do this by taking along a little magnifying glass and peering among the underarm feathers down by the skin. Feathers should be smooth and shiny.

2. Combs and wattles should be shiny red (unless the hen is broody or mothering). Eyes should be alert and bright. Feathers should be smooth and shiny.

3. Droppings should be well-formed rather than loose, and without the pinkish tinge of blood.

4. The birds should be busily eating, dusting, or preening generally active and curious. If they are quiet, with feathers fluffed out, they are not healthy.
Taming Birds: To tame new birds, get them to eat from your hand. And pet them on cheeks, head, and neck, and get them accustomed to being gently carried by you. But you may not want to tame birds whose life cycle will be strictly utilitarian.

Starting by Buying Chicks

The subject of raising chicks is so complex I scarcely know where to begin: With the chicken who lays and sets on and mothers her own? With the egg that you collect and incubate artificially and then raise the resulting chicks like a batch from the mail-order hatchery? Or with the chick that has just arrived in the mail and first of all needs the warmth of a brooder? I am guessing that most people nowadays get their chicks mail-order, so I'm starting with that. Afterwards, I'll tell you how to hatch your own in an incubator, and, last of all, how to let a mother hen do it the old-time way.

Mail-Order Chicks: These are incubator chicks that have been grown at commercial regional hatcheries and are sent through the regular mail to you if you’ve placed an order for them. It takes 21 days to hatch chicks, so you order and pay for them ahead of time. The earlier you get your order in, the better. Some hatcheries give price breaks for early ordering. Some get booked to capacity in the rush season and can’t accept more orders. Some rarer species get sold out way ahead of time. Hatches are scheduled for early in the week. You may want to order all your chicks at once—or to work with a smaller number at a time in a smaller brooder space and raise several batches—maybe one in February, one in April, and one in October. To start a large number of chicks and not have to worry so much about chilling in colder climates, the ideal time to get them is around July 15. At that time of year you could probably raise any number of chicks without even a heat lamp, if your nights are warm.

How Many? You should always have at least a pair of poultry—chickens, or any other domesticated birds—and a trio (a cock and 2 hens, preferably) is better; they really get lonely and don’t thrive without the companionship of another bird. But you’ll probably start with more than that if you start with chicks. Most hatcheries won’t ship fewer than 25 chicks at a time. That’s because it requires at least that many to create enough body heat to keep the chicks warm enough during their journey from the hatchery to you. Chickens get along best if they were raised together, so it would simplify your life to start your intended flock all together and at the same time.

Chicks for Laying Hens: An average hen will lay 220 eggs per year. A typical family needs 2 laying hens per family member to supply them with plentiful eggs. So you’ll order 25–50 chicks of a breed that lays well and has good food-egg production conversion efficiency. After the ninth edition of this book, Lane Morgan took me to task: “In these cholesterol-conscious days, that number seems high to me. We have done fine with one layer per person and have had enough extra eggs to supply a neighbor. With a 60-watt bulb on a timer, they lay all winter—not a lot but enough.” She’s right.

When placing your order, you’ll also have to choose whether you want to buy all pullets, “straight run,” or cockerels. Sometimes called “hatch run,” straight run means mixed-sex chicks. If you buy specifically one sex or the other, pullets of good egg-laying breeds may cost you from 2–8 times as much as cockerels. But, if your main interest is in eggs, they’ll be worth it. If you buy straight run, you’ve got to figure out for yourself when they get big enough what sex each is and treat them accordingly. (All, or most, of the cockerels would go into the meat count.) You’ll get about 50 percent of each sex. You’ll probably lose a few of the chicks you order to general hazards of the growing-up process. The remainder will become your flock of laying hens. So buy 50 straight-run chicks for every 20 laying hens you want. If you already have a flock of layers, the most economical practice is to replace around two-thirds of the poorest layers of them each year with new pullets. If you like keeping old friends around, though, there’s nothing in the rules to prevent you.

Pullet Chicks and Time of Year Hatched: If you buy pullet chicks in January, February, March, or April, they will mature while the days are still getting longer, and that will stimulate them to mature sexually and promptly commence laying. They will continue laying through winter and on to the end of the next summer. Or they may have a late molt that first year. Such pullet laying, though they’ll at first lay smaller and fewer eggs than more mature birds, can compensate for the molting time of older birds. Pullets that come into full production at a relatively young age do have a statistically greater tendency to prolapse (part of the tube comes out with the egg). But you’ll probably never encounter that in a small flock. Usually they will be fine and finish up their growth normally, together with their egg-laying. Pullets that mature after the days have stopped getting longer will not commence laying until the following spring. These late-laying pullets do lay more eggs, bigger ones, and more fertile eggs with less chance of poor health because they have come to full maturity before commencing laying. In that case, you would order chicks to come in July.

Chicks for Meat: How many days a year do you want to eat chicken? Once a week? Order 50 quick-growing birds to be raised and processed for the freezer as soon as they reach the target weight. Twice a week? Make that 100 of them. Or, if you’re not used to thinking of it by the bird or have a small family, 15 chickens per year per member of your family is a conservative estimate. Remember to include the cockerels from your laying stock (if you’re getting straight run) in your count. Lane Morgan again: “A 10–12-week-old Cornish cross is big. Our family of 4 gets at least 2 meals out of it, which affects menu planning and butchering quotas.”
If your interest is to get birds for roasting and frying, the broiler breeds are a shortcut to that end. Or try a straight run of a heavy breed. You may get offered a great bargain in cockerels (generally Leghorns). Don't jump at it unless you have lots of virtually free food to give them. It might be called something like “Super Bargains” or “Assorted Surplus.” It takes so many more pounds of feed to grow a Leghorn to eating size than it does a broiler breed that the money you save on Leghorn cockerels at the outset is more than offset by the extra feeding expense. Such light-breasted cockerels, if not bought by the uninformed, will end up in dog food or livestock food or ground up for fertilizer.

**Hatchery Sexing:** Sex-classified chicks are sorted at the hatchery by vent-sexing specialists who work with a lighted magnifying glass strapped to their heads. Accuracy is not absolute—only about 90–95 percent—which is really very good, considering how little they have to base a decision on.

**Of Debeaking and Dubbing:** The hatchery may offer to “debeak” and “dub” the birds for a small additional fee. I would decline, on the grounds that the expense to you and trauma to the bird is not necessary if you are going to raise them in a halfway humane manner. Nevertheless, here’s the data on debeaking and dubbing.

**Debeaking.** Debeaked birds have about half of the top beak cut off and the end tip of the lower one. At the hatchery this is done with an electrical device that cuts and cauterizes at the same time. You can debeak birds yourself with wire cutters, goat nail trimmers, pit-tooth nippers, or some such. The reason many big production operations have their chicks debeaked is because the natural end of a chick's top beak has a sharp down-curving extension with which they can peck other birds and with which they are said to fling some food out of the trough, causing waste. Objections to debeaking are that debeaked chicks are not as able to drink water and eat food, that they look mutilated and ugly, and that the beak is likely to grow out again anyway, requiring a repeat of the debeaking process. Most small holders, whose birds will not live with the extreme stress and crowding of huge commercial flocks, do not have their chicks debeaked.

**Dubbing.** “Dubbing” is cutting the bird’s comb off close to the head. If it is done to older birds, both comb and wattles will be dubbed, but with mature birds considerable bleeding is a problem. The argument is that this prevents frozen combs. Since frozen combs occur only in severe cold and inadequate housing, and in certain large combed breeds, it really is a rare problem. Furthermore, it is mainly the cock who is at risk from a frozen comb, because his comb stands up. Large-combed hens have a comb that folds over on itself and that helps keep it warm. Dubbing prevents the bird from naturally making enough Vitamin D from the sunlight to be independent of artificial rations—because they do that in their comb, their only unfeathered, unscaled part. Furthermore, if you don’t like a large comb, choose one of the many breeds with a small, close-to-the-head “rose” comb. You can do the dubbing yourself using an ordinary sharp scissors to decumb baby chicks. (Dub older birds using tin snips or commercial dubbing shears.) Better yet—to dubbing—just say, “No.”

**ARRIVAL AND INSPECTION:** The ordered birds, after hatching, are immediately shipped by whatever method will get them to the destination within 36–48 hours. Stay in touch with your postal carrier when you’re expecting. You may get a phone call from the post office with a background of melodic cheeping. Open your parcel at once in the presence of a postal employee. Count all the live birds. If there are dead birds or if the number you received is not equal to the number you paid for, have the problem verified by the postal employee in writing to the hatchery immediately. They’ll make good on it with replacement stock for you.

**Places to Buy or Order Poultry**

**Feed-Store Chicks:** At Kendrick, the feed store doesn’t sell chicks, but apparently in many other places it does. Lane Morgan said, “You don’t say much about buying chicks from the feed store, but that’s what I do. Find out what day their birds will arrive, and make your purchase several days later. That way someone else, probably with better equipment, has fed and sheltered the babies through those first touchy days. I’ve gotten 2-week-old birds for the same price as newborns, which saves a lot in food and hassle. This is a specially good deal for turkeys, since they are expensive and accident prone.”

**Mail-Order Sources, Midwest**

_Cynthia Dick_ sells roller pigeons, ringneck doves, call ducks, mandarins, four kinds of chickens, 12 bantam breeds, etc.: 1054 Fulton Rd., Hedgesville, WV 25427; tillys@barnyard@aol.com; www.tillys@barnyard.home.com.

_Inman Hatcheries_ sells goslings, ducklings, pheasants, turkeys, chickens: 800-843-1962; info 606-225-8122; PO Box 616, Aberdeen, SD 57402-0616.

_Eugene W. Leftelman_ offers chickens, peafowl, pheasants, ducks, geese, turkeys, rabbits, pigeons, and white-tailed deer: 815-857-3607 (call after 6 pm); 1785 Lee Center Rd., Amboy, IL 61310.

_Ridgway Hatchery_ sells meat-type broilers, white rocks, hamps, reds, barred, sex links, white leghorns, white pekin, rouen, mallard, khaki-campbell, Indian runner ducklings; emden, toulouse, and Chinese goslings; large white and bronze turkeys; ringneck pheasants; and guineas. Free catalog: orders 800-323-3825; info 740-499-2163; fax 740-499-2828; Box 306, LaRue, OH 43332-0306; www.ridgwayhatchery.com.

_Schlecht Farm & Hatchery_ offers 12 breeds of geese, 15 of ducks, and a large selection of rare breed chicks. Free brochure. Contact: 563-682-7865; 9749 500th Ave., Miles, IA 52064; Schlecht@netins.net.
Joe Schukar offers poultry, pheasants, doves, ducks—eggs, chicks, and adults in the fall: 308-468-6152; PO Box 507, Gibbon, NE 68840.

**MAIL-ORDER SOURCES, NORTH CENTRAL**

Bob Streich offers pheasants, wild waterfowl, peafowl, swans, chickens, emu, pheasants, geese, cochin, bantam silkies, etc.: 605-338-6797; 26704 481st Ave., Brandon, SD 57005-7203.

Stromberg Chicks and Gamebirds Unlimited sells chicks, bantams, ducklings, guineas, undercoats, turkeys, pheasants, quail, swans, peacocks, and "exhibition birds." Wide selection of rarer breeds. Full range of poultry equipment, books, Havahart traps, incubators: 800-720-1134; 218-587-2222; fax 218-587-4230; Box 400, Pine River, MN 56474; info@strombergschicks.com; strombergschicks.com.

**MAIL-ORDER SOURCES, NORTHWEST**

Clearview Stock Farm & Hatchery ships goslings, ducklings, bantams, chickens, turkeys, guineas, gamebirds: 717-365-3234; fax 717-365-3594; Box 399, Gratz, PA 17030.

John Marth Jr. offers pheasants, chukars, chickens (including Silkie bantams), jungle fowl, guineas, peacocks, doves, and pigeons: 570-676-0435; RR #1, Box 25B, Newfoundland, PA 18445.

Rainbow Feather Farm offers pheasants, doves, waterfowl, pigeons, and chickens. Send long SASE for complete breed list to Don and Rosanne Woodward: 717-734-3625 (evenings); RR 1, Box 339, Honey Grove, PA 17035; birds54@hotmail.com.

Cathy Smith offers pheasants, blue peafowl, chickens, and doves: 717-933-5438; 336 Long Rd., Myerstown, PA 17067; Cathsmith@Paonline.com.

**MAIL-ORDER SOURCES, SOUTH**

Double R Discount Supply offers 150+ breeds and varieties of chicks (poultry, waterfowl, gamebird), plus incubators. Free catalog: 321-768-1912; 4036 Held Rd. NW, Palm Bay, FL 32907; Sales@DblRSupply.com; www.DblRSupply.com.

Ideal Hatchery is the only place that offers capons. They also sell the commercial-type white Cornish roosters, etc.: 254-697-6677; fax 254-687-2393; PO Box 591, Cameron, TX 76520; chickenorders@ideal-poultry.com; www.ideal-poultry.com.

Larry Miller offers peafowl, turkeys, cochin, doves, quail, pheasants, etc.: 817-558-0606; 716 Many Oaks, Joshua, TX 76058; lmiller@cninternet.net.

Gerald Smith offers ducks, geese, turkeys, pigeons, standard chickens and bantams, etc.: 478-934-4286; Rt. 3, Box 2100, Cochran, GA 31014.

Unicorn Woods Hatchery ships chicks, chickens, bantams, cornish, cochin, turkeys, pheasants, ducks (eggs, meat, or exhibition breeds), Saipan jungle fowl, quail, peacocks, etc., by U.S. mail to any U.S. address: Carla J. Quataert; 870-895-4212; HCR 87, Box 832-N, Salem, WA 97256.

**MAIL-ORDER SOURCES, WEST**

Harder’s Hatchery sells “old favorite breeds” of baby chicks, turkeys, ducklings, guineas, bantams, and gamebirds. Free catalog: 509-659-1423; Ritsville, WA 99169.

Phinney Hatchery, whose motto is “cheepers by the dozen,” offers all sorts of standard chicken breeds, turkey poult, ducklings, guineas, and gamebirds. Free price list: 509-525-2602; 1331 Dell Ave., Walla Walla, WA 99362.

**MAIL-ORDER SOURCES, CANADA**

Frey’s Hatchery hatches eggs mid-March to mid-July: chickens, large white turkeys, broilers, crosses, Barred Plymouth Rock, Rhode Island Reds, ducks, pheasants, and ready-to-lay hens. Contact: 519-664-2291; 80 Northside Dr., St. Jacobs, Ontario NOB 2N0, CANADA; www.freyshatchery.com. No shipping to U.S.

**Brooding Chicks**

If you wait to order your young birds until local temperatures are quite stably warm—and if you have a draft-free place for the chicks—you can make do with a minimal source of heat their first week or so at night and that’s it. This is the closest thing you could have to a non-brooding option. If you’re going to raise chicks, you’ve got to learn at least a little about brooding them.

**INTRODUCTION TO BROODER STRUCTURES:** Newborn chicks are tiny, fragile, and fluffy. The basic characteristics of an adequate brooder setup for your chicks are warm, dry, draft-free, clean and cleanable, escape-proof, safe from predators, and expandable. But it doesn’t have to be expensive. Lane Morgan advised, “Distinguish between which is gradually moved down to make more room.

Although you have borrowed chicks, bought them, or home-incubated them, your first concern, once they appear in your life, is to supply a mother’s warmth. That’s what brooders are all about. If your chicks are to be brooded in a special room or small building, it should be tightly constructed, insulated, without drafts, and able to hold a uniform temperature. And yet there should be ventilation enough to move moisture and waste gases out without losing too much heat. If you choose a room (or build a room) in an outbuilding that doesn’t have electricity, you can use a heavy-duty extension cord to get power out there. If there is a risk of transmitting disease or parasites in your...
Your skin feels uncomfortably hot, lower the wattage or raise the box, and the chicks will run in and out of its warmth wattage bulb, like a 100-watt, because that could be too wattage bulb too close to flammable litter. Check on this by putting your hand about 2 inches above the brooder floor under the heat. If your skin feels uncomfortably hot, lower the wattage or raise the light or some such. Don’t completely cover a brooder. The heat will build up in there and can kill chicks or cause a fire. Overheated chicks will pant.

NOTE: Don’t start a fire! This may happen if you have the light bulb too close to flammable litter. Check on this by putting your hand about 2 inches above the brooder floor under the heat. If your skin feels uncomfortably hot, lower the wattage or raise the light or some such. Don’t completely cover a brooder. The heat will build up in there and can kill chicks or cause a fire. Overheated chicks will pant.

The Brooder House. A 250-watt infrared lamp, suspended about 18 inches above the floor level, will brood 75 chicks. Large brooder operations use a row of such bulbs with their individual hover areas. An advantage of using more than one bulb is that if one burns out, there is an alternative source of heat in the room. Inside this warm, draft-free building, arrange a little pen with sides made of whatever you want to rig up, and over it hang your heat light from the ceiling.

Chick Fencing. The chicks need boundaries to limit their area at first, help them find their food and water, and keep them from wandering very far from the source of heat. Naturally, you need chick fencing only if you’re brooding in an otherwise open area. If you’re brooding a small number of chicks in something like a box, it already has sides. Baby chicks can’t be put behind chicken wire; they’re so little they’ll walk right through it. You can buy a wire with finer mesh if you want to use that in your brooder design. You can’t use anything very low to fence them in. Baby chicks can fly over short obstacles by the time they’re a week old. One good system is to cut cardboard boxes into long sections at least a foot high, then tape or staple the sections together in a circular shape. Make it sturdy enough so it can’t possibly fall over. The circle is so the chicks won’t have a corner to crowd in, which could result in smothered chicks if you have more than a few in there. And it prevents drafts and keeps them close to the warmth, which should be focused at the center of the circle. Start out with the fencing 3–4 feet out from the heat source. Day by day, as they grow in size and endurance, you can keep adjusting their “fencing” outwards. After a few weeks, your chicks have outgrown the need for fencing and you can remove it and let them run all over their pen’s area.

Homemade Cardboard-Box Brooder. The typical homemade incubator involves a light with foil focuser, or heat lamp (or a box just the right distance from a heat source for the temperature you need if you have no electricity). If a bulb is used for heating, keep in mind that infrared is better than white-light because the birds are less likely to pick at each other under infrared. A cardboard box 30 inches square with high sides, situated in a room where the temperature doesn’t drop below 65°F, with a 69-watt light bulb shining from overhead could handle 50 chicks to start. Make sure you’re not using the type of bulb for indoor suntanning. Chicks can sunburn, too. And don’t use a high-wattage bulb, like a 100-watt, because that could be too hot, and bright light in a brooder can result in excessive picking. Such a heat-box arrangement is your brooder.

Covering a half to a third of the box top will also retain heat in the hover area. It’s ideal to have a 6- by 8-foot space for 100 brooder chicks to allow some growing room.

Adding a “Room.” You can add space for chicks who have started out in a cardboard box by cutting out one side of the box and taping on other boxes, as needed, to create additional “run” space, and to provide space in which to offer food and water. Where you cut away the side of the box, hang a piece of cloth. That helps keep heat in the hover box, and the chicks will run in and out of its warmth through the inch or two you leave between the bottom of the cloth partition and the bottom of the box, just as if they were running to and from the warmth of a hovering mother hen.

Commercial Brooders. You can purchase a ready-made brooder in the size that is practical for you. There is wonderful brooder equipment sold: infrared heat lamp brooders, or big commercial gas brooders and other non-electric styles. The most common and inexpensive style for small-scale brooding is an infrared light with a metal reflector to focus the light and prevent ceiling condensation from dripping on the bulb and exploding it, and a heavy guard wire under the bulb so that if the light fell the bulb wouldn’t touch litter and start a fire. Another common brooder-style is the hover-type brooder, which looks like a small flying saucer suspended from the brooder room ceiling on a chain. Larger brooders are equipped with thermostats to
control their heating. The principle of a brooder's operation is simple, and directions will come with your equipment.

**Wood Stove Brooding.** If you have no electricity or fossil fuels, you can still keep chicks warm. Put the chicks in a cardboard box. Put that cardboard box into a larger cardboard box that has a layer of hay, or some other similar insulating material along the bottom; insulate between the walls, too. Cover most of the top with a cloth or some other insulating layer (allow ventilation!). Put the box at a suitable distance from your source of heat. If that isn’t warm enough—and in cold weather, or on cold nights—fill a large jar full of very hot water. Wrap it in a towel to prevent burns, and place in the center of the box. Refill with hot water as needed. Check your baby chicks often, including several times a night, until they have outgrown that necessity.

**Solar Brooding.** The concentration of America’s poultry industry in Sun Belt states is partly because of chickens’ dependence on warmth, more so than any other livestock. Solar poultry brooding research has been done by the government, and solar brooding has been found to be technically feasible. For details, see *Raising Chickens* by Cynthia Haynes (see “Poultry Books”).

**Temperature Control:** Turn on the brooder the day before its occupants are to arrive and check to see if you can get the desired temperature.

**Checking the Brooder Temperature.** To control the temperature in any style of brooder, first you have to know what it is. Use a drugstore human-type oral thermometer or a brooder thermometer (mail-order from poultry suppliers for about $3). An oral thermometer is the most accurate sort. (Be sure and shake it down and wait long enough for the temperature to register fully.) Lay the thermometer just at the edge of the brooder’s heat circle. When using a light for warmth, you adjust to get the right temperature by raising or lowering the light until the temperature where the chicks are, around the edge of the heat circle, is 95°F (but not if you’re raising broiler chicks; see next paragraph). (Or you can put a smaller bulb into your light-heat socket.) An experienced brooder knows by a wave of the hand if the temperature is about right. The first week or two, while the chicks are at their most fragile, it wouldn’t hurt to get up 2 or 3 times a night and check on them.

Broiler chicks should start at 85°F. They don’t tolerate heat as well as other breeds—need less brooding and more ventilation.

**Chick Behavior and Estimating Temperature.** Chicks like, after they are one week old, is a very accurate indicator of temperature conditions in your brooder (before one week use a thermometer). If it isn’t warm enough, they’ll huddle directly under the heat source (or in a cold corner). Comfortable chicks make contented chirps. They may signal chilliness with a shrill peeping that says, “Mother, I need you!” If it’s too hot in the heat circle under the lamp, they avoid it. They may also spread their wings and pant. Under ideal conditions the chicks will form a circle around the edge of the brooder heat. They won’t be in the absolute center. If they are gathering at one side of the brooder, the problem may be a draft. Keep in mind that whenever a door opens, cold air may rush in at floor level—which is where the chicks are. And that draft can instantly and invisibly sweep away the accumulated heat from under the brooder.

### Decreasing the Heat

As the chicks grow older, they need less warmth. You decrease the heat 5 degrees a week by raising the heat source, say, 2 inches per week, until it gets down around 70°F. With an electronic brooder, you lower the temperature by changing the setting of the thermostat. Thus their second week you’ll have them at 90°F, their third at 85°F; their fourth at 80°F, their fifth at 75°F, and then their sixth at 70°F.

**Weaning Completely from the Heat.** After the 70°F point (they’ll be 6 weeks old), your brooder temperature depends to a large extent on your outside weather conditions. Probably you’ll start to turn their heat-source off during the day, but put it back on at night. At this stage, with warm weather outside, you won’t need the brooder any more at all, except perhaps if the nights are cool. Chicks come out of the egg with fuzz, then gradually grow feathers. In prolonged heat, they actually feather out a little more slowly. Their first feathers are a transitional set; they grow the “real” ones later. Exactly when you turn their heat completely off depends on what the weather conditions outside are and how completely your birds have feathered out—probably a few weeks after you began to turn the heat off in the daytime, it’s a judgment call. But I’m getting ahead of the story here. Let’s go back to what those baby chicks need.

**Chicks and Light:** For the first week it will help your chicks to be in a lighted area 24 hours a day. It’s during this period that they learn where the food, water, and warmth areas are. But make the night light only about 15 watts, since bright lights for brooding tend to create a pecking problem (they are also an inefficient and expensive heat source). Keeping chicks in a dimly lit place and using only small wattage green or red light bulbs in brooders will relieve a pecking problem. Chicks who have been raised under a brooder light, white or infrared, have to be gradually and gently introduced to true darkness when the time comes. They’ve been accustomed to associating light with warmth and safety, and they may be frightened when the light is gone and pile up and smother one another.

**Of Flooring, Chick Litter, and Spraddle Legs:** You don’t want the chicks to eat their own droppings. And you don’t want them to eat the litter. And you don’t want to slip on their flooring. In the first few days of a chick’s life, it is quite vulnerable to developing spraddle legs from slippery flooring. Long-legged varieties are most susceptible. Those early days their leg cartilage has not yet hardened and can easily be gotten out of position. Straw and flat newspaper are the slipperiest surfaces and the most likely to cause spraddle legs; their legs begin to turn sideways at the joint until finally they are turning straight out from each side. There is no cure for spraddle legs.

**Safe Flooring.** The shipping pads in the bottom of chick mail-order boxes are designed to prevent spraddle legs. For the first week or so you’ll want to come up with your own system. Thus, a good covering is clean burlap sacking. Put clean sacking down daily. Or clean rags. (If you wash these, don’t load them with bleach. The bleach could interact with material in the feces and result in poisonous gases.) If you are using a battery brooder with a wire bottom and the chicks are so small their legs are slipping through, cover the floor of it with your clean rags for the time being, changing it as needed for sanitation. If you use rags, make sure there are no loose threads that could get wound around a chick and kill or cripple it.
Newspaper Floor Covering. Later, once your chicks have definitely learned what is and isn't food, and their legs have grown strong, you may want to evolve to a thick layer of newspapers. This helps prevent them from eating feces since every day you roll up and take away as many layers of the paper as necessary to make their floor cleaning dry and clean. Don't use any colored pages as they are loaded with lead. Don't let the newspapers get wet and slippery. If you put a layer of shredded newspaper on top of the flat newspaper it will be more absorbent and will eliminate the slippery factor. Just tear the newspaper in strips, stir it up, and lay it down.

NOTE: Don't ever use newspapers as floor covering for ducklings, goslings, or turkey poult.

Loose Litter: Another option is loose litter, about 2 inches deep. It should be an organic, absorbent material—not straw, which is not absorbent. Don't use sawdust or sand as litter. Sometimes the birds will eat too much of it instead of their food and get an impacted crop and/or gizzard and starve. Sawdust also can become wet and moldy and cause disease. Hay or wood shavings, 2 or 3 inches deep, are good. The basic rule is to use litter pieces that are too big to fit into a chick's mouth—that way you're safe from them eating it—unless it's something utterly harmless, like potting soil, and that actually does work fine. If you use loose litter, turn it daily and remove wet areas. Small chicks are at risk from diarrhea organisms that thrive in wet litter. Large ones that cannot roost and must bed down in their litter (Cornish crosses) especially need it to be kept dry, clean, and fluffy to prevent them from developing dirty breast feathers and breast skin irritations. Once the chicks are 4 weeks old you can keep them safely on almost anything. Note: Some disinfectant and fragrance sprays will kill chicks.

Chick Dust. If your initial brooder arrangement is inside your home, soon you'll be wanting to move them elsewhere, for the sake of cleanliness and your health. Baby chicks create a powdery, disagreeable dust that gets everywhere in their environment and is difficult to live with and to keep up with. Small traces of bird protein exit with the droppings dry to a powder. Those droppings to keep up with. Small traces of bird protein exit with the droppings dry to a powder. Those droppings turn to dust, and becomes airborne, can put longtime handlers at higher risk for cancer and any lung disease. This is true of all birds, from parakeets and parrots on; in fact, this is their loss of the fine down they wore at hatching. Shed down, dried droppings, and chick feed all contribute to the chick dust. People who work with birds a lot are subject to hypersensitivity pneumonitis (an allergic reaction in the lungs), also and variously known as bird fancier's, pigeon breeder's, breeder's, or handler's lung disease. Bird flocks may cause disease for humans and other creatures who breathe it. Also, don't provide broilers with roosts because they say some birds scrape those big breasts on the roosts. They let them conserves space in their house at night.

Moving into the Chicken House. It's best to delay the chicks' joining of the regular flock until they're big enough that getting picked on won't be a risk to life and limb. Somewhere between 10 and 12 weeks after hatching, you can put them out with your other chickens, depending on their size, the weather, and how well insulated or warmed your chicken house is. Move pullets into the hen house before they begin to lay to prevent throwing them out of the mood, as any major change is likely to do that to chickens. Pullets that are moved after laying has commenced may stop laying and go into a molt. To move larger birds from one housing to another, do so at night, placing them on the roosts in their new quarters so they'll have slept there a night before they go out the door in the morning. That helps them know where home is. If they're still not sure the next night, shoo them in there again, and shut them in for the night. If they're reluctant to go in, let them get a little hungry, then feed them in there.

CHICK AGE AND APPEARANCE: When the chicks are 5 weeks old, you'll be able to distinguish the cockerels, who have grown pink combs and clearly visible wattles, from the pullets, who grow and color their decorations slightly later. The final adult
plumage starts to grow when the bird is 12 weeks old and will be finished coming in by 16 weeks. To make a pet out of your bird, this 12–16-week period is a good time to carry and pet it frequently. Be gentle, and the fowl will learn to trust you and be your friend.

**Chick Water**

**Waterer Types:** To make a homemade chick waterer, fill a quart jar with water. Put a shallow bowl upside down over the open mouth of it like a cover. The bowl's diameter should be only a little more than that of the jar top. Quickly turn the whole thing upside down outside the chick pen. The jar will slop for a moment. Slip a match or toothpick under one edge of the jar to keep the water flowing as the chicks need it. Set it down in the chick pen like that. There are also well-designed commercial waterers (and feeders) available mail-order from poultry specialists or from your local feed store. You need a minimum of two 1-gal. waterers per 100 chicks. By the time they're a month old, you’d find it convenient to be using a 5-gal. waterer per 100 chicks. Lane Morgan advised me, “You can buy a plastic base that works with a quart jar. If you use commercial plastic gallon waterers, I'd say get the kind with prongs and slots, not the kind where the top screws all the way onto the base. The screw kind never screws on right.”

**Chick Water Don'ts:**

1. Don't give water in containers with edges over an inch high.
2. Don't use a container deep enough that a chick could fall in and drown. (If they can, they will.)
3. Don't use a container that chicks could tilt or tip over by jumping up and perching on the edge.
4. Don't have an arrangement that allows any chick droppings to get into the water.
5. Don't give ice-cold water. (Serve it lukewarm, baby-bottle temperature.)
6. Don't let chick drinking water run out.
7. Don't put the water (or food) directly under the heat lamp.

**Chick Food**

If you have hatched your own chicks, rather than bought them, they won't be hungry right away and shouldn't be fed prematurely. Once you see them start pecking at their litter or flooring, it's time to feed them. (They should be watered before they are fed.) Have feed ready when you put mail-order chicks into their first brooder. And have their litter (if you are using organic litter) covered with newspapers, which are covered with cloth the first 4 days—until they've learned what's food. Mail-order chicks may have been hatched 3 days when they arrive and be ravenously hungry and start eating litter in their instinctive, but uninformed, search for nourishment—which at best would cause them indigestion and at worst, death. Young chicks instinctively peck at anything that is at the same level they're standing on. So, for the first few days or week, feed them on paper plates, pieces of cardboard, newspapers, or in the bottom
part of egg cases or small box tops to maximize access to proper feed and encourage them to learn how pleasant eating the right stuff is.

Once they learn to eat food, you can feed them in tuna-size cans or jar lids, or shift them to commercially made trough feeders or other suitable containers. Don’t place feeders right under the heat center. Instead, place them like spokes on a wheel, with their main portion out of the central heat area and waterers between them. Plan one inch of feeding space per chick. But by the time they’re a month old they’ll be needing 3 inches of feeding space per bird, so you’ll need double the amount of feeder length they required at the beginning. At any time, you want an arrangement they can get at, but not walk in. And one that won’t allow them to waste feed by scratching it out of the container. They also have a tendency to toss it out with their beaks. It will help in that regard if you don’t fill their troughs over half full. Research has shown that any poultry, given full-to-the-brim feeders, will waste about ⅙ of the contents! If their feeders are only ⅔ full, waste drops to about ⅙ of the contents. At ⅓ full, waste is down to more like ⅙. They should clean out one batch before you give them another, so stale feed won’t accumulate at the bottom of their feeder. The birds will be put off by the presence of stale feed and won’t eat as much, and it could end up causing them diarrhea. Keep feed before them virtually all the time, for at least the first 6 weeks and preferably longer. Check the food supply several times a day.

**Diet Options:** When feeding chicks you have 3 choices. You can use commercial feed all the way; feed commercial chick starter at the beginning, phasing into a home-devised diet; or use home-formulated feed all the way. Chickens also need pebbles (grit) to help their gizzards digest food. It’s not necessary at this time to feed grit with commercial mash; chickens of any age being fed an all-mash ration can make it without grit. If the feed includes some coarse material or is a home-devised diet, add a very little sand sprinkled over the top. Or you can buy a product called “chick grit.” You’ll have to increase the size of their grit as they get older. Warning: Consuming too much grit called “chick grit.” You’ll have to increase the size of their grit as they get older. Warning: Consuming too much grit will make it difficult for them to swallow. The pellets are too large for them, so crumbles are best. (You can feed pellets if you mash them.) Feed all they’ll eat. Most people have the best success using the commercial starter. Chicks will eat heartily and grow fast. You can continue feeding your chickens with commercial products, moving from the “chick starter,” when they are 5 or 6 weeks old, to “growing mash,” and from that to the “laying mash,” according to directions on the package or feed-store advice. When you move the chicks from one ration to another, take a week to do it, thus making the change gradually: 25 percent new feed at first, phasing into 50 percent and, finally, 75 percent. There is a particular formula of high-protein feed for the fast-growing broilers. Don’t feed laying mash too early to your pullets; feed it from about 5 months on.

**Starter-Feed Antibiotic.** The starter feed contains antibiotic. Chick starter feeds are available at 2 levels of antibiotic content: low and high. If you are able to get prepared chick feed that doesn’t have any antibiotic at all in it, it would be less expensive. That antibiotic and expense are 2 reasons why many chicken-owners wish to shift their birds to home-based feed quickly. You can shift any time. Lane Morgan uses antibiotic-laced feed only the first few days, then shifts. By then the chicks have more natural resistance to infection. The longer you use the medicated chick starter feed, the more you risk birds becoming antibiotic-dependent and unable to be healthy on their own. “Growing” and “finishing” commercial feeds do not ordinarily contain antibiotics. To be sure, read the feed bag label. Your bird should be off antibiotics for at least 5 days before slaughter, and preferably more.

**From Commercial Feed to a Home-Based Diet.** Anywhere from the chicks’ fourth day on, begin to offer fresh, finely chopped greens as part of their diet, along with finely cracked grain. Barley, wheat, and oats are good. The plain grain should be no more than 5 percent of the diet at first, but you can gradually increase it, and increase the size of the grain bits. Supply sand for grit, then shift to a larger size grit when they are about 8 weeks old. By this age also you can have them completely shifted to the diet described under “protein” in the chicken-food section that comes in a few pages.

**Home-Grown Diet All the Way.** A young chick eats only a thimbleful of food per day, and that small quantity must supply all its different and complex dietary requirements. Supply a menu made up of 2 parts finely ground wheat, corn (not too much corn), and oats, combined; one part protein—such as fish meal, meat meal, a daily small portion of canned cat food, chopped hard-boiled or scrambled eggs, clabbered milk, yogurt, cottage cheese, or worms, bugs, and grubs (a combination of these is best of all; from variety comes nutritional adequacy); and one part a variety of greens: alfalfa meal, alfalfa leaves, or fresh green stuff—comfrey, chard, clover, lettuce, dandelion, cress, chives, grass, spinach, weeds (finely chopped). Other good diet components for your chicks could be wheat germ, sunflower seeds, powdered seaweed, powdered milk, and linseed meal. Their diet should be about 20 percent protein. To collect worms and bugs for them, lay boards on the ground in your garden, or wherever the harvesting is best, at evening. In the morning pick them up and serve what’s alive and gathered underneath them to the chicks. Never mind how disgusting it looks to you. The chicks will love it.
Their necessary Vitamin A comes in the green stuff. They'll also need ground eggshells and/or oyster shell (unless there is another source of calcium in their diet), fine grit or sand for their gizzards, and a sprinkle of salt. They grow they'll need coarser grit, and can handle coarser grain. After their fourth week, they can eat their grain whole. If they aren't getting any sunshine from which to manufacture Vitamin D, they'll have to have cod-liver oil, or some other form of D. You might ask how this chick diet differs from that suggested for mature birds: it doesn't—except that chicks need proportionately a little more protein and calcium, and they need their grain broken up to start with. (A mother hen breaks it up for them.)

When your weather is warm and sunny, you can let them out to pasture on clean ground after the sun has dried all the dew off the grass—briefly, at first, longer as they get older. Small chicks tire easily and need to rest and get warmed again. Watch carefully as a mother hen would that they don't get chilled or become a meal to a bird of prey or a domestic cat. And perhaps provide a box on its side for shade and coziness.

But keep in mind that chickens, like any other critters, can get spoiled and picky as to what they will and won't eat.

**CHICK HEALTH PROBLEMS**

**Chick Diarrhea, or Coccidiosis.** This is a widespread problem for young poultry but is much less common in home flocks than in commercial ones. Coccidiosis is caused by a protozoan parasite that birds pick up from feces. There are many varieties of *Coccidia*, some of which make birds sick and some of which don't. Most varieties trouble only one type of bird and not the others. Symptoms of a serious attack are blood in the droppings and an obviously sick bird. To prevent it: avoid overcrowding, feed a balanced diet, keep food available. Commercial, medicated feeds contain medicine at a low level to permit the birds to develop immunity, or at a high level to control the disease completely. In the absence of such medication, manage your chicks in such a way as to minimize the possibility that they will eat litter or droppings. Refill water containers more than once a day, and sterilize the water containers once a week. Keep the litter dry; remove any portions that have gotten wet. Coccidiosis is more likely to strike in damp, chilly weather, so keep young birds dry and warm.

A home remedy for coccidiosis is to add 1 T. plain vinegar per quart drinking water for 3 days or until the chick droppings look normal again. (Don't give cod liver oil while giving vinegar.) Conspicuously sick or weak chicks that are being persecuted by stronger siblings should be separated into a special hospital-brooder box until they can get their strength back. Dead chicks should be removed from the pen immediately and burned or disposed of in a way that couldn't spread disease to the others.

**Pasted Vent.** This can be caused by chilling when the chicks are being shipped, although the pasted vent occurs a few days later. You'll notice a chick whose hind end is glopped up with droppings stuck to the vent area. It needs to be cleaned off gently. You can pick it off dry, but it is easier to hold the chick's hind end under lukewarm running water and gently massage loose the dried feces. The fluff around the vent will pull away too, which is a bit hard on the chick, but that can't be helped. After the cleaning, apply Vaseline to the area. Dry the chicks down with a hair-dryer or some such before you put it back with the others.

**Picking at Each Other.** Penny Anderson of Aitkin, MN, advises me: "If you have chicks picking at each other, cover the picked area thickly with Vaseline so when they pick they get a beak full of goo. Easiest to just put Vaseline on all the chicks' tails when the feathers are starting to come out. I've only had this trouble a couple of times. Haven't figured out why since they have always had a big pen, plenty of light, etc."

**Hatching Eggs in an Incubator**

The most productive modern chicken breeds (in terms of meat and eggs) are carefully selected genetic strains that won't go broody. So if you want more of them, you have to buy them again from the commercial hatchery—or incubate their eggs yourself. Home incubation is actually a practical option, especially with the inexpensive, but functional, small incubators available for sale. Even the smallest size, which will hold about a dozen eggs, can keep them adequately warm, humidified, and turning. Nevertheless, you're bound to have some eggs that don't hatch. Fifty percent is a poor hatch rate, 70 percent about average, and 85–90 percent is very good. If you have an incubator and can buy fertile eggs locally for reasonable prices, it's probably cheaper than mail-ordering.

**OF EGGS AND HEREDITY:** Look carefully to see whether one end of the egg is pointy or round. Pointy-ended eggs make roasters, says Ellinor Nurnberg of Ontario, Canada. Round-ended ones make hens. This method is 90% accurate. If you collect eggs from hybrids and crosses the offspring will not be like the parents. Raise pure-bred chickens of a kind you like. Then you know what you have, and you know what you're going to get. To raise crosses you'd have to do your own crossing by finding out what 2 kinds of chickens result in the cross you want, and then breed them. Whatever roosters, hens, and eggs you choose, choose the best: birds that conform to their established breed characteristics for fancy breeds, and birds that carry desirable traits of egg-laying, egg size, good health for egg–meat production breeds. If you're breeding from birds who are in their first laying season ever, wait to begin storing eggs for incubation until the hens have been laying several weeks. The first eggs tend to be smaller and less uniform in size, with lower fertility rates.

**GETTING HATCHABLE EGGS**

**Diet.** For prime hatchability of your eggs be sure to feed your breeding birds a diet high in protein with plenty of greens and comparatively little grain. The bird, if offered excessive grain, tends to fill up on it, like a kid with junk food, when what she really needs are the protein and greens. Laying mash is not a suitable feed for birds you want to hatch chicks from, but there is a special commercial feed for them called "breeder's ration." Free-running birds will do fine, or you can offer the home-based diet (see "Protein"). Both the roosters and hens involved also need to be fed regularly and generously since a rooster's reaction to loss of body weight from short rations can be sterility, and a hen's reaction is to quit laying for a long time. In general, the more eggs a hen is laying, the more likely her eggs are to be good hatchers, because she's in such prime health. The lighter the yolk, the less hatchable your eggs will tend to be.

**Rooster.** If you don't have a rooster among your chickens, none of the eggs will hatch; you need that daddy chicken
for fertile eggs. This is elementary birds-and-bees data, but I've met city folks who've never stopped to consider such details. Furthermore, the younger the rooster, the more likely his eggs will be fertile. (And the younger the hen, the more likely her eggs will be fertile.) A young light-breed rooster can fertilize a harem of 10–20 hens, while an old rooster can keep up with only 5–10 hens. A heavy-breed rooster, even a young one, shouldn't be assigned more than 8–12 hens. A bantam rooster is best matched with a harem of from 2–5 hens. Getting the right number of roosters for your hens takes delicate guesswork. Too many roosters causes the egg-fertility rate to go down, because then they spend more time fighting with each other than they do court­ing—or the egg production can go down because the hens are getting hassled too much. If there is only 1 hen per rooster, she can end up in really bad shape from too much mounting. And your hen must be compatible with your rooster, because some hens, to some roosters, will say “No.”

A rooster with a frozen comb won't be sexually active until his comb heals up, which can take several weeks. A molting rooster isn't interested either. Birds in batteries basically don't reproduce naturally, because of the low ceiling. You have to raise the roof, or artificially inseminate (see “Artificial Insemination” under “Turkeys”).

For a fertile egg the hen needs to have been inseminated no sooner than 24 hours before laying, and no later than 2 to 3 weeks. There is no way to look at an egg and know if that egg's mother has had a passionate embrace from a rooster in the required time frame. You'd just have to hope for the best and proceed. Once incubation has begun you can tell if the egg is fertile by candling it (see “Candling the Eggs”). But if you have actually seen the rooster mounting hens, you can start collecting eggs. A rooster has no penis. He breeds by simply pressing his vent to the hen's and extruding semen into it.

Daylight. No matter what the age of your rooster, he will be more fertile between March and May than he is during the other months of the year. More daylight causes his semen output to increase. Commercial egg-laying breeds may lay year-round; more natural breeds begin laying in February and will have fertilized eggs by March or April. That's because it takes the rooster longer to get going and become fertile than it does the hen. You can cause a rooster to get fertile earlier by extending his hours of light to 14 hours per day and warming him to 60°F. Five weeks after that change, approximately, he will get in the mood. It takes the hen 2 or 3 weeks after the days get long enough to have fertile eggs.

Handling and Labeling Eggs-in-Waiting. Gather them before night, if your nights are chilly, to keep them from possibly harmful low temperatures. Handle the eggs very gently and keep them either on their side or with the large end up—never with the small end up as that may cause the air cell located in the large end to rupture. Choose normal shaped, normal sized, uncracked ones. Don't wash eggs-in-waiting. The water could carry the very bacteria you're trying to avoid through the shell's pores and into the egg. If something on the egg shell is a real problem, buff it off gently. Yet very dirty eggs have been washed by desperate owners (less than 3 minutes in water 110–115°F), and the chicks lived to peep the tale. If you are incubating eggs from a variety of poultry breeds, it may help you to write on each egg—in pencil—a code designation for the breed. Write on the small end of the egg, because the large end gets broken away in the hatching process. You might write, for example, “M” for mallard and “L” for Leghorn. If you are keeping track of different genetic lines of the same breed you can give each pen a different number. In that case, you might have L1, L2, and L3, for eggs from 3 different pens of Leghorns.

Storing Eggs-in-Waiting. Placing the eggs in egg cartons works nicely, at a temperature of 49–60°F in a place that has at least reasonable humidity. That temperature won't kill the embryo, but it will keep it from commencing development. Don't store them in an air-conditioned room. Air-conditioning removes moisture, which is bad for the eggs. The temperature of your household refrigerator is probably lower than desirable and would reduce hatchability. Don't let the eggs that you plan to incubate go below 40°F, which will kill the embryo, or above 80°F, which would cause a slow growth of the embryo that weakens and eventually kills it. Actually, the embryo starts to develop at any temperature above 68°F, but the growth rate becomes a major risk above 80°F. Eggs that are going to be incubated should be turned or tipped 3 times a day. The easy way to accomplish that is by raising one end of the egg carton. Then, next time, raise the other end. Start incubating eggs from 1 to 14 days after laying, better in the first week than in the second.

Incubator Types: You can order incubating equipment to handle almost any number of eggs—from a dozen to 75,000. Most incubators are electric, but there are non-electric (kerosene, oil) models available. Each incubator comes supplied with detailed directions, and they'll work best if you follow those instructions very carefully. If you have a new incubator, set it up and level it. Run it a couple days to be certain it's working as it should. Test to see if it's keeping the temperature you want. Make sure the moisture pan has water. Before using an incubator that has been used before, clean it carefully. Or you can make a homemade incubator.

Homemade Incubator. The proper brooding temperature for almost all varieties of eggs is 99.75°F (which is just exactly the temperature under a mama hen). The most primitive homemade incubator is something like a bucket with eggs in it. The eggs are wrapped in a cloth and a light bulb is suspended over the top. This is the least likely to work, and yet I know of people who have hatched chicks with exactly such an arrangement. What you're striving toward is a heat source that can keep about a 2- or 3-square-foot area at approximately that 99.75°F. You can make a better box-style
incubator out of a Styrofoam cooler, or a cardboard or plywood box. If you make the top side of glass, you'll be able to watch the hatching. A plywood incubator with a 40-watt light bulb should be about 11 inches high, 11 inches wide, and 16 inches long, with a hinged front side for a door. With ¼-inch ventilation holes on each side—near the top of 2 sides, near the bottom of the other two—you get a natural air circulation inside your incubator. The eggs should be placed on the bottom of the incubator underneath the eggs. To test the temperature of the incubator lay a human oral thermometer among the eggs. It’s all quite adjustable: the wattage of your bulb, the material and size of the box—so long as you end up with the temperature you want in the place you want it.

**Commercial Incubators.** If you're buying an incubator, you must first choose between a still-air incubator and a circulated-air incubator. The still-air incubators are the smallest—with capacities of about 1,100 eggs—and least expensive. Still-air incubators depend on gravity to move air through vents on the top and bottom of the incubator. The operating temperature of a still-air incubator is always set a little higher than that of a forced-draft machine—101.5–102.75°F, depending on the variety of egg. (If you don't know the recommended temperature, go with 102°F, and you'll probably be fine.) You have to be home every day at certain times to turn the eggs. The cheapest, smallest models of all do not have a thermostat and are poorly insulated. Just as with incubating with a light bulb, this is not as cost-efficient or reliable as using more sophisticated equipment. The Hova Bator Incubators are well thought of for hatching small batches of eggs. Incubators that turn the eggs for you generally use either a mechanism that rolls the eggs or actually physically turns them. Avoid the “rollers” because eggs tend to get cracked.

Circulated or “forced” air incubators are used by large commercial hatcheries. They have fans that move air around the eggs. They cost more but give you better hatching percentages because of the improved control of the incubator environment and because the eggs are turned in a tray rather than rolled. With automatic egg-turning you are a lot freer to be away from home. Big models can hatch very large quantities of eggs. Humidaire incubators are expensive but give high-quality service. If you are planning to hatch very small eggs such as quail, ask your supplier for special advice on your incubator model.

**Humidity:** During incubation eggs lose some weight due to evaporation of the contents. The presence of humidity helps control that loss. Humidity helps your eggs to hatch. Too much humidity, however, results in a chick too large to hatch, or moving it near an alternative heat source. Circulated-air incubators are equipped with cooling systems. So if the heat system gets turned off for a while, don't panic. Maybe it was a day later in hatching. If the electricity should go off for a long time while you're incubating, try to keep the eggs warm anyway, by enclosing the incubator in a down sleeping bag, or moving it near an alternative heat source.

**Measuring Humidity.** Measuring incubator humidity is done with a wet-bulb thermometer. “Relative humidity” is determined by comparing the difference between the dry-bulb temperature reading and the wet-bulb reading. If the recommended relative humidity is 62 percent (correct for large turkey eggs during the first 25 days), then at a dry bulb reading of 99.5°F, the wet-bulb reading will be 87.5°F. If you have a hygrometer you can measure the humidity in your incubator air. You're aiming for a wet-bulb reading of 85–87°F the first 18 days of incubation (60 percent relative humidity), and 89–90°F the last 3 days (70 percent relative humidity).

**Increasing Humidity.** Incubator operators generally try to raise the humidity the last few days of the process. If the relative humidity wanted is 70 percent (correct for the last 3 days of turkey eggs) then the machine will be set at 99.5°F, and you'll be looking for a wet-bulb reading of about 90°F. Humidity in still-air incubators usually comes from an evaporation pan in the bottom of the machine. A soaked sponge sitting in the pan can increase humidity. If the weather is dry or the incubator is opened frequently you can supplement humidity by using a sprayer that emits a fine luke-warm water mist. Humidity is added by increasing the amount of evaporation area or by changing the ventilation; reducing the ventilation increases the humidity, and, in turn, increasing the ventilation decreases the humidity.

**Incubator Temperature:** The room in which you keep an incubator should be well-ventilated and at a temperature of around 60–70°F. Incubators (and brooders) are engineered to raise normal room temperature of about 70°F up to the required temperature, and they don't work properly in an unheated building and/or in cold weather. So don't let your incubator sit in the sunshine, or near a heater, near a window, or in a draft because any of those might be more than the heat control system can handle. Don't let the eggs ever get over 103°F. That would probably kill them.

A forced-air incubator should be set for 99.5°F; a still-air model is set for 102°F.

**Adjusting Temperature Setting:** Each variety of bird has a specific number of days needed to hatch its eggs. If your eggs hatch in fewer than that number of days, it suggests that the incubator temperature was set a little too high. Lower that setting 0.5–1°F and incubate another batch of that variety of egg. On the other hand, if your eggs took longer than the predicted number of days, then you should raise the incubator temperature the same amount. After several trial runs of this sort, you'll know the best temperature to set your incubator at in your particular environment.

**Cooling.** Most incubators are modeled on the original hen, and they cool the eggs 15 minutes a day—for 5 minutes at a time—which may or may not help. Circulated-air incubators are equipped with cooling systems. So if the heat system gets turned off for a while, don't panic. Maybe it was a day later in hatching. If the electricity should go off for a long time while you're incubating, try to keep the eggs warm anyway, by enclosing the incubator in a down sleeping bag, or moving it near an alternative heat source.

**Turning the Egg:** Faithful, frequent turning is essential to the embryo's proper development. A hen on the nest instinctively does that too. Not turning the egg regularly can result in a crippled or deformed chick, the death of the embryo, or a chick that can't hatch out properly (this is because turning prevents the embryo from sticking to the surrounding membrane, which can happen if it stays in one position too long).

1. Turn the egg from a fourth to halfway around at least 3 or 5 times a day. This helps the network of fine blood vessels through which an embryo breathes to finish developing. Some incubators automatically turn the eggs once an hour.
2. The odd number of turns will ensure that the eggs will be on opposite "sides" during the long nights, rather than always resting in the same position.
3. The way to tell where you're at is to mark an "X" on the egg and turn the mark up one time and down the next.
4. Any time you write on an egg, use a pencil, not a ballpoint pen or marker pen. Ink may be absorbed through the shell pores and may harm the embryo.
5. Be extremely careful not to cause shock or jarring to the egg when you turn it, especially in its first 24 hours, when certain delicate blood vessels are just forming. Some incubator operators skip that first day completely, not even opening the incubator door once, and start the turnings with day 2.
6. After the eighteenth day of incubation, quit turning the eggs. If you are hatching the eggs of a species other than chickens, quit turning 3 days before their expected hatching date.
7. From the tenth day on, make sure that the large end of the egg is at least somewhat up. Around the twelfth to fourteenth days, the chick takes a lengthwise position in the egg. If the small end of the egg is up at this stage, the chick will develop with its head in that end. With its head in the small end, a chick may manage to pip (peck a hole in) the shell, but it's practically impossible for it to hatch clear out. In a broody hen's nest, under natural circumstances, an egg lying flat will just naturally have the larger end a little more elevated. In the incubator you consciously have to make sure it's like that.

**Ventilation:** Whether you're using a homemade incubator or a commercial one, you need ventilation for it, because the developing baby chicks are taking in oxygen and breathing out carbon dioxide right through tiny holes in the shell. Without an adequate air supply, the embryo will suffocate.

**Candling the Eggs:** Candling, once done with a candle, is achieved by shining a powerful light through the egg in a dark room. Specific designs vary widely. You can use a slide projector, or a small box with a 40-watt light bulb enclosed in it, the insides covered with black paper, and just 1 opening, slightly smaller than egg-sized, through which you view the egg. You can buy a commercially designed candling box. Any method that enables you to thus examine an egg against a bright light in a dark room will work for white-shelled eggs; brown-shelled eggs take a longer time, but you can eventually identify an embryo in them too. The darker the egg's color, the harder it is to make out what is going on in there. To test eggs, hold each one up against the opening through which the light is coming, broad end upward (always!), and peer through it.

There is no way to know for sure that an egg is fertile without candling it. (Or opening it.) Some growers candle after 72 hours of incubation, when the fertile eggs have a typical blood vessel formation that looks like a spider. Some growers don't candle until 3 days before the scheduled hatch. (Eggs removed for being infertile at 72 hours or at 9 days can still be eaten.) Eggs in which the embryo has died and is now rotting must be removed because that process releases harmful gases and uses up incubator oxygen, and the spoiling egg may explode and scatter bacteria-loaded glop on normally developing eggs. If you're candling the eggs of a setting hen, do it while she's on her daily break. You may candle at any time you're concerned that the chick embryos might have been harmed by something. In such a case, wait several days after the trauma, to give the egg a chance to recover or perish, then candle.

**Candling Signs.** When you candle an egg, you will see one of the following: A clear egg means the egg is infertile or the embryo's development stopped very early. Remove it from incubator. A dark haze or grayish clouds mean the egg is rotting. (Note: At 2 weeks of incubation, fertile and normally developing eggs will be nearly dark throughout.) A dark red circle with no veins means the embryo has died. A fine network of veins radiating from a dark center means the embryo is developing normally.

If you candle a few days before hatching is expected, the fertile eggs will permit light only through the large end of the egg. The rest of it will appear dark or black in color.

**The Pipping:** Somewhere between the 19th and 22nd day of incubation, your egg will hatch—if it's going to. The chick has been getting food and water from the yolk, and oxygen from the air that comes in through the shell's pores. It took in calcium from the shell to help form its bones. The last thing the chick does before pipping (to "pip" is to make a hole in the shell) is to, over the last several days before hatching, draw the yolk into its body. The yolk goes in through its connection (like an umbilical connection) to the chick's lower abdomen. The drawn-in yolk makes the chick's abdomen bulge. The chick has to finish pulling the yolk sac into itself through its umbilical opening, and then grow that opening closed. At the same time, the chick swallows what is left of the egg's white. (That's why chicks can be sent by mail—that yolk can nourish them for as long as 72 hours after hatching.)

Starting as early as the eighteenth day, the baby chick may begin pecking at its shell from the inside. It pecks its way through to the egg's air space and takes a breath. Once the chick's head is in the air space you can hear it loudly peeping inside the shell. The ready-to-hatch chick has an "egg tooth," which is a sharp little extension on the end of its beak. (A few days after hatching, the egg tooth drops off.) On the 21st day, or thereabouts, depending on if the incubation was a little cooler or warmer than normal, the chick pecks a small hole in the shell. It has pipped. Incidentally, it's important that you leave the eggs completely alone during this pipping and hatching period; avoid even opening the incubator.
**The Hatching:** Making the hole to the egg's air space was hard work for the chick. It's tired now and goes to sleep for hours. When it awakens it goes back to work on the hole, pecking eagerly. As it pecks, it is gradually rotating its body inside the egg. The effect is that the crack it is creating gradually comes to extend in a straight line, which gets longer and longer until it is almost all the way around the egg. Then the chick gives a powerful kick with its big feet and it is out of the shell. It takes the chick from several hours to a day or two to get from pipped to clear out of the shell, and then a couple hours more, once it gets free, to finish drying off. When the chick is first out of the shell it is wet and tired. Don’t try to help it free or rush the process. If you peel the shell off for the chick, thinking to help, the chick will probably be worse off. It may still be in the process of drawing the last of the yolk into its body. (Note: Helping a chick out of the egg has been done, but it's a delicate business needing a knowledgeable person.) If a significant number of your chicks pip, but don't finish coming out of the egg, your humidity was too low. (Raise the humidity level the last 3 days before the hatching.)

The just-hatched chick rests on its stomach for a little while, and if you didn’t know better, you might think it was sick. When the chick first tries to walk, it can’t. It hobbles, using its wings to help. The chick gradually dries and gains strength. After they hatch, leave chicks in the incubator until they finish drying off and get fluffy (12–24 hours). They don’t need food yet, and it can actually harm them to be fed too soon. Baby chicks can scamper about as soon as they are rested and dried off from hatching. Then you can move them to your brooder. Clean the incubator thoroughly before storing it.

**Sexing Day-Old Chicks:** To get started at doing your own chick vent sexing you need a magnifying glass and the book called Sexing, compiled by Mr. Stromberg, published and sold by Stromberg Publishing Company, Pine River, MN 56474. It's very thorough, covers sexing many varieties of poultry, and includes diagrams and photos.

**Chickens That Hatch Their Own Eggs**

“Setting” or “brooding” are words that mark that dramatic turning point when a hen decides to start her family. Then she stops just laying her eggs and walking away, and instead she stays to sit on them, keep them warm, and so incubate out a family. It’s desirable or undesirable—depending on whether you want chicks or eggs. Or whether you want her to incubate or your machine to incubate. You can recognize a broody because her manner of speech changes from the everyday sing-song to a lower-pitched “come here” cluck that she will use to call her chicks. There’s no known way to force a hen to get broody. A dimly lit, private, comfy nest with several eggs in it may help incline her that way. When I was young, several of the hens in my mother’s flock would be broody at any one time. Five years ago you might get 5 hens that would go broody from a flock of 50 commercial-breed layers. Now scarcely one out of a 100 of them will try. And the one that does is likely to forget all about it after a few days on the nest, get up, walk away, and not return. If you want a hen to hatch out some eggs, you’d be best off choosing one from among the breeds that are known to still have genes for that behavior. (See the breed descriptions at the beginning of this chapter.)

A good reference on this subject is Bantams: A Complete Pet Owner’s Manual by Helga Fritzsche.

**The Brooding:** Just as soon as the weather starts to get nice, your broody-capable hen begins to want to set. A roaming chicken may make a nest in some secret place where she thinks it will be dry and safe and far from all the fleas and mites that may infest a chicken house. (Young birds are extra vulnerable to ectoparasites.) Or, in a hen house, she may choose the place where she is used to laying her eggs. She begins to lay eggs in the nest, an egg a day. Each day, before and after her laying, she sits a little longer on there. Under natural conditions a good setting hen will lay 10–14 eggs in her nest. There may be more than 1 hen laying in the same nest. Or you may not want every one of those eggs to be set. In that case, mark with a pencil the ones you’re going to let her set and take the rest. When she’s ready to incubate the eggs seriously, she may perfect her nest by picking feathers off her breast with her beak; these feathers will help insulate the nest. By exposing breast skin she is also able to share her body heat more efficiently with the eggs.

Once a hen has begun to set, you can, if she is in an absolutely unacceptable place, try to move her (carefully!) to a more suitable brooding nest that you have prepared. But brooding hens need to be undisturbed, and the move itself may cause her to give it up because of the disturbance. If you have more than 1 hen setting at a time, it helps if they are reasonably far from each other, perhaps in separate portable coops. But, again, it’s risky to move them. Another preparation might be to sprinkle the setting hen with a louse-repellent powder, once you separate her from the rest of them.

**Nest Design.** The brooding nest should be roomy enough that the hen can turn around in it and turn her eggs, and near enough to the ground that the chicks won’t take a disastrous fall overboard once they hatch—although they are very light and tend to survive such falls well. (After they are hatched you’ll take away the nest so that then the chicks can easily enter and leave their shelter together with their mother.) The typical human-designed egg-laying nest is not the best egg-brooding nest. Chicks are descended from ground-nesting species, rather than tree-nesting ones. An ideal nest is a little wooden house about 15 inches square and at least 16 inches deep, with the top roofed and the front side open. It sits directly on the ground. The ideal nesting material is grass turf. You can make a nest by laying the turf grass-side down, or grass-side up, or you can make a thicker nest by cutting 2 turfs of the right size, then placing their dirt sides together and placing them inside. In either case, pound down the center of the nest sufficiently to make it into a shallow saucer-shape so that the eggs won’t roll out. And moisten it with water.

**Eggs Per Hen.** A large hen that can cover and keep warm 14 regular-sized eggs will have to be given proportionately fewer if some of them are exceptionally large: 6–7 turkey eggs, 9–11 duck eggs, 4–5 goose eggs. Those numbers are not absolute but average: it all comes down to how large—and well-feathered—the bird is, and how large the eggs are. Insofar as possible, match egg size to bird. A small bantam hen finds a goose egg awkward to sit on; large birds are likely to break very small eggs (like quail). A bantam hen that isn’t heavily feathered may be able to cover only 8 eggs or so. Don’t give a hen more eggs than she can adequately
cover. If you do, you may lose the whole clutch, because she rotates eggs from the inside to the outside of the nest, so they all get chilled sooner or later. You can try the clutch on for size so to speak: give the eggs to her, and then look to see if she can cover them all. If you have goose eggs under a hen, you'll have to turn them 3 times a day yourself, because they are too big and heavy for a chicken to get properly turned.

**Eggs-in-Waiting.** Some chicken-owners, anxious to assist nature, collect the eggs and care for them as with incubator eggs-in-waiting until the hen actually commences setting. Since it's impossible to predict exactly what day she'll go broody, such eggs are marked with pencil stating the date collected. When the hen does commence setting, you supply her with a clutch selected from the eggs fresh enough to be the best bets for hatchability.

**Egg Adoption.** After a hen has begun to set, on one of the first few nights she stays on the nest, slip the eggs to be adopted under her late at night. It can be disastrous to put eggs under her after she's already been setting very many days because after 23 or more days of faithful egg-attendance, the hen may say "to-Hell-with-it" and leave the nest. On the other hand, many modern hens have such a weakened broody instinct that they are not dependable brooders and will soon give up and leave the eggs anyway. If you're worried your hen might not be dependable, let her set on fake eggs for a few days. Take her off the eggs a couple times. If she gets back on the nest each time, she's a good bet and deserves some real eggs to hatch. While she's setting, she will be very protective of her eggs and upset with you as soon as she realizes you're planning to do something under her. She'll peck at you with her hard little beak, and it can do damage. Wear a heavy shirt with long sleeves. You could wear a mitten, but I'd rather take a peck than take a chance with fumbling the eggs. Place them carefully under her, one by one, giving her a chance to receive and arrange to her satisfaction each individual one.

**Inter-Species Brooding and Mothering.** If you have commercial breeds as well as ones that will go broody, you can put their eggs under the broody hen. Setting hens of breeds that are good broodies and good mothers will hatch and try to mother even large eggs like those of ducks or geese, although they will get quite unhappy when those "chicks" jump into water and swim. If you want an egg to be adopted, follow the rules for eggs-in-waiting. Rare eggs that you're eager to try hatching can be kept for 4-5 weeks — until you have a broody hen that's just starting to set a clutch of eggs. The long wait will lower hatchability, but you might still get offspring. If there are eggs hatching at widely varying times, the hen may choose to follow an existing family and give up on the unhatched eggs. Any eggs left after the brooder gives up probably aren't going to hatch at all. A difficulty of inter-species egg adoption is that various eggs will have varying days to hatch. Pheasant, Bobwhite quail, and Chukar partridge eggs take 23-25 days to hatch. Guinea eggs take 26-28 days. Turkey, duck, and peafowl eggs take 28 days. Goose eggs take 29-31 days. Muscovy duck eggs take 33-35 days, and swan eggs take 35-37 days.

Human body warmth is just right to hatch eggs. Women of ample mammary endowment have incubated eggs kept between their breasts for the necessary number of days!

**The Brooding Routine.** Now your hen has her final clutch of eggs to brood. She sets on the nest for 3 weeks. On the first night she stays on the eggs, you can start counting toward 21. Many times a day she turns each egg in her nest very carefully halfway over and rotates eggs on the outside of the nest to the inside — which ensures equal sharing of the warmest and coolest locations in her nest by all the eggs. The broody hen is a willing martyr. She eats very little. She loses weight and her feathers get duller. She's very irritable toward visitors: she clucks, ruffles her feathers, even pecks at them. Now that she's seriously setting, she leaves her nest only once a day for food and water. She'll be gone only about 15 minutes, or maybe a half hour, if the weather is warm and the sun is shining so she doesn't worry as much about the eggs' chilling. Like a chick in the egg, a setting hen is receiving nourishment independently because, once she starts to set, she stops laying and instead begins to absorb the food energy stored in her conveyer belt of formerly developing eggs. Yet it's a friendly, helpful act to also leave fresh food and clean water close by for her. Her feeding excursion is a good time for you to peek and see what her nest looks like. But don't handle her eggs or nest while she's gone. Too much of a foreign scent around could cause her to leave that nest and refuse to return to it again.

She talks to her chicks while they're still in the egg and has a good sense of what's going on with them in there. If something like a severe thunderstorm or a prolonged chilling kills all the chicks in their eggs, the hen will know it. Be careful you don't accidentally shut a setting hen away from her eggs. She'll be frantic, and with good reason. Nevertheless, eggs that have been uncovered a night are not necessarily dead, though it may set the hatching back a day. The last 24 hours before hatching, she won't leave her nest even for the usual food and water recess.

**Humidity Assistance.** You can help keep the humidity right by keeping the earth between the turfs damp. If the weather is seriously dry, you can also help the hen by adding humidity. Some growers do that by spraying her eggs with a light mist of lukewarm water once a day, while she is on her break, starting on the 16th day. Other growers believe that spraying water on incubating chicken eggs promotes fungal growth and embryonic death and suggest instead flotation of the eggs — on the 19th day of incubation — in water that is exactly 97°F and for only 1 minute. But in real life it doesn't have to be that exact. Certain other species require even more humidity and even stronger measures. (See "The Waterfowl: Ducks and Geese.")

**The Mothering Taking in the First-Hatched Chicks.** A newly hatched chick is wet and could be fatally chilled if the mother isn't...
sitting on it to dry it and keep it warm. Some folks feel it's best to take the first-hatched chicks into the house—once they're safely separated from the egg and dried off. That's to save the hen the conflict of wondering if she should sit on the remaining eggs or follow lively chicks that have jumped out of the nest and are out in the cold peeping mournfully and maybe dying of chill. For just a few chicks that soon will be returned to the mother, keep them in a warm, dark place in the house—maybe in a box lined with newspaper and partly covered with warm cloth. Put the box where the brooding temperature is right, near a heater or under a light. Give them food and water using the general directions for chick care. It can also be a favor to the hen to pull out from under her the abandoned shells of fully hatched chicks.

**Returning Chicks or Adoption.** Return your borrowed chicks, if possible, the first night after the hatching is finished and the hen has been moving about with her chicks. This is also the time to give her any chicks you want adopted. A hen can mother more chicks than she can hatch. She can mother as many as she can hover over and cover when they need warmth. She doesn't literally sit on top of them; instead she stands and covers them—a blanket of warm feathers fluffed out all around them—plus dispenses the heat coming directly off the bare spots on her breast where she pulled out her feathers. Hens have been known to bring up as many as 25 chicks. So, if you have access to orphan chicks, or your own incubator chicks, or mail-order chicks, and if the timing is right, you can add them to the hen's family at this stage. The important thing is that your chicks, to be successfully adopted, have to be the same age as the hen's own chicks—preferably just 1 or 2 days old. Older chicks won't be as likely to obey the hen, and the hen will be more likely to reject them.

**Putting Chicks Under a Hen.** To accomplish the return or adoption of chicks is just like adding eggs-in-waiting to a hen's clutch. You wait until late at night, then slip each chick under her. The chick will be attracted to her warmth and will nestle under her. She'll fluff up more as needed and cuddle the new ones together with her others. To give chicks to a hen who has been allowed to set on fake eggs, put the chicks under her as above, taking away a dummy egg after each chick has been placed under her. You can't get a chicken to adopt chicks unless first she has become broody and set for 3 weeks or so. That's when she gets her mothering instinct activated. She might kill chicks given to her prematurely. These things have to unfold naturally, and there's a time for this and a time for that.

**Chick Rejection and Obedience.** Check the next day to see if she's rejected a chick. She does that by pecking at it whenever it comes near. It will soon give up and go hide its head because she won't peck at it if its bright eyes aren't showing. You can try to put the outcast chick under another hen, or raise it yourself in the house. You can't change chicks from one hen to another if their original mother is nearby in the same poultry flock. The chicks will remember the sound of their own mother's voice and always want to go back to her. And if you did inter-species brooding, you can't count on the young of very different species—guineas, wild ducks, peafowl—to follow and obey a hen mother. You have to watch and see if the babies are successfully bonding to the adoptive parent. If not, you'll have to mother them yourself.

---

**Chicken Mothering, Food/Water.** Hens, especially ones who are descended from a line of mothers who hatched and mothered their own chicks, can be very wise mothers. After only a few hours, the chicks know their mother. She teaches her chicks to come when called and to eat and drink. (Make food and water available. If it seems like it's taking time for the chicks to get started, remember they are equipped at hatching for 3 days in a desert. But if she's an inexperienced or inadequate mother, you can help by showing the chicks how to nourish themselves, same as for brooder chicks.) An experienced mother cracks seeds that are too large for the chicks in her beak and feeds them the small pieces. She teaches them what is and isn't good to eat. She'll find a bug, put it down where she wants them to gather, call the chicks, and tell them if it is or isn't good food.

**Chicken Mothering, Protection.** She watches carefully to see if the chicks are getting chilled and need to be called under her for a warming up, and to make sure she hasn't lost track of one. She can be fearless in defense of her babies. She can be dangerous to pet rabbits or guinea pigs that might happen to be in the area. An angry bantam fluffs out her feathers to the max to make herself look much bigger than she really is. She'll stand her ground against a far larger animal, making little pecking charges to try to drive it off. Unfortunately, a mother hen's blindly aggressive behavior may also extend to other mother hens—in which case chicks sometimes get trampled in the conflict, or may even be pecked by the other mother. (That's why it's wise to establish such families on opposite sides of your barnyard, or in separate coops.) She teaches her babies to be careful when cats come around and to look out for hawks.

**Separation from Mother.** A lost, scared chick sounds the alarm with a very distinctive, loud, "Peep, peep, peep." That's their S.O.S., and whoever is mother—you or the hen—better hurry and see what the problem is. A common serious problem occurs when 1 chick gets trapped somehow away from the group. The hen is torn; she doesn't want to leave the rest of her chicks unprotected, unwarmed, and alone, yet she doesn't want to abandon the separated one. In a case like that, you should interfere. It's generally as simple as lifting the isolated chick over some kind of barrier.
**Housing for a Hen and Chicks:** Keep the chicks away from the chicken house to start with, both to protect them from vermin and to prevent them from being pecked by larger birds, who can be very cruel. Or a predator, such as a roaming cat, might get a chick. You have 3 choices for housing: leave them alone to tough it out and hope for the best, start them in a big cardboard box or A-frame and then gradually set them free, or start them in a chicken coop or subdivided pen and keep them living like that quite a while. Chicken coop containment is especially wise with a chicken mother who is just learning the ropes herself, not having been raised by a natural mother. She may not know enough to encourage her chicks to keep warm. Leaving them alone is the riskiest option.

**Cardboard Box or A-Frame Housing.** You can place hen and chicks in a large cardboard box with a chicken-wire cover. Such a box should have appropriate litter, food, and water. It doesn't need a heat source. The hen will hover over the chicks when they need it to warm them. The big problems with box-housing are the small size and fragile construction. Instead, you may want to build an old-time A-frame chicken coop, the size of which is about 4 feet by 4 feet. It has no bottom, and no nest in it; anything else is too difficult for the chicks to get in and out of. There are slats across the opening, close enough together to keep the hen in, and aviary netting or a 6-inch board across the bottom to keep the chicks in. You can gradually phase some freedom into this setting by leaving hen and chicks shut in there for a couple of days, then letting them out together in the daytime and shutting them in again at night. In the A-frame, make available water in a chick-waterer and baby chick starter food. Arrange things so the babies don't get their feet wet. After 10 days or so you can let the cooped hen and chicks do whatever they want and they'll probably be fine.

**Chicken Coop.** The last option is a classic chicken coop. A coop ensures that the mother and her chicks don't get separated (unless a chick squeezes through the wire and gets lost). Move the family into the coop at the end of a week in the cardboard box or the A-frame, or, better yet, situate the A-frame right inside the coop and at the end of the first week, or whenever weather is suitable, just pull the board or netting off that keeps the chicks and their mother inside their house and let them have the freedom of the coop. A coop can be created by subdividing space from a regular chicken house or large bird pen or by creating a special portable unit. Ideal is a portable ground pen enclosing a little roofed box house (A-framed or rectangular) in which the hen can hover over her babies.

Good dimensions are 4 feet wide by about 6 feet long and 2½ feet high, with a wooden frame and a hinged roof. The house for such a coop can be built onto the end of it. If it has a low wooden floor and a swinging door, you can just shoo the family into it and shut the door when you want to move them. That way the coop itself doesn't have to have a bottom, which helps keep the grass under it nicer and more accessible to the birds. In good weather, put the coop right outside, moving it whenever the grass underneath seems significantly soiled or trampled. The coop should allow sunshine to enter, yet have spots of shade, and the little house should be rain-proof and heavy enough not to blow over in a wind. If the weather is cold, damp, or uncertain, put the coop in a sheltered place—inside your barn or in a shed. A coop of this design has other uses too. You can use it to isolate purebred birds for controlled breeding, or to isolate a sick bird, or to isolate newly purchased birds that are still in their quarantine period, or to house transition-size young birds.

**A Second Family:** It's almost unheard of now for chickens to set more than once a year, and that's a shame. The old-time hard-working bantam hens used to have as many as 4 families a year. After raising one family, when the early spring chicks were about 2 months old and could find their own food and get along without their mother, she chose a new nesting place, pecking and scolding the youngsters if they came near her. They would give up on being mothered and join the general flock. (Even if she doesn't want to set again, feel free to take the mother away when the chicks are 8 weeks old, or older. They will now be fine without her and can be treated like transition-age chicks from the brooder.) Such a talented chicken mother would begin laying again. When she had enough eggs she'd get broody, set again, and start another family. If I were a breeder of household poultry, I'd select for that characteristic alone!

**Chicken Housing**

Chicken houses—and all the features that go into and around them—are a big topic. Some chickens have to spend their lives in very cramped quarters.

**Batteries:** Some commercial operators keep their birds in small, individual, stacked wire cages called “batteries.” A battery-housed bird is never threatened by anything except boredom and inactivity. Batteries can't be used unless they're inside a warm building, even if they have a self-heating component. The baby chicks live in pens 5 tiers high; when they've grown larger they're moved to somewhat bigger cages stacked 3 tiers high. Food and water are provided in troughs at the edge of the tray. Battery cages can be bought ready-made or you can make them. They're certainly economical of space, but many people consider them an abomination because they don't allow a chicken to do the things chickens normally do—like scratching, dusting, sunning themselves, roosting at night, and moving around in the daytime to explore, socialize, and mate.

But even the freest ranging chickens need, and want, shelter from bad weather and night-roaming predators, for chickens are sound sleepers to the point of helplessness.
How Much Housing Space Per Bird? If your chickens will be roaming free during the day, they need only a relatively small shelter in which to sleep at night—big enough to hold their roosts. Totally confined birds, on the other hand, need much more space to avoid overcrowding them. Larger breeds need more space than smaller ones. Many birds need more space than few birds. Your bird population may be cyclical: a large crop of broilers in the spring plus your layers, but only the layers in wintertime. Figure 5–8 square feet per bird for fully confined birds in a small flock, 4 square feet per bird for a larger flock. By using a temporary chicken-wire partition, you can divide a chicken house into 2 parts during its busy cycle: one-half for the broiler crop and spring pullets being raised for replacement layers, the other half for your layers.

Using an Existing Chicken House: Check first for rodent holes; nail metal over them. Check the roof for leaks and fix as needed. Sweep the dirt out. If the building has been used to house birds in the last 3 years, give it a good cleaning before you move your own birds in. (Follow directions under "Cleaning Your Chicken House.")

Adapting an Existing Outbuilding: To renovate an outbuilding, choose one with a rat-proof floor, walls, and roof, that can keep out rain and has windows or some kind of openings for light and air. In a cold climate, it should not be drafty. In a hot climate, it should have good ventilation during the summer. You can put your chicken house inside a larger building—a large shed or barn—using existing walls where suitable and adding new ones as appropriate. Or you can build it against the outside of a larger building such as a lean-to shed (on the south side if possible).

Building a Chicken House: Keep in mind that you want a short walking distance from your home to the chicken house, because you may be going there several times a day. Situate the building so that it will be convenient for you when cleaning day comes and you want to cart the accumulated manure and litter away. Plan where you will store the feed. Art Boe is an ex-Alaska fisherman, off-and-on building contractor, former high-school science teacher, South Dakota farm boy, cow milker, and friend. His wife is a second-grade teacher and has had an Emery in her class about every other year. Here are Art's directions for building the ideal chicken house:

You'll probably need a local building permit to build a from-scratch chicken house. You can get very detailed plans from chicken books, magazine articles, state agricultural colleges, etc. A simple pole or frame building, shed type, is adequate. You can manage with a space as small as 6 by 8 feet for a dozen chickens, or 10 by 12 feet for 30–40 of them, or 20 by 40 feet for 250, which is a commercial-sized operation. Plan ahead for how you're going to clean out the manure. That means you'll probably want the roof high enough so you can get inside and shovel manure out comfortably. Slope the roof, say from 7 feet in front to 6 feet in the back, to help water run off. The rule of thumb is 1 foot of drop for each 8 feet of roof—more if you live in snow country where piled-up snow could collapse your roof.

Of Windows and Light. You'll want windows on the south side in northern climates, with enough roof overhang to keep out the hottest summer sun. To be most effective the roof overhang must slant down over the windows, creating a "V" (upside-down) or "cowl." Such a window-overhang combination will keep out the summer sun, let in the winter sun, and protect the front wall from rain. Install windows across a third to a quarter of the wall on the south side, made so that you can remove the glass in summer for additional ventilation, or easily open and close them from the outside. Windows are especially important for poultry because the male's fertility and the female's egg production are both affected by the presence or absence of light—so you want to maximize their exposure to light.

Ventilation. The more chickens you have in a house together, the more warm and moist the air is going to be in there. Chickens, especially confined ones, suffer in very hot weather and may die if the temperature in their house gets too high. They have a high respiratory rate and a high body temperature—they need proportionately more oxygen. They do not excrete sweat or urine (though their droppings are moist). A chicken breathes out her excess moisture. Moisture that doesn't have a chance to circulate out of the chicken house causes wet litter, which in turn can result in breast blisters and manure burns. In a warm chicken house, the ammonia from the manure becomes very strong, and in a very short time can result in ammonia blinding and serious respiratory damage if adequate ventilation for a confined flock is not provided. Ammonia poisoning can also retard growth, reduce egg laying, cause foot pad burns, and encourage staph infection.

So the chicken house needs ventilation enough to get oxygen in and also to get ammonia and moisture out. You will need some ventilation even in winter—windows that drop down or tip in and can be opened at least a crack. In cold weather it's best to have the ventilation on one side, to the south, to prevent chilling cross drafts. In warm climates or hot weather, you'll want to be able to open up both sides of the chicken house to get cross-drafts. Chicken wire on the inside will hold in the chickens and keep out predators and wild birds, which can carry parasites and diseases that chickens can contract. Don't use fly screens to cover the chicken house windows; they don't let enough air through to do the job in hot weather.

Climate Zones and Chicken Housing. In very warm climates like southern Texas, the southern Gulf states, and Florida, chicken houses typically have wire walls that can be covered with tarp or plastic curtains in case of windy or cool weather, and they are located under a shade tree. In the rest of the southern United States and on the extreme west coast, chicken houses are typically uninsulated and have large front openings that can be covered with plastic or windows in stormy or cold weather. (Or you can construct a more "regular" house for them—but have a screen door, screened windows, and extra screened openings in both peaks of both walls for ventilation in hot weather.)

Eastern, Midwestern, and Rocky Mountain-area chicken houses need to be well insulated (double walls with a 1½-inch insulation layer between them), tightly constructed, and protected from the wind. You can insulate your chicken house cheaply—by gluing Styrofoam to the walls and ceiling. In yet colder climates—such as Montana, the Dakotas, the Great Lakes area, and northern New England—the chicken house can benefit from even thicker insulation and electrical heating (at least a light left on) during severe winter weather. In interior Alaska, chicken houses may be built underground!
Of Insulation and Electricity. The birds will be warmer in winter if you insulate your chicken house and if it is small enough with a low-enough roof to keep the warm air near the chickens, who make quite a bit of heat themselves. Insulate by building the walls in 2 layers with air space in the middle. Air is an insulator. Or put commercial insulation material in the middle. Or fill that wall space with some different, available insulating material. Don't spend a fortune on a chicken house unless you have it to spend. For cold climates, one or more light bulbs burning at night can prevent frost-bitten combs and wattles on the roosters and help keep drinking water from freezing. With electric warmth in the chicken house, young birds can leave the brooder and move into the big house at earlier ages. You'll also find electricity useful if you live where winter nights are long and you want to push your chickens to maximum year-round production by leaving the lights on. On the other hand, you don't have to wire the chicken house. It's cheaper and simpler not to, and you'll still get eggs.

The Floor: Dirt, Wood, or Concrete. For a dirt floor, first level your ground, and then just build your house on top of that. You may be able to get along with a dirt floor, but they're hard to clean, hard to keep dry, and vulnerable to wasps and rats tunneling in; also, parasites in the ground can be harder to get rid of. Another option is a wooden floor. Building it up off the ground prevents rats from hiding underneath and gnawing through it. If rats do gnaw a hole in the floor or wall, nail sheet metal—or a tin can lid—firmly over the hole to block it. A wooden floor is warmer than dirt and dries from underneath. Chickens make a lot of moisture. But wood can warp and rot. You could reinforce a wood floor by making it of 2 layers, with building paper or insulation board between them. The other option is a concrete floor. Slope a concrete floor about 4 inches from back (where the roosts are) toward the front of your chicken house.

LITTER: You can go 3 different ways with this: Use a foot of litter to start with. Or build up litter by starting with 2 or 3 inches and then gradually adding more throughout the year in layers atop of what's already there to a total of as much as 2 feet. Or use a thin layer, which is cleaned out and replaced every week or two. This litter is very important—don't skip it. It gives the chickens something to scratch and prevents their droppings from adhering to the chicken-house floor. The litter dilutes the “strength” of the chicken manure. For chickens in a cold climate, built-up litter insulates their floor, and the decomposition and fermentation processes inside it actually provide heat for them. For the same reason, when warm weather comes the chickens will be cooler and more comfortable if you get the old litter out of there and provide fresh.

Litter Materials. Soft wood shavings, peat moss, sugar cane fiber, or some such shredded organic material is best. You can use hay, preferably that rejected by the cows. But not sawdust because it tends to be so dusty it is hard on your chickens' respiratory systems. And do not use oak shavings because they are toxic.

NOTE: Don't let the litter mold! Moldy litter can result in a serious poultry disease in which the mold organisms actually move into the birds' respiratory and digestive systems and live there. The mold organisms can also damage your health.

Stirring the Litter. Some chicken-raisers stir together the shavings and manure every couple weeks with a rake. That stirring prevents the litter from packing and promotes drying since the litter has to absorb a lot of moisture from the chicken droppings. Then when it comes time to clean out the chicken house, the litter is already more than half-composted. Other owners just let it stack up until they can't stand the sight of it any more, or the garden is going to be wanting it, and then they take it all out in a big 1-day ordeal. If you leave it alone more than a few months, the manure gets quite compacted, and it will be like spading a garden to cut it loose and get it out of there.

Nests: This is something (anything) like a wooden box, about 10 inches square, with a top and sides, but open at 1 side for the hen to enter. A slit in the top helps ventilate the nest. A slanted top prevents roosting on the nesting box with its attendant manure collection. Cover half the open side with wood, or cover all the open side with a curtain of cloth that's slit to let a chicken hop through. It should be relatively dim inside. Hens like dark, comfy, private places to do their thing in. An instant nesting place can be made by leaning a sheet of plywood, or anything similar, against the chicken-house wall. They'll lay between the sheet and the wall. Put hay, chopped straw, wood shavings, or some such, in the nesting place for the hen to nestle down in. Change the nest litter occasionally, when it gets dirty. Nail a nesting box, 2 feet high or so, up on your chicken-house wall. You can put them in a row. Supply 1 nesting box for each 4 layers—more or less. Pullets, just laying their first eggs, are liable to drop them anywhere, and that can't be helped. Some hens may be tempted to make a nest in a corner of your hen house on the floor. That is a problem because it may result in the development of egg-eating. Stop it by picking up the eggs and clearing away the “nest.”

Roosts: You'll want roosts in your chicken house. The chickens will fly up there and perch, curling their toes around the roost to hang on. (That's why it's handiest for them if you use a pole or round the top edges somewhat.) If you don't have a chicken house, your chickens will fly up onto rafters or into trees—if they can fly—as soon as they get big enough to fly that high. Since they sleep unbelievably soundly, chickens have an instinct to pick a very protected place to do it in.

Building Roosts. Basically, the perch is a long pole, 2–3 inches in diameter, set 2–4 feet off the chicken house floor. The best perch isn't made of really smooth material; the birds would have trouble hanging on. And it would be firmly nailed in place, so it can't turn. An easy-built roost is just a 2 × 4, about 12 feet long, nailed across 1 or more corners of the chicken house, as needed. But don't put roosts right on top of each other. Birds drop feces in the night. Arrange the roosts in such a way that the droppings have a clear fall to the floor. The roosts are best when they are no closer than 18 inches to a wall. Allow about 18 inches perching room per adult, heavy-breed bird. In cold weather they'll crowd and take less room as they huddle together to keep each other warm. The area right under the roosts will collect more chicken manure than all the rest of your chicken house combined. Some growers recess the area under the roosts to separate the deposits there from the rest of the litter. That arrangement is called a “droppings pit.” Some growers fence the pit at top and sides with chicken wire to keep the birds from getting into it.
Roost Height. The height needs to be right for your particular birds. High-flying bantams will like it on the high side. (If unconfined, such high-flying bantams are likely to perch in your orchard instead of the chicken house. If you let them do that a few nights, they'll want to keep doing it. It's just a matter of your preference, whether they should or not.) Yokohamas, with their lovely long trailing tails, need high perches to keep their tails out of the droppings. Bantams that don't fly much, feather-footed breeds, and Chabos need perches no higher than 1 foot. For average meat-egg breeds, if you have enough birds to need more than 1 roost, you can put them one behind the other in rising order, like separated staircase steps, at 2-, 3-, and 4-foot levels.

People Doors: You need a people door from the outside into the chicken yard, and a people door from the chicken yard into the chicken house. Or a people door from the outside into the chicken house directly, and then one from the chicken house into the chicken yard. Another useful door is a lengthwise one along the floor right behind the chicken's roosting area. That one would allow you to frequently rake out the manure from where it builds up under the roosts. Some classay chicken houses have special hinged doors that open directly into nesting boxes and allow you to gather eggs without entering the chicken house. It's all a matter of your preference.

Chicken Doors: You'll want separate doors for your chickens: little bird-sized doors (about a foot square) that are shut easily from the outside. That way, in chilly weather you can leave their doors open but close the people-sized door to minimize cold drafts. Also, for free-running chickens, such a small door keeps out large stray dogs. As an extra protective measure, close that little door at dark, after chicken time is early indeed! and then one from the chicken house into the chicken yard. Another useful door is a lengthwise one along the floor right behind the chicken's roosting area. That one would allow you to frequently rake out the manure from where it builds up under the roosts. Some classay chicken houses have special hinged doors that open directly into nesting boxes and allow you to gather eggs without entering the chicken house. It's all a matter of your preference.

Chicken Doors: You'll want separate doors for your chickens: little bird-sized doors (about a foot square) that are shut easily from the outside. That way, in chilly weather you can leave their doors open but close the people-sized door to minimize cold drafts. Also, for free-running chickens, such a small door keeps out large stray dogs. As an extra protective measure, close that little door at dark, after they've all gone in to sleep—because some night-predators are small enough to slip in through it and can make a dreadful carnage of the sleeping chickens. On the other hand, unless you leave plenty of food and water inside the chicken house before you go to bed, you'll need to get up early in the morning (chicken time is early indeed!) and open it again.

Chicken-Sized Door Design. It should be about half a foot above floor level so litter doesn't escape from it. One handy style of door is a plain flat piece of wood that slides up and down in wooden grooves. Another style is attached at the top by nailed-on leather straps or metal hinges and is held up during the daytime by a loop of twine that can be hooked on a nail situated at just the right height above. Yet another style combines a door and walkway down. You make it by sawing out your door and letting it fall to the

outside, drawbridge style, during the day, then drawing it back and fastening it shut at night. If you don't have that style chicken-door and your chicken entrance is not at ground level, then you could make a separate walkway by providing a board for the birds to walk up from ground to door level. Strips of wood nailed crosswise on the board an inch apart will help them get traction in wet weather.

Chicken-Yard Options: Basically, you have 4 outdoor options: a sun porch, a fenced dirt yard, a fenced pasture (regular or rotated), or free-running.

Sun Porch. Most chicken owners don't have the option of letting their poultry run completely free, but they want them to have some outdoor time. The most protective choice would be a sun porch. This is an outside pen or an inside pen with an attached outside run. The outside part is built at least a foot off the ground, and it has chicken-wire sides and top, and a floor of small wire mesh or wooden slats—which allows manure to fall through onto the ground below. This allows poultry to get sunshine and fresh air and prevents them from eating feces or dirt. Such a pen can be dependably sanitized. The use of a sun porch is best if you have very disease-vulnerable stock or are in a disease-parasite-ridden area. Chickens usually don't require that much protection. Turkeys sometimes do. (See "Sunporch" under "Turkeys" for more information.)

Fenced Yard: Yarding reduces confinement stress problems: cannibalism, feather-picking, egg-eating. And chickens just plain enjoy basking in sunshine (to make their Vitamin D) and benefit from exercise. Your chicken yard should be planned so that it has a portion that will be shaded and a portion that will be in the sunshine. In coldest climates, they'll be using their yard in the warmer months. Then, in extremely cold, stormy, or snowy weather, you shut the door to the chicken yard and keep them completely inside. Feed them inside the chicken house. Or, if you choose to feed them in the yard, use a covered-style feeder to keep out rainwater. A small chicken yard is a dirt yard. If it wasn't dirt to start with, it will be soon. A dirt yard is nicer if you cover it with litter. Chickens love to scratch in litter; scatter some kind of mulching material. That will also help keep it nice looking and good smelling and will inhibit possible health problems associated with wet, muddy yarding. Straw, tree leaves (not black locust—poisonous), or ground corn stalks and cobs, are cheap, fine sorts of yard litter. You then periodically add the yard litter to your compost pile, together with its nitrogen load.

Pasture. This is an excellent option. See "Water and Food for Chickens (and Other Adult Fowl)." Free-ranging is covered there, too.

Fencing for Chickens. "Chicken wire" has smaller holes than the "woven wire" you use to fence in larger animals. Chicken wire isn't as stiff as woven wire, so it takes more structure to hold it up. Posts set in the ground will corner the chicken yard. On the sides place a post about every 5 feet. Then stretch the wire around the outside, tightening it by pulling on the 3 or 4 reinforcing wires woven into the mesh for that purpose. Staple or nail (nail halfway in, then bend the nail over the wire and hammer it down) the reinforcing wire to the post. If there is any risk of predator invasion by tunneling—and to prevent birds from slipping out through holes created by dusting pits right next to the fence—bury about 6 inches of board all around the bottom.
of the fence and staple the wire to the top edge of the board. Or dig a trench all around when you are building the fence and bury a foot of the chicken wire. If the chickens have a larger pasture—say a whole orchard to run in—don’t worry: it could probably be less painstakingly fenced.

How High a Fence? The rule is this: The smaller the chickens, the higher the fence you’ll need. In general, heavy chickens need a 4-foot fence, light breeds need a 5-foot fence, and a 6-foot one may or may not hold bantams. If you are troubled with birds that fly out over the top of your fence, make the fence higher by adding more chicken wire—another foot or two at the top as needed. (Or “clip the wings” of the flyers. You do that on one wing, the outer row of feathers only. Those will be large primary wing feathers. Cut with a sharp scissors. That ruins their aviation balance. But feathers will grow back and have to be cut again after the next molt.) Or fasten chicken wire over the top of the run, and that settles the problem forever. If your chicken run has a covered top it need not be higher than 2 or 3 feet. Then you also never have to worry about birds of prey snatching a bird, or wild birds robbing chicken feed and bringing disease or parasite problems—like pigeons that may carry avian cholera, deadly to a chicken flock.

Cleaning Your Chicken House: It’s a good idea to clean your chicken house at least once a year, in the spring when the heat-producing litter is no longer needed and will become more of a problem than a help. Or you can do it twice a year: in the early spring and 6 months later in the fall. Or time your cleaning to occur after 1 group of chickens has gone to the freezer and a new batch, now outgrowing your brooder facilities, is about to arrive. Incidentally, this between-flock cleaning policy helps keep your birds healthy, if you’re troubled with disease or parasite problems.

Clean a chicken house that you’ve just bought before you move your own chickens into it. Infectious agents—disease or parasite—can live months in the dirt of a chicken house, and then move your own chickens into it. Infectious agents—disease or parasite—can live months in the dirt of a chicken house, in the soil around it, in nearby fields—anywhere the infected poultry roamed.

Chicken-House Cleaning Day. You need a warm, dry day to do this job. If you are cleaning a house that is not vacant you’ll have to get the job completely done between dawn and dusk, because the chickens will want very much to go home and sleep when the sun goes down. This tends to be a day to remember. There are 4 steps possible in your cleaning process. Do any or all as your individual preferences and situation suggest, but in the following order:

1. Give your birds their insect (external body parasites) or worm (internal parasites) medication, if such treatment is on your agenda. But don’t treat for both internal and external parasites the same day—kills the chickens. Then turn them out or move them from the quarters to be cleaned.

2. This step has to be accomplished: Shovel all manure and litter off the floor. Scrape manure off the roosts. Clean old litter out of the nest boxes. Most chicken diseases and internal parasites are transmitted through the feces.

3. This step can be skipped, or done to any degree you think appropriate: Hose down, soak, and scrub the walls and floor with a high-pressure hose, steam cleaner, or elbow grease and basic soap or a disinfectant solution. An ideal disinfectant is a lye—water mixture: 1 oz. lye/1 gal. water. This is most effective if applied hot but is also effective when applied cold. Lye water is effective against parasite eggs and disease germs, but only if the litter and droppings have first been thoroughly swept away; litter and droppings neutralize the lye, and then it can’t work against bugs.

Bleach can also be used for this purpose, as can a special-purpose disinfectant available at most feed stores. Some disinfectants are sprayed on. Read and follow disinfectant directions exactly. Some poultry-owners prefer liming the house out once a year by mixing a paste of lime with water and brushing or spraying that on. Make sure you clean the roosts, in cracks and crevices, and under loose boards with a bristle-coated brush or broom. Then let it dry out.

4. This step can be skipped: Paint the lower walls, dropping boards, pits, roosts, nests, and where the roosts and nests touch the wall, with a mite-killing solution. Follow directions carefully.

5. Let dry. Put fresh litter on the floor. Move in the old or new tenants.

Chicken Injuries, Diseases, Parasites

Injuries That Can Be Fixed: A bird with any of these problems is injured but not diseased, and is fine to eat. So you could choose not to bother with the following remedies and send the animal straight to the deep freeze. But they often can recover, if given the chance.

Broken Leg. A chick’s leg can be splinted with Popsicle sticks and masking tape. A larger bird’s leg can be splinted in the same manner with heavier-duty materials.

Egg-Bound. The chicken squats, strains, maybe spends all day in the nest looking constipated. Treatment: Pour warmed olive oil into her vent. Feed her castor oil. Then gently try to maneuver the jammed egg out.

Prolapsed Vent. This is most likely to happen to pullets who began to lay before they were fully grown. A mass of tissue will hang from the vent. It can be fixed more easily than it looks. Wash the protruding mass with warm water and a gentle antiseptic. Lubricate it with medicated Vaseline or mastitis ointment. Then push the prolapsed mass very gently back into the vent. In cold weather, dry the wet tissue will hang from the vent. It can be fixed more easily than it looks. Wash the protruding mass with warm water and a gentle antiseptic. Lubricate it with medicated Vaseline or mastitis ointment. Then push the prolapsed mass very gently back into the vent. In cold weather, dry the wet

Impacted Crop (Crop-Bound). Birds of any age that have eaten too much litter; or long, very dry, once-green feed; or other unfortunate things (like a burlap bag), can get their crop packed with it in such a way that it can’t go down, and it blocks them from eating anything else. The bird will have a distended, doughy-feeling crop and convulsive move-

659
ments of the neck. The treatment is to pour a teaspoonful of olive oil down the bird's throat and then gently massage the crop, gradually working its contents up and out of the bird's mouth. Fortunately, unlike humans (who are adapted for speech), a bird has its windpipe and esophagus completely separated, so you don't have to worry about them not getting air while you're doing this job. When you have the crop emptied give the bird water, but not food, for 24 hours. It should return to normal after that. However, sometimes the muscles of the crop have been injured, and the condition frequently repeats. In that case you give up and send the bird to the dinner table.

THE DISEASED BIRD: Most families growing only enough poultry for their own needs don't experience the variety and scale of poultry health problems that intensive growers with large numbers of the same breed and age in a small area do. So this section attempts to compromise between saying nothing and telling it all. To prevent disease and parasites, don't let your poultry go where infested bird manure from past years is located, such as in your compost pile or your garden.

If You Have a Sick Bird. Isolate it in smaller quarters to prevent it being literally picked on. Keep it warm (the Number 1 priority!) and provide dietary TLC with special bug and greens offerings. If the bird dies, burn or dispose of it in such a way as to avoid spreading the disease. Don't eat such a bird.

Disposing of Dead, Diseased Birds. Dead poultry, especially baby chicks, can be completely burned in a burn barrel. Make sure you destroy all the remains. A heavy grate on the top of the barrel can ensure that pets or predators don't drag them away. That's better than burying the carcass of a sick animal because of the possibility of it being dug up and/or of the disease organisms remaining in or spreading through ground water.

State Poultry Veterinary Lab. If you have several sick birds and they seem to have the same problem, consult your local agricultural extension agent or agricultural university extension poultry specialist. That person may refer you to your state poultry veterinary diagnostic laboratory. Every state has at least one, and many states have more than one. Call the lab to find out if they prefer you to send a couple live sick birds or one or more dead ones and what they suggest to be the method of delivery. If they will be studying a dead bird, they probably will want you to chill and freeze it as soon as possible after death. If you do have a communicable poultry disease problem, you need a prompt diagnosis, treatment for the rest of your flock, and advice on how to prevent the problem in the future.

Giving a Pill to a Bird. Open the bird's mouth, put the medicine on the back of its tongue, close its mouth, hold it closed, and wait for it to swallow.

Vaccinations. For small home poultry flocks, vaccination isn't usually necessary. Poultry diseases are much more likely to be a problem in big, commercial farms with many birds confined in a small space. Vaccines are available from poultry suppliers for a number of different bird diseases, including fowl cholera, erysipelas, Newcastle disease, laryngotracheitis, fowl pox, and Marek's disease. If you do vaccinate, give the vaccines that are recommended for your geographical area. You can buy them and the necessary equipment to inject, spray, etc., and do your own bird doctoring. To give a shot or eye- and nose-drop vaccines, hold the bird between your legs. Some of these vaccines—such as that for infectious bronchitis—use a live virus, which is given in the birds' drinking water. Be careful when giving any vaccine, especially a live one. The vaccine used for Marek's disease—a live turkey herpes virus—must be given at age 1 day to be effective. Some people are allergic to vaccines.

Pullorum Testing. That same state veterinary laboratory will test your breeders free-of-charge for pullorum and typhoid. All reputable hatcheries can advertise that their breeders have been tested and are pullorum-free. At one time pullorum disease was widespread in both chicken and turkey flocks. An infected hen lays pullorum-infected eggs that hatch pullorum-infected chicks or poults. The infected young birds spread the disease to others near them and many of them die. Some recover and will carry the bacteria that cause this disease on to the next generation. In order to break that infection cycle, responsible growers began to blood-test all their breeding stock. Infected birds were butchered. (Their meat was all right to eat.) Only uninfected stock was kept for breeding. There is no medical treatment for pullorum disease. Prevention is the only way to go.

SOME POULTRY DISEASES

Blackhead. (See also "Blackhead Disease" under "Turkeys"). Blackhead disease, which is the most widespread and destructive problem of turkey growers, is caused by a protozoan that spends part of its life cycle in the cecal worm. This is why raising chickens and turkeys together can be a problem. If your chickens don't have cecal worms—or if their cecal worms don't carry the blackhead organism—you're okay. Blackhead seldom makes chickens sick, even the ones that are hosting it.

Coccidiosis. About nine different species of Coccidia, a host-specific protozoan parasite, afflict chickens, of which three cause the problems. About six afflict turkeys, of which only two make the birds visibly sick. Most likely to be a problem for brooder chicks.

Fowl Typhoid. It's caused by a bacterium and affects many species of birds including chickens and turkeys. Because prevention and control against fowl typhoid are about the same as for pullorum, buy pullorum–typhoid-clean birds.

Paratyphoid. As with pullorum infection, there is no treatment for this. The birds start dying very young, and half to three-fourths of an afflicted flock may die. It is not possible to separate out infected birds as it is with pullorum. If this disease shows up in a flock, all the breeding birds must be disposed of and a new start made with completely healthy replacements. Paratyphoid is also called "Salmonellosis" and
can be a public health problem because humans (as well as reptiles and all other animals) are also susceptible to these bacteria. Humans usually encounter them as salmonella food-poisoning. Chicks suffer with them as a blood-poisoning disease. This organism can be spread by just about anything it gets on, animate or inanimate.

Infectious Bronchitis. This is a viral chicken disease that is highly infectious. When it afflicts young birds it damages the reproductive organs, and they will not lay normal eggs, either by exterior or interior qualities. There is no treatment, but it can be vaccinated against. The vaccine can be administered individually by nasal or eye drops, or to poultry groups in drinking water, or by dust or spray. This vaccine is frequently administered together with the Newcastle vaccine.

Newcastle Disease. This is a widespread, serious, very contagious viral respiratory disease that afflicts almost all species of poultry, especially chickens and turkeys. It could come into your poultry by wild birds or by tracking, bird purchases, equipment, feed, etc. from other poultry farms. There is no effective treatment. It is easy to vaccinate birds against Newcastle disease. The vaccine can be given in drinking water or dusted or sprayed. If you are concerned, ask your extension agent if vaccination is advised in your part of the country.

Bugs on Birds: There are chemical remedies to all these problems, which I have described with reluctance. I don't like poisonous chemicals. Parasite treatments done during molting can interfere with the bird's healthy feather development. Never treat for internal parasites and external parasites simultaneously. It will kill your birds. Wait at least 5 days between such treatments. I don't like environmental pollution. But when my kids got head lice I went straight down to the drugstore, bought some head-lice-killing stuff and used it on them (following directions carefully). Nobody likes parasites. These are hard decisions. You could burn down the chicken house, wait 3 years, and start over. You can tell me what you did that worked that didn't pollute the world, and I'll gladly add it to these methods.

Bedbugs. This brown or yellow-red insect hides by day under roosts and in nooks and crannies of the chicken house. It comes out at night to feed on the birds. Its bites cause such itching that the birds pull out feathers trying to relieve it. Use Sevin or Co-Ral.

Chiggers. These critters afflict bird and human alike. Chiggers tend to cluster on a bird's skin on its neck and back and under the wings. Too many can even kill a bird. It helps if grass and weeds are kept short.

Fowl Tick (Blue Bug). Night blood suckers like the red mite, these flat, reddish-brown, egg-shaped insects look like ticks, and like ticks, they cause loss of blood, carry diseases, and may cause paralysis. The chemical remedy is malathion spray in the chicken house.

Lice. There are 7 basic varieties of lice: the body louse, which lives on the bird's skin; shaft louse that eats its feather shafts; large chicken louse; brown chicken louse that lives on feathers and prefers southern climates; head louse on the bird's head and neck; wing louse on its wing feathers; and fluff louse in its fluff. These parasites are common, especially the body louse. These insects are either chewers or biters, and they spend their entire life-cycle right on the bird; off a bird, they die within a few hours. They lay eggs on the feathers and stick them there with a sort of glue. Depending on the variety of louse, the eggs (nits)—which are laid on the breast, the back, and under the wings—will hatch in a few days to 2 weeks. Lice eat skin scales and feathers. Chickens acquire them from being exposed to a bird or rodent, wild or tame, that has them. Lice increase faster in warm weather, but are there in the cold season, also. Too many lice can cause a decline in egg production and in the hatchability of the eggs.

Birds that are completely confined are far less likely to get them than birds that run loose. You can help your chickens in their fight by maintaining good hygiene according to the chicken-house cleaning directions. Dig in their yard enough to get them started in a new, clean, dust-bathing place occasionally (see "Dust Baths"). Dust clogs louse pores. Crumbling a handful of tobacco leaves in each nest and in bird dusting sites will help. Rotenone and sulfur (from plant nurseries) in the dusting site will also help. Since roosters don't like to dust as much as hens, they may have a worse problem with lice. To dust a bird with rotenone powder hold her by the legs with head downward. This way her feathers will open and you can easily sprinkle in the dust. Don't get it in the bird's eyes.

Lane Morgan told me, "I dust my birds with diatomaceous earth and also put some in their feed. It isn't perfect, but it helps." Another friend told me she dusts her birds with wood ashes and that controls their lice.

Insecticide powder in the feathers of a mother hen will kill her chicks when they huddle under her, so don't dust a mother. If you're going to dust her, do it well before the hatching dates. The tender skin and feathers of a chick are especially vulnerable to louse predations, and large infestations can quickly kill chicks and young chickens. Insecticide treatment will kill the lice but not their eggs, so you have to apply it again in 10 days to kill the newly hatched lice. Time the chemical treatment to match the timing of your cleaning and disinfecting the chicken house. Stronger chemicals used to treat lice are carbaryl, malathion, coumaphous (brand name: Co-Ral). Follow the directions carefully. All this effort may or may not actually succeed in eradicating a louse population.

Mites, Depluming. A severely infested bird may be nearly naked because it pulls out feathers trying to relieve the itching caused by this mite that characteristically burrows into the skin at the base of a feather. Control it by dipping the bird into 2 oz. of sulfur and 1 oz. soap dissolved per gallon of water. Be sure and get the solution down to skin-level of the bird. Repeat in 3–4 weeks if the first dip doesn't solve the problem.

Mites, Northern Fowl. This one is reddish to dark brown and is found around tail, vent, and breast. Like lice, these mites live their entire life-cycle on the bird. They suck blood and can reduce a bird's productivity and general good health. Sevin or Co-Ral can kill them.

Mites, Red. To check your hen house for these mites, look for little creatures moving in the cracks and crevices of the chicken house walls, perches, etc. You're also looking for small "salt and pepper" deposits that make a "trail" under the roost perches. If the mites are there, they hide in those cracks by day and come out at night and crawl up chickens' legs while they're sleeping to feed on them. Knowledgeable chickens will avoid sleeping on such perches, preferring uninfected places. To find out for sure, pluck a bird off the
Testing for Worms. You test for worms by having an expert examine the bird's manure. Some owners do this twice a year—in January and in July. Some owners combine the feces of several chickens to send in as a sample —on the theory that if one has them, they all will soon anyway. To send a fecal sample to a distant laboratory, put it on a piece of aluminum foil and fold the foil carefully over it. Put that into a small jar or metal container and close the lid. If the examining veterinarian identifies a parasite, he'll suggest what to do. Or you can worm the birds yourself.

Worming. Garlic, in any form, fed to the flock may help suppress worms. Some growers routinely add garlic to the flock's drinking water. Other growers feed diatomaceous earth in the same way: 2–3 T. D.E. per 1 lb. (0.45 kg) of bird feed, or about 2 c. per 50 lb. (22.7 kg) of feed, and for the same purpose. D.E. is available from Glyn Miller: 318-793-4950; 1008 Hwy 465, Sieper, LA 71472-9774; glg miller@aol.com. Steam-cleaning a chicken house at a high temperature can help kill worm eggs. Pharmaceutical worming preparations are available. Some growers believe in regular de-worming, every 6 months. Some fancy- and pet-bird owners advise feces tests, followed by worming if advised. That's expensive. Some growers are against giving chemical treatment unless the birds are definitely appearing unhealthy. Or you can hang in there with "organic" methods. If you want to use chemical treatment, you really would be best off with expert advice about which one, or combination, to use. Follow directions carefully. Overdosing with worm treatment will kill your birds. Withhold all food the night before your morning chicken-worming event.

Here are some common poultry worms:

**Roundworms.** The worms are 1½–3 inches long and live in the birds' intestine. A light infestation doesn't seem to be a problem, but too many is not good. Piperazine preparations are effective against roundworms. They can be given to the bird in water, feed, or in a capsule form. To prevent or limit roundworms, avoid using a dirt-floor chicken house and properly clean out and disinfect the chicken house floor. It can also help to manage poultry so that they are let loose on a particular range only once in 3 years. This is the most common chicken internal parasite.

**Tapeworm.** Actually there are a variety of different tapeworm species. The smallest are microscopic; the largest can be 7 inches long. These flat, white, segmented worms live in the birds' small intestine and can be quite a drain on its resources. Tapeworm eggs can live in the ground for more than a year. Infestation can be controlled by rotating poultry ranges, using an area only once every 4 years. The tapeworm uses intermediate hosts—snails, beetles, worms—in which to complete its life cycle. Poultry acquire the tapeworms by eating the infected insects.

**Cecal Worms.** These are also known as "small roundworms." They are very small and are not considered a problem themselves. Their problem is that they are the carriers for the Blackhead organism. (See "Blackhead Disease" under "Turkeys.")

**Tropical Chicken Flea.** These beasties can cause blindness and even death simply by clustering on the comb, wattles, earlobes, and around the bird's eyes. The chemical remedy is carbaryl (Sevin) in dust or spray.

**Worms:** To some extent worms are routine in poultry and can be tolerated, though they lower the flock's general disease resistance. Chicken growers in southern states have the worst problem with worms. If wild birds that have them get in to share your chickens' food, they leave droppings in the chicken pen. Chickens that pick at those droppings then acquire their parasites. Or the dropping of wild birds may be eaten by insects. If your chickens eat those particular insects, they acquire that worm variety. It helps to keep confined poultry well supplied with grit or gravel so they're less likely to peck at droppings to acquire new grit. If worms do get started in your flock the problem will spread. The worst off birds may have diarrhea and emaciation, be weak, and lay less.
nicely; figure 1 rooster per 15 hens. The extra roosters should be culled from the layers by the time the pullets are 20 weeks old if you want the best egg-laying and breeding performance. Extra roosters may hassle the pullets excessively.

**CROWING:** Roosters crow very early in the morning, in the night if they get disturbed, and at other times when the impulse takes them. In some places there are zoning laws against crowing. You can't stop a rooster from crowing; you can only stop having a rooster.

**FIGHTING:** Young males who are growing up together may look fierce but generally there are no injuries from their combats. These are ranking fights and once the issue is resolved there will be peace. Even fighting game breeds are peaceable if they have grown up together. The serious fighting happens when strange males are brought together at adult ages. Serious injury or death can be the result. The best book on the language and sociology of chickens is *Bantams* by Helga Fritzsche.

**NOTE:** Roosters are aggressive and may chase and peck small children in the eyes.

Many a time I’ve run out of the house because I heard a small child screaming in the yard, and there was a rooster flying up toward the child’s face. I wondered if somehow it was my private nightmare until I received the following letter from another mother, Becky Jacobson of Felton, DE: “Dear Carla, We had a small rooster who would fly at people once in a while, but we never though much about it. Our few chickens are usually kept penned up in the chicken yard. One afternoon they were out, and my 20-month-old daughter was playing and following her father around. She walked past the rooster and must have stopped in front of him. Before we knew what happened he flew up and spurred her in the eye. She is now blind in her left eye and the eyeball is disfigured. It’s cost us thousands of dollars and much heartache to learn this lesson.”

Roosters won’t bother a larger child; it’s your toddler or 2-year-old they would go after. Roosters raised to be fryers, that are butchered as soon as they achieve sufficient weight, don’t get old enough to be a problem in this regard. And you don’t need roosters to have eggs. Hens will lay eggs even if there isn’t a rooster at all on the farm. The eggs won’t be fertile, but they’re fine to eat, just as good as fertile eggs.

If you have a rooster that acts like he might be a danger, have him for dinner, and consider cutting off the spurs of your roosters. Or make capons.

**MAKING CAPONS:** Roosters can be castrated. It’s called caponizing them. Here’s a letter I received: “Dear Carla, How do you make capons from roosters? It seems to be a lost art. Seems such a waste to kill them small, when I understand somewhere under the right wing you cut . . . and remove something and they grow as big as a turkey if you desire. If you have this information, whatever cost, please let me know.” Well, in case you, too, are that vague about it, and also want to know the details as much, here’s the caponizing nitty-gritty.

This is indeed an old-time art; it was invented in ancient Greece. You can get a caponizing outfit, including complete directions for using it, from mail-order poultry ranch suppliers. The things you’re removing are the male sex glands that are located in a young cockerel’s abdomen. Caponizing will solve the pecking and aggressiveness problem, and the roosters will grow sometimes as much as 50 percent heavier than they would otherwise—maybe to 10 pounds. Generally, the birds have no ill effects from the operation. Caponizing is in the process of going out of fashion. It involves virtually major surgery on the bird, which may go awry. The operation results in a heavier bird, but a significant proportion of that weight is fat. The capon market is now being displaced by the new “giants,” which are large without the nuisance of the operation, and whose weight is proportionately more meat than fat.

Caponizing can be done by hand instruments or an electronic gadget. You operate when the birds are 8–10 weeks old. Operate in bright light and with the bird firmly held down onto a board or table with straps, its left side down, right side up. Pull enough feathers out to expose the lower rib area. The incision is made between the last 2 ribs from the bird’s head end. With traditional hand tools, you need a knife to make the incision, a spreader to hold open the cut, a hook to tear the membrane covering the intestines, a blunt instrument to press the innards back out of the operator’s way, and a forceps-style extractor to remove the 2 testicles, which will be located, one somewhat above the other, just in front of the kidney and near the backbone. The testicles are white and oval-shaped. A large artery runs between the two, which mustn’t be punctured.

On to a more pleasant subject: your laying flock!

**Laying Hens**

**OF BUYING GROWN BIRDS FOR LAYING:** It’s best if you buy pullets from 3 to 6 months old, so that their full egg-laying career is ahead of them. There’s many a horror story of what happened when a novice bought somebody’s worn-out cull hens. Growers don’t let go of their best chickens unless it’s your mother, and maybe not even then. Be very careful and gentle whenever you are handling birds that may have eggs inside them. If they are birds that have already begun to lay, moving is quite likely to throw them into a molt and stop their egg-laying for the time being, because chickens are strongly creatures of habit. They’ll go into that molt whether they were just starting a laying season and at full production, or whether they were near the
end of it anyway. That's why it's so much better if you buy pullets that have not yet begun to lay—or chicks.

**Egg Records:** To calculate if you're making or losing money, keep track of the values. In total, the original cost of your laying flock, plus their feed and any other expenses incurred on their behalf, is subtracted from the value of the eggs laid and the meat value of the stewing hens. Small growers generally find that if they use commercial feeds they enjoy their home-grown eggs but lose money on them. If they use home-grown foods and/or foraging, they come out ahead. Exactly how many eggs your layers will produce for you is extremely variable, depending on what breed they are, how well you feed (the more they eat, the more they lay), how much protein is in their feed, how you house them, what time of year it is, and how old they are. Commercial breeds in the 1940s averaged around 180 eggs a year. Now if a bird is laying about 20 eggs per month in her first 10 months of egg-laying, she's doing average; 300 eggs the first year is excellent. The urge to lay is fragile and can be thrown off by moving, changing feed, weather change, pullets that have not yet begun to lay—or chicks. Incurred on their behalf, is subtracted from the value of the eggs laid and the meat value of the stewing hens. Small growers generally find that if they use commercial feeds they enjoy their home-grown eggs but lose money on them. If they use home-grown foods and/or foraging, they come out ahead. Exactly how many eggs your layers will produce for you is extremely variable, depending on what breed they are, how well you feed (the more they eat, the more they lay), how much protein is in their feed, how you house them, what time of year it is, and how old they are. Commercial breeds in the 1940s averaged around 180 eggs a year. Now if a bird is laying about 20 eggs per month in her first 10 months of egg-laying, she's doing average; 300 eggs the first year is excellent. The urge to lay is fragile and can be thrown off by moving, changing feed, weather change, broodiness, or molting. And there are other factors to be considered besides pushing for egg production: feeding economy and electricity conservation.

**Egg-Laying Anatomy:** When you butcher an egg-laying chicken, you'll see the eggs-in-making inside of her. There will be tiny little yellow ones, no bigger than grains of sand, clustered together with small pebble-like ones, graduating on up to larger and larger yolks. (She builds the yolk first.) When the yolk-of-the-day is ready, it enters a long passageway where it is fertilized (if she has had the company of a rooster) and gets the white wrapped around it. Further down the assembly line, her egg gets 2 membranes added to the outside of it that hold the yolk and albumen in place. Then it goes to her shell-building station where the outermost layer is added. When she has finished building the shell, the egg moves on out to where her oviduct meets her digestive tract, just inside her vent (or cloaca). She then lays the egg, which she has spent approximately 24 hours building. When an egg is laid, its passage out is eased by a slimy, wet coating—the "bloom." When she decides to lay an egg, it generally doesn't take her long. As soon as the egg is laid, the bloom commences to dry into a thin, invisible membrane that protects the outside of the eggshell, and she cackles with the joy of accomplishment.

**Of Laying and Aging:** You can guess a bird's age by looking at its shanks: young chickens have smooth ones; older birds have larger, rougher ones. A pullet normally starts laying when she is 20–24 weeks old. She starts out making very small eggs occasionally and gradually increases egg size and frequency of laying until she is in full production. It takes her about 7 weeks to work up to full production. She's called a "pullet" until she has her first adult molt that will follow her first season of laying. After that she's called a "hen." Hens average about 20 percent fewer eggs their second season of laying, but the eggs tend to be larger, and the hen will have put about an extra half pound of weight on herself. Plan for enough replacement pullet chicks to keep the number of your eggs averaging up where you want it. A flock that is 75 percent pullets and 25 percent yearlings and older will operate at peak efficiency. On the other hand, if absolute money-efficiency isn't such a big issue for you and your hens are as much friends and pets as financial investments, you can expect them to live as long as 14 years, and to lay tolerably for maybe 7–10 of those years. The hen's lifestyle can make a big difference. If on a natural schedule and not pushed to lay, she doesn't suffer "egg burn-out"—and produces somewhat less but somewhat longer. **Laying and Bleaching:** A hen lays she loses her yellow coloration. If all her yellow is there, she hasn't started laying at all. After a few weeks of laying the yellow will be faded around her vent, eye, and ear lobe. After producing for a couple months her beak's yellow will be faded also. After 6 months of egg production her feet, toes, nails, and shanks will also be faded. When hens quit laying, the color will come back—in the same order in which it left. A parasite infestation can also cause bleaching.

**"Seasons" of Laying:** A hen that laid 240 eggs her first season will thus lay about 190 in her second season and about 150 in her third, although her feed consumption remains the same all 3 years. For peak laying efficiency, the longest you'd keep a hen is 3 laying seasons. Then you can keep her. How do you define a "season" or "year" of laying? Under natural conditions, the first egg-laying season begins (depending on when the pullet hatched) between August and March. That first season will end with a molt in September or October. Her second season starts when she begins laying again after that molt, sometime between November and January. She'll lay until her second molt begins the following September or October. Some growers cull all layers at the end of their second season. Some let them have 3 seasons. Some give them longer yet.

**Dust Baths:** Roosters don't care much for dust-bathing, but hens love to dig into warm, loose, clean dirt and take a dust bath when the weather is warm enough so they won't get chilled by doing so. They look for a fairly new place that hasn't yet acquired a flea population. They scratch there until the dirt is fine. They'll find gizzard grit at the same time. They then roll it in with their eyes closed until the feathers are full of the dirt right down to the skin. Then they shake it all out and feel purified. Instinct or experience somehow informs them that dust clogs the breathing pores of the tiny parasites that tend to afflict poultry and is therefore a perfect, natural (nonpolluting) insecticide. You can provide hens that are totally confined with dust bath facilities by furnishing a deep pan or tray with loose dirt or hardwood ashes in it. Or you can build them a "sand box" using 1-inch-thick boards, about 6 inches wide and 20 inches long. Put such an artificial dusting spot where it won't get rained on in summer and where it will be in the warmest place they have as the season cools off. They'll appreciate that. A good dust-bathing material is half fine dirt and half dry sand. Such a human-made dust bath needs to have the droppings cleaned out of it periodically and the contents changed every few weeks. You don't give chickens water baths. If you want them super-clean, supply a dusting place with pure sand in it. They'll do the rest.

**Discouraging a Broody Bird:** You could try taking away all her eggs. But a hen really in the grip of instinctive broodiness may stay on her nest even if there are no eggs in it. If you let her sit there 3 weeks, then separate the hen from the nest, she'll adjust in a day or two. Or you could let her set just 3 or 4 days and then give her the treatment. Or you could catch the moment you notice her acting broody. Put her in a pen where there is no soft, suitable nesting place and no straw or litter of any kind with which to try to make

664
Another modern method is to put her in a swinging cage. Around September the shortening days stimulate the broody mood is "broken up." Even if the setting is broken, there will be appreciated by another family.

My mother used to dump buckets of cold water on such a broody hen to try to get her to quit it and lay again. Another modern method is to put her in a swinging cage suspended from the chicken house ceiling—a tiny box that has wire sides so she'll get lots of light. It has a slatted bottom that she won't like to set on. A broody hen that won't quit no matter what may be a problem to you but might really be appreciated by another family.

**Molting:** Hens from typically very good egg-laying lines generally molt late and fast, beginning between September and October, lasting 2–3 months. Or not at all. For many chicken generations now, growers have been culling birds that slack off on their laying to molt as determinedly as they've been getting rid of ones that choose to turn broody, and the results are new genetic lines of egg-producing breeds that will lay right through the molting period. So the following discussion will be more relevant to chicken varieties of the old-fashioned sort. With them, your strongest egg-production will typically be from early spring when the days start to get long until molting time.

Chickens molt once a year. Your chickens will molt in late summer, fall, or early winter. Molting is important to chicken raisers because when the hen molts she quits laying. When a rooster molts, he quits breeding. For chickens on a totally natural cycle, springtime brings a rush of egg-laying, followed by broodiness—when she quits laying—motherhood, repeat of egg laying, broodiness, motherhood—maybe for a total of as many as 4 families a season. And then the molt. With the onset of her molt, such an ancient-rooted bird would stop laying for the year, then lose its old feathers and grow new ones for winter warmth.

The modern hen, if she is of a commercial egg-laying breed, begins to lay eggs when she's 5–7 months old. She skips the broody period, skips the molt, and lays more or less continuously for 12–15 months. Then she finally does stop or slow up for a major molt. She may stop for 3 or 4 months. At this point most commercial or very cost-conscious operations would cull her out for stewing chicken. The average chicken reaches that point at about a year and a half of age. That's why some people simply send the older crop of layers off to the freezer as soon as they molt. There's a middle ground to this. This hen begins to lay when the days lengthen in late winter (January, February) and gradually increases her laying to a peak in April and May. Then she gradually reduces productivity again through July and August. Around September the shortening days stimulate her to cease laying and use the extra nourishment thus available to grow her winter feathers. After 6–10 weeks spent in her molt, she may start laying again in October or November, or she may stay out until January or February. This is a more typical pattern.

### The Molting Sequence

Molting occurs first on the head, then neck, then breast, then body, then wings, and, finally, the tail. The new feathers push the old ones out, just like children getting grown-up teeth. It takes a hen 6 weeks to grow one of those big, primary feathers. If she loses and replaces only one such feather at a time, she'll be a long time finishing the molt and returning to lay. Under natural conditions, a very gradual molt helped survival. A chicken that lost large wing feathers only very slowly kept its ability to fly during the molt. Hens that lost several primaries at a time got it over with fastest. While the hen is molting her comb becomes less bright-colored and full-shaped. Then, when the molt is over and she's ready to lay again, the fullness and color return to her comb.

Hens that molt the latter part of July, or the early part of August, are considered good candidates for culling, because they will probably wait until December or January to start laying again, whereas birds who wait to molt until September or later, also begin lay again in December or January (when days start to lengthen). Feeding your hens lots of good green stuff may help hurry them through their molt and get them back to laying within a couple months. If you have young pullets hatched in early spring, they'll be starting to lay at this fall molting time and that will compensate in your egg production. They may go into a molt in early winter. It all depends on a combination of the particular heredity of your hen, her age, and stress factors.

### Stress-Triggered Molting

If you want all your hens to go into a molt at the same time, you can easily cause that. Just shut them up in the chicken house in the dark, especially when they've been used to running loose, and for 3 days give them water, but no feed at all. Then provide a poor-quality feed. That will do it. You won’t have to worry about eggs for a while. Most often owners accidentally throw their birds into a molt by creating some of these conditions. But some owners prefer force-molting. Natural stresses can cause molting, too. After a serious disease, the recovery phase of a bird is typically characterized by molting.

### Of Temperature, Light, and Laying

Although different breeds of chickens can be quite different about when, or if, they lay, in general, the light breeds shut down at freezing temperatures. So if you have Leghorns and you want them to do their best, set your thermostat-controlled heater in the chicken house for at least 40°F. They'll also need 14 or more hours of daylight to start laying and stay at peak productivity. Incidentally, chickens can see most colors, but not true blue; so you can use a blue light for their night warmth without disturbing their rest in the least, or to create light for night inspections.

### Daylight Hours

Chickens go to roost and go to sleep when the sun goes down—as early as 5pm in winter at my latitude (see "Hours of Daylight by Month" table). Chickens have a built-in system to measure hours of daylight and lay best when days are long—14–16 hours. The long days stimulate a pituitary hormone. In a local university experiment they were fed that hormone generously, and they not only laid all winter—they laid 2 eggs a day! If a pullet becomes sexually mature while the days are lengthening, she will begin laying eggs even before she has finished growing. If a pullet becomes mature enough to lay eggs when the days are shortening, she may not begin to lay eggs until the days lengthen again the following spring. If you choose to go natural and give your chickens a winter vacation with no

more light than what nature supplies, they'll definitely lay fewer eggs in winter—like 2 eggs per week per hen. Then spring will come and they'll all start to lay maximum at once—like 5 eggs per week per hen. Suddenly you'll be up to your ears in eggs.

**Light-Stimulated Laying.** It may not be a good idea for you to put electricity in the hen house or use it if it's already there. Lights will increase egg production but they also raise your electric bill, raise your feed bill (because laying chickens are eating more), and invite egg-laying burnout in your chickens. (Once again, I'm trying to give you all sides of the argument, and all requisite data to make your own decision and proceed on it.) In the northern United States, days are too short for maximum egg-laying during many of the fall and winter months. If you want to buy electricity for egg-making, exactly when you begin supplementing light and how many extra daylight hours you will need to provide depend on your latitude. At an average northern U.S. location, you would start supplementing about August 15. During November, December, and January, the months when days are shortest, you'd need to supply about 5 extra hours of light. You can add the hours to their day at sunset, or you can turn their light on a sufficient number of hours before daybreak and achieve the same result. You can leave the light on all night and still get the benefit to egg-laying, if turning it off is a nuisance to you. Modern timer devices that take care of turning it on and off for you simplify that problem and save electricity. If you supplement light, it's important that you do it regularly. A lighting period that is irregular, or stops, will promptly result in irregular or reduced laying, reduced rooster fertility, and hen broodiness. And it's important that you continue it until your artificial lighting neatly phases into the days of naturally increasing light.

Use a 40-60 watt bulb with a reflector to enhance the wattage. Brighter light isn't necessary to get the effect. If you have a sizable chicken house, one such bulb with a reflector every 10 feet will do. An Alaskan reader wrote me that she hangs a kerosene lantern in her hen house just about dusk during the winter. She leaves only enough oil in the base to burn the needed number of hours to supply 14 hours of daylight. Some growers, with a more sophisticated system, use a small transition light to resemble dusk. That allows the chickens to go to their roosts for the night in a natural kind of way. Bright light, suddenly shut off and leaving the chickens in pitch darkness, can create a problem as chickens may have trouble finding their roosts and steering well enough to fly up and get on them.

**Hens to Cull:** Cull non-layers and maybe also the early molters. A pullet who has never yet laid an egg has a very yellow beak and feet. As she commences laying the yellow gradually bleaches out of beak and feet. So your first culling will be of hens who for some reason do not lay eggs at all.
Early Molters. Some people think the first birds to molt should be culled, because they are often the last to return to laying. You can check your flock for culled whenever you want a chicken dinner, or periodically every few months. A pullet or hen with feathers missing from the top of her head is not molting. A bald head and bare back are the result of too many attempts at mating by one or more roosters. (The rooster grabs the top of her head with his beak in order to steady and balance himself and places his feet on her back to hold her down.) To catch early molter cullets, check during July and August. Hens that are laying lots of eggs have bright eyes, a warm, fully developed, bright red comb and wattles, and a comparatively large, moist rectum. You can fit 2 knuckles to 2 to 3 fingers between the pubic bones on each side of her rectum. (The easiest time to catch and handle chickens to do this test is at night when they are on the roost.) That's the good girl and you spare the chicken that fits that description. The chicken to be culled has dull eyes, a cold, dull-colored, shiveled comb, a small, round, dry vent, and you can only get one finger between her pelvic bones. That chicken is either a simple non-layer, or she is a layer that is in molt. You can't judge them by the feathers. A good layer may well have ragged, worn plumage because she's putting so much of her energy into egg-laying, whereas a low producer may have better looking feathers.

But that was then. This is now. Genetic lines have been selected for hens that can get through their molt without a break in laying.

Avoiding Culling. Put all your flock on the same in-and-out schedule, not bothering to check for non-layers, and butcher them all and replace with a fresh crop you've raised—say at the end of their third laying season.

Water and Food for Chickens (and Other Adult Fowl)

Water: You must have a constant supply of clean drinking water available. Even a short period of water shortage can slow growth or egg production, and chickens can take a distressingly long while to come out of such a slump. Grown chickens need twice as much water as they do food. Chicks need even more. In very hot weather, chickens pant to cool themselves (water evaporates from their lungs). That form of air-conditioning may double their previous level of water consumption. Chickens can be left for a weekend alone, but not unless you've made arrangements to laying. You can check your flock for culled whenever you want a chicken dinner, or periodically every few months. A pullet or hen with feathers missing from the top of her head is not molting. A bald head and bare back are the result of too many attempts at mating by one or more roosters. (The rooster grabs the top of her head with his beak in order to steady and balance himself and places his feet on her back to hold her down.) To catch early molter cullets, check during July and August. Hens that are laying lots of eggs have bright eyes, a warm, fully developed, bright red comb and wattles, and a comparatively large, moist rectum. You can fit 2 knuckles to 2 to 3 fingers between the pubic bones on each side of her rectum. (The easiest time to catch and handle chickens to do this test is at night when they are on the roost.) That's the good girl and you spare the chicken that fits that description. The chicken to be culled has dull eyes, a cold, dull-colored, shiveled comb, a small, round, dry vent, and you can only get one finger between her pelvic bones. That chicken is either a simple non-layer, or she is a layer that is in molt. You can't judge them by the feathers. A good layer may well have ragged, worn plumage because she's putting so much of her energy into egg-laying, whereas a low producer may have better looking feathers.

But that was then. This is now. Genetic lines have been selected for hens that can get through their molt without a break in laying.

Avoiding Culling. Put all your flock on the same in-and-out schedule, not bothering to check for non-layers, and butcher them all and replace with a fresh crop you've raised—say at the end of their third laying season.

Food: Poultry have no teeth and swallow their food whole. They have 2 stomachs. The topmost one is their crop, which stores food. The second, lower one is their heavily muscled gizzard, which "chews" the food by grinding it against small stones the bird has swallowed for that purpose.

Train your fowl of any variety to come when called by rewarding them with their food. Use a characteristic sound, whistle, hand clap, whatever. That way you can gather them when wanted and lure them into their pen when needed.

Food Containers. You can buy fancy food containers. The ones that hang from the ceiling are to prevent the chickens from scratching litter into their food or food out of the container. Or you can make a food container, like a wooden trough, for them. Or you can throw the food on their litter or on the ground and let them get exercise hunting for it. Or some combination of the preceding. Thoroughly clean and sterilize food and water containers once a week for chicks, once a month for adult birds—more often if the containers get visibly disgusting. To do this remove any clinging manure with a scrub brush, then wash the container in a sink or tub that holds 2/3 c. regular liquid bleach per 5 gal. water along with some laundry soap. Let them drip dry. Refill and serve. Don't pour fresh feed of any sort on top of uneaten older feed ever. Rotate your feed containers so that one is picked clean before you refill it. Don't feed your poultry moldy food.

Of Food and Egg Production. The better your layers are fed, the more eggs they'll produce. To make a laying flock pay, feed them to the hilt. For every 12 percent you cut back on their food, they'll slack off on laying 25 percent. And they must have a balanced diet to grow well or lay well: carbohydrates, protein, calcium and phosphorus, trace elements, and vitamins. Old-timers say the time of day you feed them matters, too: that for best production you should feed them amply twice per day, once before they go to bed, and again have food and water waiting for them when they rise in the morning. (Since chickens are such early risers, you'd probably want to set that food out the night before, after they've gone to sleep.)

Commercial Feed. It's available in differently formulated offerings for baby chicks, growing fryers, growing pullets, layers, and breeders. There are also all-purpose feeds available: for young birds (up to 5 months) and for the older flock. An adult chicken eats 85–110 pounds of feed per year. If you're wondering how much food is enough simply take note of how much they're eating. If there is no food at all left over at night or in the morning, give them more. If they are not eating up all their food, decrease it. That same principle works with home-devised diet.

Commercial vs. Home-Grown Feed. The notion that you must have modern, commercially prepared, or mixed-by-formula chicken feed to own chickens is an insult to the intelligence and honor of thousands of years of chicken farmers who domesticated the animals and kept the genetic lines going right up to the time-line doorstep of our present era. That notion is, however, good business for commercial feed sellers. And it is certainly true that their feeds are carefully researched, carefully prepared, and more foolproof than your own. It is also true that, using commercially prepared feeds, you can grow your meat-bird to the desired weight faster and on less pounds of feed than you can on home-devised or foraging diets. And it is also true that commercial feed is much more expensive than whole grain you
purchase directly from a farmer you know, and far more expensive than the grain and other foods you can raise yourself on a small plot of ground. Using commercial feeds is a luxury that risks bankrupting your operation. On less concentrated, cheaper, home-devised diets, poultry will ultimately achieve their target weight, albeit slower and with perhaps less fat, which you don’t need anyway. Layers may not lay the absolute most of which they’re capable, but they may not burn out as fast to become culled either. I’d hate to see society come to some kind of crisis and not have the know-how to keep their livestock going without centralized poultry-feed processing and packaging plants.

Feeding Table Scraps. Chickens will eat all your peelings, sour or sweet milk, pickles, meat scraps, and rancid lard. They love all sorts of overripe or damaged vegetables, cull fruit, pea pods and vines, thinnings from the garden, general table scraps, and refrigerator throw-outs. They’re not so keen on onions, green peppers, cabbage, or citrus fruits. And don’t feed them moldy food. (Feed those to pigs or compost.) Marilou Heath of Rialto, CA, wrote me: “We were out to dinner today. The waitress looked odd when we asked for a doggie bag—all we had left was banana peels, melon rinds, and French fries, nothing that any self-respecting dog would eat. Had to explain it was actually for the chickens. And the bunny loves banana peels.”

Grain. A chicken’s gizzard is ideal for grinding grain—as long as the bird can get grit. So you don’t need to grind it (or have it ground) for them. An exception to that might be for small bantams who sometimes have trouble eating very large grains and prefer them to be ground. Young chicks also need it broken up. A mixture of grain is better than a single grain. Coarser grinds are better than flour or mash grinds, which may stick to the beak or get wasted. Corn is probably the easiest to grow at home. A traditional feed called “scratch” consists of a rather flexible mixture of grains—such as field corn, buckwheat, and sorghum heads. Or corn/oats/barley. Or corn/oats. Or corn/wheat. Or corn/oats/wheat. Or corn/wheat/sorghum. Or your own formula. But corn can be a peril as well as a blessing. Birds love corn, but it’s a high-fat, low-protein food. Fat roosters don’t breed as well. Fat hens don’t lay as well. To a real extent, what you feed them will be reflected in what you get out of them. If you want protein out of them, you have to put protein into them.

Contrary to popular impression, a chicken does not have to have grain to live, though grain is a rich food that certainly encourages them to grow well and lay generously. The most essential time of year to feed grain is winter, when chickens need extra nourishment to keep themselves warm. The best time of day to feed it is just before they go to bed. That encourages them to come home to roost, and to lay an egg at home in the morning. An old-time way of fixing the quantity of grain to feed was to feed only the amount of grain the chickens would clean up in about 30 minutes. In winter they made that 30 minutes in the morning and then another 30 minutes at night. The grain can be fed in a trough or scattered in the litter or on the ground. Hopper feeding keeps confined birds out of their droppings. On the other hand, tossing the grain into the floor litter gives confined birds something interesting to do and reduces the tendency to pick at each other, satisfies their instinct to scratch, and provides them more exercise.

Feeding Chickens in Winter. You can’t get something for nothing. When there are no or few natural foods for the chickens outside, or the weather is too bad for them to get out, they need commercial feed, plus grain, water, and grit. Or, if their menu is to be home-devised, feed them protein, grain, and greens. In winter they’ll enjoy vegetable peelings; cooked cheap bulky vegetables like squash and mangel (stock) beets; warm, cooked cull potatoes; and sprouted grain. They’ll also benefit from a source of calcium. They’ll eat some old alfalfa hay and get all the grass and weed seeds mixed in there. If they aren’t on commercial feed, make sure they can get some sunshine or Vitamin D. Chickens that are allowed to be out all winter, freely ranging, don’t lay as many eggs as confined (deep-litter or battery-style) chickens. Still, such a hen, if she’s of a good-laying breed, may still lay 200 eggs or so, which is not shabby. The lower the temperature, the more food your poultry need to consume just to be okay. Each degree of temperature drop in their environment forces chickens to eat proportionately more food to maintain themselves. In a below-freezing environment 100 heavy breed layers would require an extra 375 pounds of feed per month. For the same cost you could insulate the chicken house better and you’d get more eggs, as well as saving some feed expense.

Sunshine: In the dead of winter my mother used to feed both me and her chickens cod-liver oil, which contains Vitamin D. Modern research has explained what old-timers knew from trial and error: chickens, like people, make Vitamin D from sunshine. If they can’t get out to have sun shining on them, they’ll have to be given cod-liver oil (or some other D supplement) or commercial chicken feed. If chickens are low on D, they won’t thrive and they won’t lay, or they may lay thin-shelled eggs. Young ones may grow with weak bones that result in leg deformities. The easiest solution is to provide them with an outdoor run since sun shining through glass panes doesn’t do the job. But if you live in northern Alaska and in winter being outdoors is not an option, then give the vitamin.

Free-Roaming vs. Confined Chickens: Most chicken growers don’t have room enough for roaming chickens, dogs, goats, or anything else. Such are these modern, crowded, times. Chickens that roam, at least some of the time, look the happiest and healthiest. Farm-raised chickens that were mothered by real chicken mothers are most knowledgeable about foraging. Bantie breeds tend to take it naturally, but most chickens can learn to do some. In summer my chickens range all over the farm, looking for weed seeds and insects. Chickens don’t understand about property lines. If you have close neighbors, perhaps you can compromise by just letting the chickens out the last few hours before sundown, so they won’t have time enough to get too far from home. No matter how good at foraging your poultry are, don’t leave them completely on their own. Chickens can get into insect baits and rodent poisons, and they should not feed near where crops or orchards have recently been sprayed. Give them some food in the chicken house to remind them where they are supposed to lay their eggs and where home is. The best food supplement to free-ranging chickens’ diets, besides table scraps, is plain old grain, offered morning and night.

Of Roaming Chickens in a Garden. They’ll take a toll by pecking tomatoes and strawberries. You have to decide for yourself if the bug patrolling is worth the price you pay in
sharing your produce. You'll definitely want to keep chickens out of the garden just after planting corn, beans, peas and beets, until the young plants are well started and no longer have the remnant of a seed at their roots. Otherwise, chickens will dig up and eat the seeds. Some people let only a select few of their chickens (banties usually) do the garden patrol. It really depends on how many chickens you have, how big a garden you have, what type of produce you're growing there, and how bad your bug problem is. To keep them out, you'll either have to fence the chickens in somewhere else, or fence them out of the garden.

Green Food for Confined Chickens. They love green food of any kind, from plain grass to dandelion greens to even chopped nettles. In summer, feed them from your garden: carrot tops, pea shells, surplus Swiss chard. If you have, how big a garden you have, what type of produce a select few of their chickens (banties usually) do the garden patrol. It really depends on how many chickens you have, what type of produce

The domestic chicken is derived from an East Asian jungle tree are poisonous to chickens.

Robert Plamondon is both a tech writer and a free-range poultry grower. His website provides FAQs, a description of his own setup, and reviews of recommended books: robert@plamondon.com; www.plamondon.com. ATTRA's info on pastured poultry is at www.attra.ncat.org/attra-pub/pasturedpoultry.html.

Herman Beck-Chenoweth's Free-Range Poultry Production and Marketing (1996; 740-596-4379) presents info on production and direct selling for the producer/processor. His system is 8 x 18 ft. wooden skid houses enclosed with chicken wire and with gabled tarp-covered roofs and litter-covered wood floors (300 birds per house). He opens the house doors every morning and shuts the birds in every night. He uses a strong perimeter fence around the field to contain wanderers, but usually the birds forage close to home and return there at night. He harvests continuously. The system is described in more detail at his website: www.free-rangepoultry.com.

Join www.pasturepoultry@yahoogroups.com, and the American Pastured Poultry Producers Association (membership $20/yr; good-quality newsletter, Grit); for more info: PO Box 1024, Chippewa Falls, WI 54729; grit@apppa.org; www.apppa.org.

You can buy or make movable cage/shelters. Henspa offers a wide choice of backyard-sized chicken-house/yard combos with wheels hidden inside, ice-free water supply, feeders, and nests inside: Henhotel (25 hens); Henhaven (5 hens); Henspa (10 hens). There's also the Henspa Deluxe for a vertical garden and portable poultry/swine paddock-fertilizer generator, the Foodspa: www.henspa.com/.

Brower sells a PVC pastured poultry hoop pen that rests easily, moves around freely, and lets birds graze yet stay cool on scorching hot days and dry on wet days. in any form, because of rampant water pollution these days. Don't feed soybeans unless they have been heat-treated because raw soybeans contain compounds that can be poisonous to chickens. Don't feed them cottonseed meal because it contains gossypol that will poison chickens.

**Milk Protein.** Chickens love sweet milk, sour milk, or buttermilk. If you're offering milk for protein, make sure you give enough. Chickens on a completely noncommercial diet would love a minimum of 1 gal. milk per day per 30 birds, plus all the grain they'll eat (or other substantial food like baked squash and mangel beets), plus ample access to pasture, or being fed cut greens daily (or good leafy, green hay in wintertime). Powdered milk cannot fully meet this need because it is missing the whey (liquid), which contains a part of the nutrients the chickens need. Don't serve milk in a galvanized container because of its tendency to turn acidic. Serve it in plastic, enameled, glass, ceramic, pottery, or stainless steel feeders.

**Calcium:** Growing chickens, like children, need calcium to make bones. Laying hens need calcium to make strong eggshells. If your layer's diet becomes calcium deficient, she'll quit laying within 2 weeks. You can supply a partial calcium supplement by drying eggshells until they're brittle, breaking them up thoroughly with a rolling pin, and then feeding them back to the chickens. (Lane Morgan told me she bakes them because baking makes them easier to crush and, she figures, changes the taste enough to make the chickens less likely to become barnyard egg-eaters.) But a chicken needs more calcium than what she can get from just her own recycled eggshells. Ground oyster shells or ground limestone are good for the calcium content, too. The chicken partially grinds the oyster shells in its gizzard and absorbs what calcium is released that way. The old-timers met this need by feeding surplus dairy products, which are rich in calcium and phosphorus. There can't be such a thing as too much calcium in a chicken's diet, so offer oyster shells, milk, etc.

**Egg Eaters.** Overcrowded chickens, with insufficient space to run and insufficient gravel in their diet, are more likely than others to develop into egg eaters. Make sure there's plenty of calcium in their diet, provide nests that are quite dark inside, and gather eggs frequently, even as often as 3 times a day. A chicken who has learned the habit might learn differently if you plant an egg filled with red pepper to give an experience she won't forget. A drastic treatment to isolate it until it's healed, because chickens are likely to devour an injured bird if it can't get away on its own. For minor problems the iodine alone may do the job, as chickens hate the smell of iodine. Or use the commercial product, "Anti-Pick Lotion," for this purpose. You apply that to the feathers and the picked areas of chickens. It encourages healing of the wound and is so distasteful to chickens that it discourages the other birds from further picking. Put your anti-pick substance on as soon as you spot a problem.

Picking is less likely if the birds' diet is adequate with plenty of protein and salt. Crowding can make it worse, and boredom contributes. The combination of bright lighting and confinement can cause it. That's why free-ranging birds are much less likely to cannibalize than closely confined ones. Keeping feed before the chickens helps keep their beaks productively occupied. Giving them opportunities to scratch grain out of their litter may distract them from paying so much attention to each other and keep them occupied. To stop an individual pecker who is worse than most, clip the little sharp end part off the tip of that bird's beak with a fingernail clipper. (See "Debeaking.") Or send it to the stew pot. The best thing is not to let cannibalism get started because, like all chicken habits, once they learn it, it's hard to stop.

**NOTE:** Birds can get very sick from consuming even small amounts of gasoline, engine oil, or polish. This sort of thing can float on top of a puddle and be taken in by a bird drinking puddle water. Even a small amount can cause chronic gastrointestinal illness to the bird. Antifreeze, rat poisons, insect poisons, plant poisons—any or all of these could be deadly to your poultry.

**Eggs**

Have you ever watched a chicken lay an egg? It's rather a private act, I suppose, but when I was a little girl about 6 or so, I got a great desire to see the egg come out. I patiently waited, every morning that I had the chance, hanging around for days behind a little red hen who laid her eggs in a rather exposed nest. Finally one day it happened: I saw the egg come out! Not as dramatic as watching kittens, puppies, or baby goats come out, but a wonderful moment nonetheless. I was impressed with the serious effort the act required from the hen and her immense relief when it was all over. She jumped up from her nest and walked in a
happy and excited way all about, cackling her head off over the joy of it all. So, if you want to meditate on where eggs come from, that's where, and you can rightfully be grateful to the hen because she worked at it.

**Finding Eggs:** A basic principle for gathering eggs from any poultry is this: the more you take, the more they lay, and the less they go broody. And you should gather every day to make sure the eggs are fresh. If your birds are confined in a hen house, it's easy to gather regularly and gather often. If not, it can be an adventure. All hens like to lay where there are already eggs. That's helpful. But they'll often pick a new nest spot if you keep emptying it completely of eggs. Then you'll have to discover it all over again. So leave an egg in there marked with a pencil so you won't let it get too old before gathering that one and using a new one. Homestead mail-order suppliers often offer wooden or plastic "eggs," or a smooth white stone can serve the purpose.

The biggest trouble with letting chickens run loose is that sometimes you never do find the eggs—until mama shows up with a family, or you discover a heap of woefully overripe ones. The best way to keep free-running chickens laying in the hen house (besides shutting them up completely, which would probably throw them into a molt and decrease production), is to feed them in there generously (keeps out night predators, too). They will tend to lay their eggs first thing in the morning. Waiting a few hours after their rising hour to open their door gives you extra security. Then you can let them go on their foraging way. It also helps if you have a roomy, nice chicken house with lots of nesting boxes made the way hens like them, and plenty of clean straw bedding inside.

**Various Eggs:** Your home-grown eggs may vary considerably in size, color, and freshness. Pullet eggs are smaller than those the hen will lay later. You can tell when a pullet starts to lay eggs because she gets broad across the bottom (same thing happened to me having babies). If you have a small and varied flock you'll learn to recognize each hen's egg—they are a unique combination of size, shape, and color. Then you'll know who's laying and who isn't. (But the heredity will be an undesirable mish-mash.)

**Bizarre Eggs:** You may get an egg with 2 yolks. It's fine to eat—just trying to be twins. You may get an egg covered with chicken poop—just wash it off. Your egg yolk may be darker in color and stronger in taste and the egg white thicker and firmer—the whole egg held together more firmly—than store eggs. That would be because your chickens have had access to a richer, more natural diet than commercial layers, which are required to do their most with the least (and the egg shows the difference). Your home-grown egg may have a speck of blood. That's a hereditary characteristic in some chicken lines and doesn't affect the edibility in the least. The egg may have a distinguishable white spec. In that case, it was a fertile egg and, given the right conditions, could have become a chick. Such an egg is also fine to eat. Your egg may have a weirdly shaped shell. It's good to eat, but don't incubate such eggs because you don't want that hereditary trait passed on—besides, they are less hatchable. Your egg may have an egg inside an egg, a curiosity caused when an egg backs up in the oviduct for some reason and thus goes through the last couple production stages twice. The only obviously undesirable egg is one that has a half-developed chick in it or is full of rotten gunk. Otherwise, if you're in doubt, you have to test for freshness. **NOTE:** Use cracked eggs only if it's just the outer shell that is cracked and the inner membrane is okay. The membrane is okay if there isn't any egg oozing out the crack. But just be on the safe side, cook such eggs thoroughly or use them in foods that will be cooked.

**Fresh or Rotten?** If you discover a nest where some hen(s) hid and laid 25 eggs, then the problem is to distinguish which eggs are still fresh enough to use:

**The Bowl Test.** The simplest way to determine freshness is to put eggs on the menu. Start by examining the eggs carefully. Usually you can tell a bad egg without even breaking it clear open. It's hard to crack because the membrane inside the shell has become tough. It may smell bad, and if you just start to crack the shell, yucky stuff may come oozing out. Okay, those you toss. Then come the marginal cases. You have to shell them into a bowl to find out for sure. You're bound to get surprised sometimes: an egg that looks dirty and old will turn out to be just fine, and vice versa. If the egg in your bowl doesn't have a funny smell and looks average, I'd say go ahead and use it. So pour it out of the small bowl into your mixing bowl, and go on to the next egg. Incidentally, if the last egg was a rotten one, be sure and rinse your testing bowl well before you pour another egg into it.

**Float Testing.** If you want to know about the egg without opening it—which, once you've encountered hydrogen sulfide, is understandable—use the float test. Put the eggs in a pan of water. Fresh eggs will lie on their sides on the bottom of the pan. If an egg's a few days old, one end will tip upwards. If stale, an egg will stand on end. If plump rotten, it will float. This is all because an egg contains an air cell at the large end of it. Eggsheads are perforated through by tiny holes that would be needed by the chick for breathing. Thus, with time, a part of the liquid content of the egg evaporates, the white and yolk shrink, and the resulting
new space is filled by an enlarged air space. But, like life, this float test is not 100 percent dependable.

**Candle Testing.** A more sophisticated system is to "candle" the eggs. (See "Candling the Eggs" for details.) If the contents do not fill the shell, the egg is not perfectly fresh. As with the float test, the larger the airspace (which is now made visible), the older the egg. The yolks should be perfectly clear and round in outline. Another candleing sign for freshness is yolk movement: in an older egg the yolk moves about more freely. An egg that has been stored a while will show some shrinkage, however, even if it has been kept chilled and fresh.

**Selling Your Eggs:** In general, government regulations permit you to sell eggs to friends, neighbors, and at a roadside stand without a license or supervision. If you acquire 3,000 birds or more and sell to licensed outlets like restaurants, bakeries, and grocery stores, then you will need to comply with state and federal laws and should inquire to find out what they are.

**NOTE:** The USDA, because of increasingly frequent cases of food poisoning from salmonella in some commercial eggs all over the country, now advises against eating raw eggs in any form. I was asked to delete from this book every recipe containing raw or undercooked eggs, and I have done so. But I did it sadly and reluctantly, because egg nogs, egg drop soup, and uncooked eggy ice cream were favorite recipes of mine, and because salmonella in eggs has not been a problem for people with a small family flock and their home-grown eggs. Salmonella poisoning from eggs is most likely to be a problem when 4 conditions are present:

- Commercial eggs are used.
- Many eggs have been combined, as in a scrambled egg mix.
- The eggs are then allowed to sit at room temperature for an hour or more before cooking.
- The eggs are undercooked.

These 4 conditions give one bad egg a chance to contaminate the whole batch—followed by a perfect growing environment for the salmonella bacteria. Poisonings of this sort have occurred, for example, in scrambled eggs prepared ahead for a church breakfast. But for absolute safety, the USDA urges you not to eat uncooked or undercooked eggs in any form, because to kill salmonella, the egg or food with egg in it must be heated to 140°F for at least 3½ minutes—no more soft-boiled eggs. How does the salmonella get into the egg? Last I heard, they still weren't sure. The USDA info number about this is (800) 535-4555.

Salmonella: This variety of food poisoning has been a problem in the northeastern United States now for more than 10 years. Recent research has traced it to commercial Grade A eggs. To be precise, a report by the Centers for Disease Control (CDC) states that cases rose sixfold between 1976 and 1986, from 549 to 3,579, and that during the last 2½ years prior, 77 percent of the salmonella outbreaks that could be traced to any particular food source were found to have been caused by eggs that had contained salmonella. It used to be thought that the problem was cracked or dirty eggs. The latest CDC study has caused researchers to hypothesize that the bacteria are actually being transmitted to the eggs before the shell is formed. To kill salmonella, the internal temperature of the egg must be raised to 140°F for at least 3½ minutes. It is extremely unlikely that your personal flock of birds has this problem.

**Eggs as Deer Repellent:** Margie Minard of Mt. Vernon, OH, told me eggs help those who have problems with deer in their gardens. Her husband read that one of the huge lumber companies found out that deer hate eggs and had developed an eggy spray for their seedlings. She said "We've just been throwing our used eggshells out here and there in the garden and among the berry bushes and the deer don't come near any more!"

**Egg-Using Recipes:** When eggs are in season (spring), you can make scrambled eggs, deviled eggs, pickled eggs, French toast, puddings, crepes suzettes, eggnogs, ice cream, homemade mayonnaise, potato salad, or put plain old hard-boiled eggs into packed lunches. If cholesterol consumption is a worry in your family, feed some or most of the yolks (that's where all the cholesterol is) back to the hens or pigs and shift the recipes to use pure or mostly egg whites. In other words, you could make scrambled eggs for a family using 6 whites and, for example, only 2 yolks. Chicken eggs are 10.5 percent fat. Eggs should be cooked at a low or moderate temperature because a higher temperature makes the egg tough. When eggs are used to thicken liquids, the mixture is generally cooked over hot water kept just below the boiling point to prevent curdling or separation of the liquid.

**HARD-BOILED EGGS** Fresh eggs, unlike cold-storage eggs (grocery store), are hard to peel when hard-boiled. That's because they haven't lost any fluid to evaporation—the inside of the egg doesn't have any space between it and the shell—so part of the white layer tends to come off with the peel. The way to avoid this problem is to let the eggs destined for hard boiling get at least 5 days old before they hit the hot water. Then put your eggs into cold water (not more than 2 or 3 dozen in one container), bring to a boil, then simmer, covered tightly, for 10 to 15 minutes. Cool on the stove for half an hour. Put into very cold water and leave for 5 minutes. They should now peel easily. If the egg forms a greenish colored layer around the yolk, the egg has been cooked too long or at too high a temperature. This color can also develop if you store the cooked egg. It is unattractive, but harmless.

**SHIRRED EGGS** Melt 4 T. butter and distribute it among 6 small custard dishes or muffin containers. (There used to be a regular product for this called an "egg shirrer.") Dust the buttered bottoms with dry bread crumbs. Break 2 eggs into each hole. Don't stir. Sprinkle with salt and pepper and set them into a moderate oven until thoroughly set.

**EGG CREPES** Combine 6 eggs, 1½ c. unbleached or whole-wheat flour, ½ c. loosely packed brown sugar or a couple tablespoons honey, and 1 c. milk. Beat until there's air captured in it for lightness. Pour just enough to make a large, thin pancake onto a greased frying pan or griddle over medium low heat, turning when one side is done. Serve flat or rolled up with butter and honey, fruit sauce, syrup, Devonshire cream, or cream cheese inside.

**Old-Fashioned Rice Pudding** Boil 1 ½ c. uncooked rice in 2 c. water (with a pinch of salt) over strong heat until water is absorbed. Then add 5 c. milk and continue cooking over low heat until milk is absorbed, stirring occasionally. Beat 5 eggs, add 1 c. sugar, and 2 t. vanilla. Move rice to an oven casserole dish. Fold in egg mixture. Add 1 c. raisins (optional) at this point. Sprinkle cinnamon on top, and bake at 350° F for 45 minutes.

**SCRAMBLED EGGS FOR A CREW** Beat together 1 dozen eggs, 1½ c. milk, 1 t. salt, 1 rounded T. flour, ½ t.
whites and yolks while the eggs are still cold, but wait until peaks that stand by themselves. First you get soft peaks, salt or cream of tartar. The whites are "stiff" when they form steady, high speed. They will get frothy and gradually

Separating Eggs. Separate whites from yolks by cracking the egg over a bowl and gently breaking the shell in two, keeping the yolk in one half of the shell. Let the white drain into the bowl by pouring the yolk from one shell to the other.

Beating Egg Whites. To get the highest peaks, separate the whites and yolks while the eggs are still cold, but wait until they are at room temperature to beat them. (Keep the yolks for other cooking.) Beat the whites with an egg beater at a steady, high speed. They will get frothy and gradually thicken. You can quicken the process by adding a pinch of salt or cream of tartar. The whites are "stiff" when they form peaks that stand by themselves. First you get soft peaks, then harder ones. Home-grown egg whites whip much faster than store-bought ones.

Custard Secrets
1. Custard should come out firm rather than runny.
2. Check for doneness by inserting a thin knife into the center of the custard. If it comes out clean, the custard is done. If any egg clings to the knife, the custard needs more cooking.

3. If it's cooked, but still runny, there weren't enough eggs for the amount of milk. (Most recipes are based on large-size eggs.) Or you used too much sugar, which can also cause the custard not to set up properly. Or the cause of runniness can be that your custard was stirred during baking.

4. If you want a soft custard, stir the mixture from time to time as it cooks. If you want a firm custard, leave it alone. If you want it extra firm, use more eggs.

**Homemade Easter Egg Dyes:** Wilma Litchfield, my Utah pen pal for years now, wrote me about this. She says safflower (plus 1 t. vinegar) gives pale yellow; orange marigold petals make yellow; turmeric (plus 1 t. vinegar) makes golden yellow; yellow marigold petals make greenish yellow; red onion skins make a rusty red; sandalwood gives a salmon color; cranberries (plus 1 t. vinegar) make a pale gray-purple; blueberries make a bluish purple; raspberries make a pale lavender; walnut hulls cause a nice chocolate brown. Dyeing with red cabbage leaves gets the best color if you add 1 T. alum.

To begin, wipe egg with vinegar, rinse, and pat dry. Put each egg on a cheesecloth square together with the dyestuff you want to use for that egg. Put egg in center of dyestuff. Pull up sides of cloth around egg, tying ends with a rubber band. Put egg packages in a pot of cool water deep enough to cover them completely, heat the water to boiling, and continue cooking at a slow boil for at least 10 more minutes. Take eggs out of water, and cool packages under cool water. (Use white vinegar to avoid adding unwanted color.)

(See Chapter 5 for more information.)

No matter what it is, or how unimportant you may think a particular item is, somewhere somebody collects it. And no matter what the subject, somewhere somebody has written a book about it. At least, that's my theory. On this subject a good reference is *Natural Dyes and Home Dyeing* by Rita J. Adrostco (Dover, 1971).

Here are some specific Easter egg recipes.

**DEVILED EGGS** Cut hard-boiled eggs neatly into halves lengthwise. Remove and mash the yolks and season them with salt, pepper, mustard, grated onion, or what you prefer. Roll the mashed, seasoned yolk into balls of the appropriate size and put one ball into each half egg-white. Serve spread out on a platter.

**VEGGIE OMELET** 4 eggs, pepper, 2 T. butter, chopped vegetables (such as onion, tomato, green pepper, mushrooms, broccoli, shredded sprouts), grated cheddar cheese. Beat eggs. Melt butter in skillet and add egg mixture. Add your choice of vegetables to one side of the omelet and season with pepper. Cook slowly till underside is barely brown, then sprinkle on the cheese and fold the plain side over the vegetables and cheese. When the egg has fully cooked, serve.

**Separating Eggs** To avoid sticking to the pan, use enough oil to flow around the pan. And use a skillet with flared sides, rather than a straight-sided one.

**Omelet Secrets** To avoid sticking to the pan, use enough oil to flow around the pan. And use a skillet with flared sides, rather than a straight-sided one.

**ONION SKIN PACKAGES** Wrap eggs in onion skins, then in a cloth, and then tie with string. Onion skins are a natural dye, and the string presses the skin against the egg, making patterns also. Boil these eggs in the cloth package (they can start out uncooked), and then unwrap for lovely surprises. (Can be dyed again with food coloring for further decoration.)

**FOOD COLORING AND VINEGAR** Submerge a hard-boiled egg in a cup of water that has a little vinegar in it. (Vinegar sets the color.) Using a dropper, drop the food color onto the egg. It spreads and makes amazing patterns. Rinse the eggs afterwards to remove excess color. From Carol Kahn, Vernon, OR.

**PRECOOKED DYES** From Mrs. Linda Crabtree, Kettering, OH: “Natural dye colors turn out much softer looking than commercial egg dyes and often give you a spotty or speckled finish. Dyes should be cooled before using, preferably overnight. Add just a little vinegar to fix the color. (Don’t boil vinegar in aluminum.) Examples: 5 red cabbage leaves plus 4 c. water equals aqua color and an egg pattern like tie-dye material. Or boil the outer dry skins of 2 medium onions for an orange dye. Orange peel gives you a light yellow dye. Yellow Delicious apple peelings make lavender with soft rust flakes. Thyme boiled makes a pale graying yellow-orange dye. The possibilities are only limited by your imagination and willingness to give it some effort.”

**DEVILED EGGS** Cut hard-boiled eggs neatly into halves lengthwise. Remove and mash the yolks and season them with salt, pepper, mustard, grated onion, or what you prefer. Roll the mashed, seasoned yolk into balls of the appropriate size and put one ball into each half egg-white. Serve spread out on a platter.

**Omelet Secrets** To avoid sticking to the pan, use enough oil to flow around the pan. And use a skillet with flared sides, rather than a straight-sided one.

Orange peel gives you a light yellow dye. Yellow Delicious apple peelings make lavender with soft rust flakes. Thyme boiled makes a pale graying yellow-orange dye. The possibilities are only limited by your imagination and willingness to give it some effort.”
**DANDELION AND PINE NEEDLE EGGS**  "First send the children out to gather lots of daffodils, dandelions, needles from fir or pine trees, and big, strong leaves. Then take your uncooked eggs and wrap them with the leaves, pulling in the flowers and needles against the eggshell under the leaf; cover the egg by wrapping more leaves around the whole thing. Tie string around the leaves to hold them on. Boil until the eggs are hard-cooked. Remove from water, take off the string, and unwrap the leaves. The pine or fir needles will have produced a design on the egg. The green leaves produce yellow. Daffodils and dandelions produce deeper orangish-yellow coloring. For deep dark blues and purples, squash blackberries or blueberries on the egg and then cover with leaves or onion skin. The leaves can be used again and again. Boiling longer produces richer, darker shades. The eggs are beautiful and each is different. We also like to dye the big goose eggs. The geese lay about Easter time and it's fun to have the big eggs." All this information is from Nancy Dyer of Corbett, OR.

**FLOWER-PATTERNED EGGS**  "My great-grandmother taught my mother this. You need brown onion skins, small spring flowers like buttercups, grass flowers, uncooked white-shelled eggs, small squares of soft cloth, and string. Lay flowers next to eggs, petals spread out. Next, position onion skins on top of flowers. Wrap gently in soft cloth and tie with string. Cook in gently simmering water about 25 minutes. Unwrap cloth, peel off onion skin and flowers, and they are truly beautiful." From Karen Hayes, St. John, WA.

**PRESEVING EGGS:**  Under natural conditions, more hens' eggs are laid during the months of March, April, May, and June than during the other eight months combined. So you tend to have egg shortages from December to January, and an egg glut in April and May. Preserving eggs evens that cycle out somewhat. The eggs you preserve should be the ones that you are most sure are fresh—not over 4 days old, less if possible. Eggs from hens that have no roosters running with them (infertile) will keep longer than fertile eggs. But you can store fertile eggs, too. There are many storage methods. Choose what suits you best.

**About Washing Eggs in the Shell.**  Don't wash any egg that is to be stored in the shell unless you're doing a mineral-oil seal, or unless you follow the instructions below. If the egg is dirty, it's better to just put it into the daily supply to be used up soon. Not washing helps eggs keep, because an eggshell is naturally covered by a gelatinous film, which washing removes. That film helps seal the shell pores. Without it, the egg is more susceptible to bacteria and evaporation. You can assume that a dirty egg is covered with bacteria. A rotten egg is one that bacteria have gotten into. The washing dilemma exists because it is a fact that bacteria can be more likely to get inside the shells if dirty eggs are washed in the wrong way than if the dirt is simply left on there. That is because adding moisture to the dirt will encourage the bacteria to breed and increase; liquid carrying the load of surface bacteria, under certain circumstances, can penetrate through the shell pores into the egg; and washing the "bloom" off the egg removes its outermost shell-pore protecting layer.

**Safely Washing Eggs for Preserving.**  Washing eggs in cold water simply causes them to spoil more quickly. You can make it easy for yourself by simply washing dirty eggs in warm water; use within a week and they'll be fine. Or, first scrape off big chunks of dirt with a table knife. Then prepare your water. It must be at least 20°F warmer than the eggs (minimum 90°F; maximum 120°F). Use a cleaning mixture made of 2 T. detergent plus 4 T. chlorine bleach per 1 gal. water. Use a soft cloth to wipe away dirt. Rinse with clear water that is slightly warmer than the wash water was. Do not wipe eggs dry. Let them air dry in the open on a towel or in a rack.

**Cold Storage.**  The commercial method of preserving eggs is to store them at between 35 and 40°F. At that temperature they'll keep fresh for 100 days. A high humidity is helpful. Don't store eggs near smelly things like kerosene or onions because they easily absorb odors through the shell pores. Old-timers did a sort of cold storage by packing eggs in a barrel or crock (nowadays in a plastic can) in sawdust or oatmeal, small end down, and keeping them in a cool place comparable to cold-storage temperature. For you that could be your refrigerator, root cellar, or basement.

For cold storage, it's best to gather the eggs every day or even several times a day and store them right away in your cool place. A chicken's body temperature is about 107°F. To stay fresh, a freshly laid egg needs to cool to around 60°F reasonably soon. The cooling rate will depend on how soon after being laid you collect the egg, what the air temperature was while it was waiting to be collected, and what you did with the egg after it was collected. Eggs put into egg cartons don't cool quickly because the styrofoam or cardboard is a good insulator. Freshly laid eggs left together in a bucket keep each other warm. In very hot weather you may want to collect eggs at 10am, 1pm, and 5pm. An ideal place to store eggs is a basement or root cellar that is cool and damp and doesn't have much fluctuation in temperature or humidity. Self-defrosting refrigerators are not very good for long-term egg storage because they pull moisture and will gradually dry out fresh eggs. Don't store eggs near where they could pick up strong odors—from onions, chemicals, paints, oil or gas products, and so on. They're most likely to pick up odors if they've been washed. Any poultry eggs can be refrigerated for up to 6 weeks. Always store them in a clean container. Scald it first if there's any doubt. If you seal freshly laid eggs in a plastic bag the eggs can keep in the refrigerator 2 months. When using stored eggs, rotate to use the oldest first.

**Pickled Eggs.**  These come in many varieties. Faking the eggs a few times with a toothpick will help curing (not beet reds—see below). Figure about 7 days to complete curing.
These pickled egg formulas all may be doubled, tripled, etc., as needed. For storage, make in larger quantities and keep in the juice, refrigerated. The pickled eggs will keep months that way. Or you may can them.

**EASY RED PICKLED EGGS** Hard-boil the desired number of eggs. Shell eggs and cover in half pickle juice and half beet juice. Keep in refrigerator 3 to 4 days. Drain and serve with garnish.

**MUSTARD PICKLED EGGS** Boil the eggs, cool, and remove the shells. Boil together 1 qt. vinegar, 1 t. dry mustard, 1 t. salt, and 1 t. pepper. Pour the cooled brine into your pickling jar and add the eggs. Cover and let them cure at least 10 days before they’re ready.

**SPICED PICKLED EGGS** Hard-boil the eggs, cool, and remove shells. Make a brine of ½ c. salt to 2 c. water. Soak the eggs in the brine 2 days. Then pour off the brine and make a new brine by heating 1 qt. vinegar, ¼ c. pickling spices, 2 cloves garlic, and 1 T. sugar to boiling. Pour it over the eggs.

**CLOVE PICKLED EGGS** Stick a few cloves in each egg in either recipe above.

**BEET RED EGGS** Start with 1 c. of strongly colored beet juice, either from canned beets or the homemade equivalent. In a small pan, combine beet juice, 1 c. cider vinegar, ½ c. sugar, and 1 t. salt. Bring to a low boil and hold there for 5 minutes, stirring constantly. Pour over 6 peeled, hard-boiled eggs and refrigerate, tightly covered. Half a serve. You can add a few slices of cooked whole beet to the mixture.

**SOY EGGS** Combine ½ c. soy sauce, ½ c. chicken broth (or water), 6 T. sugar, ½ t. sesame seed oil, and 1 T. minced onion in a pan. Bring to the boiling point. Add 4 peeled, hard-boiled eggs, cover the pan, and simmer 10 minutes. Remove from heat. Allow eggs to cool in the mixture for 30 minutes. Turn the eggs during the cooking and cooling to ensure that they are colored evenly. Drain the eggs and cut into quarters lengthwise to serve (may be served either hot or cold). The beet and soy egg recipes are from Eileen Draper, Pullman, WA—dancer, artist, writer, wife, mother.

**DILL EGG** In a pan combine 1½ c. white vinegar, 1 c. water, 1 t. dill seed, ½ t. white pepper, 3 t. salt, ½ t. mustard seed, ½ t. onion juice, and ½ t. minced garlic. Bring to a slow boil. Boil 5 minutes, stirring frequently. Add peeled, hard-boiled eggs. Cool, cover tightly, and refrigerate.

**CANNED PICKLED EGGS** Fill a sterilized quart jar with hard-boiled, peeled, canned eggs. (You can fit about a dozen eggs in per quart.) Add to the eggs in the jar 1 sprig of dill, I chopped clove of garlic, I dried crushed red hot pepper, and 1 t. peppercorns. In an enamel or other noncorrosive pan combine, for each quart of eggs you are canning, 3 c. white vinegar and 2 T. sugar. Bring the solution to a boil and simmer 5 minutes, then pour hot liquid over eggs and spices to within ⅛ inch of the jar’s top. Put on the lid and seal it. Process in boiling water bath 20 minutes.

**FROZEN EGGS.** The freezer life of an egg is 8 months to a year. Eggs that have been frozen should be well cooked before being eaten. Use only fresh, nest-clean eggs. Don’t ever refreeze thawed eggs. Decide how you will use the eggs: whole, as for scrambling, or yolks and whites separated.

(Frozen whites don’t whip into a stiff mixture.) Or maybe you could use some of each kind. Well, then what percentage of each? Now decide how many of these eggs, whole or separated, you want per package. You have to use your frozen eggs within 12 hours of thawing, so you don’t want to pack more than a day’s worth per package or they will be wasted. Be sure and label each container as to what’s inside: whole eggs, whites, or yolks—and whether the whole and yolks are sweet or salty. Use sweet egg mixtures for baking, salty egg mixtures for other cooking. Be sure and adjust the other ingredients to compensate for the added sweet or salty flavor. Equivalents: 1½ T. thawed yolk equals one fresh egg yolk; 2 T. thawed egg white equals one fresh egg white; 3 T. thawed whole egg equals one fresh egg (sort of, because home-grown eggs aren’t all that standardized anyway).

**Freezing Whole Eggs.** Take them out of the shell and pour them into a freezer container, as many as you decide you want in a package. Stir them together, but don’t whip in air. For each cup of whole eggs, add 1 T. sugar or ½ t. salt. If you freeze whole eggs in an ice cube grid, each cube is equivalent to half an egg.

**Freezing Whites and Yolks Separately.** If you are freezing egg whites, don’t include even a speck of yolk and don’t add anything else. In the case of the egg yolks, freeze them together with either salt or sweetener, depending on the use you intend for them: 2 t. sugar or corn syrup or 1 t. honey, or ½ t. salt per ¼ c. yolks. If you don’t add the salt or sweet to the egg yolks, they’ll get gummy or lumpy. Baby food jars are good containers for them. Freeze egg yolks promptly. They sour easily. When they are thawed, use within 48 hours or discard.

**Brined Eggs.** This was an old-time egg preservation method, but the resulting eggs aren’t as nice as those from cold storage or freezing. Nevertheless, here’s the recipe: Put clean eggs in a crockery, wooden, or plastic container. Cover with a mixture of 3 gal. water, 1 pink quicklime (from lumberyard or drugstore), and 1 c. salt. Put weight enough on top of a plate to hold eggs under the solution. You can add more eggs later, but be careful they don’t crack going in. Store in a cool place.

**Eggs Made into Noodles.** You probably haven’t thought of noodle-making in this way before, but it’s an excellent way to preserve eggs! Use any egg-noodle recipe from Chapter 3 or your own. Make them, dry them thoroughly, and store them in a dry place. Or else package and store them in your freezer. Or make them into a soup and can them.

**Dried Eggs.** Dried eggs won’t keep more than 3–4 months before the yolk fat goes rancid, but up to that time, they can be useful. Ruth Miller found this recipe for dried eggs in a really old recipe book: “Break perfectly fresh eggs onto large plates—making just a layer on the bottom of each; place in the sun to dry. It will take about 5 days to dry them thoroughly so that they break very easily when touched. Then crumble them finely and leave another day. Then roll with a rolling pin to a fine powder and store in clean, dry tins with airtight lids. A good teaspoonful equals 1 egg. The powder should be soaked in cold water or milk for an hour before use and then be used in scrambled eggs, omelets, puddings, cakes, and so on, with perfect success.”

Here’s a modern way to dry them: Beat very fresh, whole eggs thoroughly (use an egg beater or the equivalent). Pour beaten eggs to make a very thin layer (maximum
½ inch) on drying surfaces that have been precoated with plastic or foil. In an oven or dryer, dry at about 120°F for 24–36 hours. When the egg layer is dry on top and firm all through, peel away the plastic or foil layer, turn the egg layer upside down and dry that side 12–24 hours more. Then break it up and dry it a few more hours. Then turn your dried egg into a powder using a mortar and pestle or a blender. These eggs work fine in baked goods. Make scrambled eggs by combining the powder with an equal amount of water, such as ¼ c. dried egg powder with ¼ c. water.

To substitute dried eggs, use 1½ T. dried egg plus 3 T. water for each large fresh egg called for in the recipe. Dried Eggs or Dried Egg Whites are available in a 20-oz. can from UrbanHome@aol.com.

Larded, Salted Eggs. The old-timers used many variations of this method to preserve eggs. The eggs were packed in a crock of lard, or geased with lard or pure butter and then packed in sawdust or oatmeal. They were then stored in the coolest possible place, short of freezing. However, The Mother Earth News experimented and learned that eggs in lard will keep several months even when temperatures are 65–70°F. But cold is always better. An Ohio lady, Yolanda Breidenbaugh, wrote me of “a good, cheap way to preserve eggs. It works wonderfully well. Over a year later the eggs still aren’t rotted. Here it is: Take freshly laid clean eggs and dip them in melted lard and pack in salt! I put them, not touching each other, in a 5-gal. bucket and set the lid on tight. I got ‘feed grade’ salt at the feed store. After 8 weeks, I rinse them off in warm water. After rinse, I store them in a cool cellar. I got a state permit and comply with state laws on food safety and sanitation. For more info: Dept. of Environmental Conservation, Food Safety and Sanitation; 907-289-7501; 555 Cordova St., Anchorage, AK 99501; www.state.ak.us/dec/deh.

Arizona law exempts processors of under 20,000 birds if they are processing according to recognized religious dietary laws; or for personal use; or who label the home-grown and home-butchered product with their name and address before sale to individuals or to restaurants, hotels, or boarding houses: Arizona Dept. of Ag, Meat and Poultry Inspection Branch; 602-542-6398; fax 602-542-4290; 1688 W Adams, Phoenix, AZ 85007.

Arkansas follows federal guidelines as to exemptions: Arkansas Livestock and Poultry Commission, No. 1 Natural Resources Dr., PO Box 1069, Little Rock, AR 72205. Or U. of Arkansas, School of Ag, PO Box 490, Pine Bluff, AR 71611.

California law lets persons who process poultry on their farm be exempt from inspection requirements so long as they sell to persons who are not going to resell the birds: Dept. of Ag, Meat & Poultry Inspection Branch; 916-654-0504; fax 916-654-2608; 150 N St., Room A-125, Sacramento, CA 94814.

Colorado follows federal guidelines in exempting small-scale poultry processors from inspection, but all small-scale processors must have their processing facilities licensed by CDA: Colorado Dept. of Ag; 303-477-0086; fax 303-480-9236; 2331 W 31st Ave., Denver, CO 80211.

Connecticut’s poultry processing is supervised by the Commissioner of Agriculture: 860-713-2500; 860-713-2514; 785 Asylum Ave., Hartford, CT 06105.

Delaware’s Secretary of Agriculture is responsible for poultry inspection. State law is based on the federal guidelines but requires a decision by the Secretary as to any particular exemption: Delaware Dept. of Ag; 302-739-4811; fax 302-697-4463; 2320 S. DuPont Hwy., Dover, DE 19901.

Florida’s Animal and Animal Production Inspection and Labeling Act requires that anybody who processes birds for sale must have federal or state permits: Florida Dept. of Ag and Consumer Services, Division of Food Safety; 850-488-5772; fax 850-487-0703; The Capitol, PL 10, Tallahassee, FL; 32399. Or U. of Florida, Meat Processing Center; 352-392-1921; fax 352-392-7652; PO Box 110910, Gainesville, FL 32611.

Georgia rates as a misdemeanor the offering for sale, or possessing for sale, of any poultry product made, transported, or stored under unsanitary conditions. Their definition of “unsanitary” is very broad. All poultry processing plants must have a license and keep records of all birds slaughtered on site: Georgia Dept. of Ag, Meat Inspection Division; 404-656-3673; fax 404-657-1357; 19 Martin Luther King Jr. Dr., Rm. 108, Atlanta, GA 30334.

Hawaii exempts persons who slaughter poultry for members of their own household and if the product is wholesome and sold at home direct to the consumer (not for resale). Exempt operators must register with the Board of Agriculture and get a permit for exemption (which may be refused): Hawaii Dept. of Ag; 808-973-9560; PO Box 22159, Honolulu, HI 96823-2159. Or U. of Hawaii at Manoa; 808-956-6564; fax 808-956-8663; 1920 Edmondson Rd., Honolulu, HI 96822.

Idaho follows the federal regulations, including exemptions for small-scale processors, and has no state inspection system for poultry processors: Idaho Dept. of Ag; 208-332-8500; fax 208-334-2170; 2270 Old Penitentiary Rd., Boise, ID 83712. Or U. of Idaho, Dept. of Animal & Veterinary Science; 208-885-7390; fax 208-885-6420; Moscow, ID 83844-2330.

Illinois producers may request, in writing, an on-farm processing exemption. If granted (two years at a time), they

Lime/Salt Preserved Eggs. Make a solution containing 16 parts water, 1 part pickling salt, and 2 parts food-grade lime. For example, 1 part could equal 1 cup. Submerge the eggs in that. The Mother Earth News tested this one and found it also would preserve eggs several months, even at 65–70°F.

Laws on Home Poultry Processing

Under federal law, there is no inspection if you process fewer than 20,000 chickens (or 5,000 turkeys) per year (Poultry Products Inspection Act, Section 15), so long as the poultry is sold in your state. Local and state regulations may be more restrictive. Here follows a summary of the laws in each state, inspired by and indebted to "Legal Issues for Small-scale Poultry Processors," compiled by Janie Hipp for Heifer Project International. (It’s free from NCAT/ATTRA: 800-346-9140; www.attra.ncat.org).

Alabama has a state law controlling meat and poultry inspection, administered by the Commissioner of Agriculture and Industries: Meat and Poultry Inspection; 334-240-7210; fax 334-223-7352; 1445 Federal Dr., PO Box 3336, Montgomery, AL 36109-0336.

Alaska’s small-scale poultry processors may need to get a state permit and comply with state laws on food safety and sanitation. For more info: Dept. of Environmental Conservation, Food Safety and Sanitation; 907-289-7501; 555 Cordova St., Anchorage, AK 99501; www.state.ak.us/dec/deh.

Arizona law exempts processors of under 20,000 birds if they are processing according to recognized religious dietary laws; or for personal use; or who label the

The Mother Earth News
must keep records of the number of poultry processed per year (no more than 5,000 to keep the exemption). They must sell only from the farm (no deliveries), and must be sanitary (periodic inspections may occur): Illinois Dept. of Ag; 217-782-2172; fax 217-785-4505; State Fairgrounds, PO Box 19281, Springfield, IL 62794.

**Indiana** State Board of Animal Health, under the Indiana Humane Slaughter Act, is required by law to exempt a processor who would be exempt under the federal guidelines: Commissioner of Ag; 317-232-8770; fax 317-232-1362; 140 W Market St., Ste. 414, Indianapolis, IN 46204. Or Indiana State Board of Animal Health, Division of Meat & Poultry; 317-227-0359; fax 317-227-0330; 805 Beachway Dr., Ste. 50, Indianapolis, IN 46224.

**Iowa** poultry inspection is under the Meat and Poultry Inspection Bureau, which exempts processors who handle fewer than 1,000 birds per year and sell all products to the final consumer or use them at home: Iowa Dept. of Ag & Land Stewardship; 515-281-5322; fax 515-281-6236 (or 515-281-5597; fax 515-281-4282); Wallace Bldg., Des Moines, IA 50319.

**Kansas** exempts poultry producers who slaughter for home use and under certain other conditions: Kansas Dept of Ag, Meat & Poultry Inspection; 785-296-3511; fax 785-296-0673; 901 S. Kansas Ave., 7th Floor, Topeka, KS 66612.

**Kentucky** producers must follow rules of the Kentucky Cabinet for Health Services: Kentucky Dept. of Ag; 502-564-5126; fax 502-564-5016; Room 188, Capitol Annex, Frankfort, KY 40601. Or Market Services Office; 502-564-4696; 502-582-4291; Capital Plaza Tower, 7th Floor, 500 Mero St., Frankfort, KY 40601. Or Benjy Mikel; 859-257-7550; 205 WT, Garrigus Bldg., U. of Kentucky, Lexington, KY 40546.

**Louisiana** Dept. of Ag and Forestry's Meat and Poultry Division does inspections for operations of fewer than 20,000 birds and grants exemptions upon written request of the processor (quarterly compliance checks on persons with exemptions): Dept. of Ag & Forestry; 225-922-1234; fax 225-922-1253; PO Box 631, Baton Rouge, LA 70821-0631.

**Maine** established new guidelines in 2002 that are said to be friendly to small-scale producers and processors: Commissioner of Agriculture, Food and Rural Resources; 207-287-3419; fax 207-287-7548; Deering Bldg (AMHI), State House Station #28, Augusta, ME 04333. Or U. of Maine; 207-581-3449; fax 207-581-3212; 5717 Corbett Hall, Rm 303, Orono, ME 04469.

**Maryland** exempts from inspection any poultry processed for home use, or for sale from your home if healthy and labeled with your name and address: Maryland Dept. of Ag; 410-841-5880; fax 410-841-5914; 50 Harry S. Truman Parkway, Annapolis, MD 21401. Or U. of Maryland College of Ag; 410-651-9111; fax 410-651-9187; LES/REC, Princess Anne Fac., 11990 Strickland Dr., Princess Anne, MD 21853.

**Massachusetts** exempts poultry processors from inspection at the discretion of its Commissioner of the Massachusetts Dept. of Public Health, so long as exemptions fit under federal guidelines. Thus the processor must be selling birds he raised himself. They must be shipped in boxes that bear the grower's name, address, and the word "Exempted." He may sell to households, restaurants, hotels, and boarding houses: Mass. Dept. of Ag; 617-626-1700; fax 617-626-1850; 100 Cambridge St., Boston, MA 02202.

**Michigan** uses the federal guidelines: Michigan Dept. of Ag; 517-373-1052; fax 517-335-1423 (517-373-8200; fax 517-373-6015); 611 W. Ottawa, PO Box 30017, Lansing, MI 48909.

**Minnesota** also follows federal guidelines except that direct farm sales are allowed only to households (not to hotels, restaurants, and institutions). To deliver products off farm or sell them at a farmer's market you must get a state license and comply with state inspection rules, no matter how few the birds being processed: Minnesota Dept. of Ag; 651-296-2627; fax 651-297-5637; 90 W. Plato Blvd., St. Paul, MN 55107.

**Mississippi** follows federal guidelines: Dept. of Ag and Commerce; 601-359-1100; fax 601-354-6290; 121 N. Jefferson St., Jackson, MS 39201. Or Meat Inspection Division; 601-359-1189; fax 601-354-6502; PO Box 1609, Jackson, MS 39215.

**Missouri** must exempt from inspection laws any facility that would be exempt under federal guidelines, but persons with such exemptions are subject to regular reviews. The Director of the Missouri Dept. of Ag is allowed, after giving notice, to withdraw any exemption if conditions have changed under which it was granted: Missouri Dept. of Ag; 573-751-3359; fax 573-751-1784; PO Box 630, Jefferson City, MO 65102.

**Montana** Board of Livestock (under Montana's Dept. of Livestock) does poultry inspection. Persons slaughtering for home use are exempt. Custom butchers are exempt so long as the meat is kept separate from meat prepared for sale, is plainly marked "Not for Sale," and is handled in a sanitary way: Montana Dept. of Ag; 406-444-3144; fax 406-444-5409; PO Box 202021, Helena, MT 59620-0201. Or Meat, Milk & Eggs Inspection Division; 406-444-5293; fax 406-444-1929; PO Box 2021001, Helena, MT 59620.

**Nebraska** follows the federal guidelines: Bureau of Dairies & Foods; 402-471-2536; fax 402-471-2759; PO Box 95064, Lincoln, NE 68509.

**Nevada** State Board of Health does not permit the sale of uninspected poultry products. Federal exemptions don't apply here. Anybody who wants to process and sell poultry must have a state permit. The permitting process requires inspection of your place by the state Board of Health and that there be an inspector present when birds are processed. However, owner/operators may be tested and certified as inspector at their own place: Nevada State Board of Health; 775-687-6353; fax 775-687-5197, 1179 Fairview Dr., Carson City, NV 89701. Or Nevada Dept of Ag; 775-688-1182; fax 775-688-1178; 350 Capitol Hill Ave., Reno, NV 89502.

**New Hampshire** policy follows the federal guidelines: New Hampshire Dept. of Ag, Markets and Food; 603-271-3551; fax 603-271-1109; PO Box 2042, Concord, NH 03302-2042. Or U. of New Hampshire, Cooperative Ext. Food Safety & Nutrition; 603-862-2496; fax 603-862-3758; 129 Main St., 219 Kendall Hall, Durham, NH 03824.

**New Jersey** allows uninspected processing of home-grown birds for home use: NJ Dept. of Ag; 609-292-3976; fax 609-292-3978; PO Box 330, John Fitch Plaza, Trenton, NJ 08625. Or Rutgers U., Dept of Food Science; 732-932-9611; fax 732-932-6776; 65 Dudley Rd, New Brunswick, NJ 08901.
New Mexico does not allow any exemption from inspection for poultry slaughtered on the farm: New Mexico Livestock Board; 505-841-6161; fax 505-841-6160; 300 San Mateo NE, Ste. 1000, Albuquerque, NM 87018.

New York exempts by federal rules up to 1,000 birds per year: NY Dept. of Ag and Markets; 518-457-4188; fax 518-457-3087; 1 Winners Circle, Capitol Plaza, Albany, NY 12235. Or Cornell U., Dept. of Food Science; 607-255-3262; fax 607-254-4868; 11 Stocking Hall, Ithaca, NY 14853.

North Carolina's Dept. of Ag and Consumer Services inspects poultry products. Exemptions are given for processors of less than 1,000 birds or 250 turkeys; or those operating according to religious dietary laws; or if the birds are home grown for home eating; or custom slaughter of birds intended for the customer's home use. Small growers may process and sell their home-grown healthy poultry if packaged under a label identifying the name and address of the producer. They may sell to households or distribute to restaurants, hotels, and boarding houses: Dept. of Ag and Consumer Services; 919-733-7125; fax 919-733-1141; PO Box 27647, Raleigh, NC 27611. Or Meat and Poultry Division; 919-733-4136; fax 919-715-0246.

North Dakota's Health Dept. gives no exemptions from inspection requirements for farm-slaughtered poultry: ND Dept of Health; 701-328-2213; fax 701-328-4567; 600 East Blvd., Bismarck, ND 58505-0020. Or ND State U.; 701-231-7682; fax 701-231-7590; 5727 Hultz Hall, Fargo, ND 58105.

Ohio exempts growers processing for family use, and grower-processors of fewer than 1,000 birds per year who sell to other household consumers (no resale expected). You are still subject to laws on licensing, sanitation, labeling, etc.: Ohio Dept. of Ag; 614-466-2732; fax 614-466-6124; 8995 E. Main St., Reynoldsburg, OH 43068-3399. Or Division of Meat Inspection; 614-728-6260; fax 614-728-6434.

Oklahoma allows certain exceptions for small producers or religious processing, etc.: OK Dept. of Ag; 405-521-3864; fax 405-521-0909; 2800 N. Lincoln, Oklahoma City, OK 73105. Or Meat Inspection Program; 405-521-3741; fax 405-522-0756.

Oregon follows federal guidelines. Inspection is also not applied to fries that are sold to ultimate customers at the farm where they were produced: Oregon Dept. of Agriculture; 503-986-4552; fax 503-986-4750; 635 Capitol St. NE, Salem, OR 97310-0110. Or Oregon State U.; 541-737-3414; fax 541-737-4174; Withycombe Hall 112, Corvallis, OR 97331.

Pennsylvania's Dept. of Ag and various municipal departments can enact and enforce regulations: Dept. of Ag; 717-772-2853; fax 717-772-2780; 2301 N. Cameron St., Harrisburg, PA 17110-9408. Or Bureau of Food Safety & Lab Services; 717-787-4315; fax 717-787-1873; 2301 N. Cameron St., Harrisburg, PA 17110.

Rhode Island poultry growers who do their own processing for either home use or sale must register each year with the Director of the Department of Health during the month of January. Slaughter premises must be approved by the Department, and the Director of the Department can make rules about those premises and can inspect them as he wishes: RI Dept. of Ag; 401-222-2781; fax 401-222-6047; 235 Promenade St., Room 370, Providence, RI 02908-5767. Or ESN Research Center: 401-874-2972; fax 401-874-2994; 530 Liberty Lane, West Kingston, RI 02892.

South Carolina allows exemptions from getting a permit to persons who butcher according to religious dietary laws; persons processing home-grown poultry for home use or doing custom slaughter on somebody's home-grown birds for home use; persons selling to households, restaurants, hotels, or boarding houses home-grown poultry that have been raised healthy and are labeled with the grower's name and address (up to 20,000 birds or 5,000 turkeys): SC Meat & Poultry Inspection Division; 803-788-1747; fax 803-788-8114; PO Box 102406, Columbia, SC 29224-2406. Or Clemson U., Meat & Poultry Inspection: 803-788-2260.

South Dakota's Livestock Sanitary Board runs their inspection program and allows no exemptions from inspection: SD Dept. of Ag; 605-773-3375; fax 605-773-5926; 523 E. Capitol, Pierre, SD 57501-3182. Or SD Animal Industry Board; 605-773-3321; fax 605-773-5459; 411 S. Fort St, Pierre, SD 57501.

Tennessee's Meat and Poultry Inspection Act is administered by their Dept. of Ag. Growers report that the rules are confusing, unevenly applied, and not always administered according to the written law: TN Dept of Ag, Ellington Ag Center; 615-837-5100; fax 615-837-5333; PO Box 40627, Melrose Station, Nashville, TN 37204.

Texas accepts the federal guidelines and exempts small-scale processors from inspection. However, low-volume livestock processing establishments must register with the Texas Dept. of Health (TDH) and must develop a Sanitary Operations Procedures Plan that you keep on file for government review in case anybody gets sick from your animals. If anybody does get sick, they may shut you down: TX Dept. of Ag; 512-463-7476; fax 512-463-1104; PO Box 12847, Capitol Station, Austin, TX 78711. Or Meat Safety Assurance Division, Bureau of Food and Drug Safety; 512-719-0205; fax 512-810-0240; 1100 W 49th St., Austin, TX 78756.

Utah follows federal guidelines: UT Dept. of Ag and Food; 801-538-7101; fax 801-538-7126; 350 N. Redwood Rd, PO Box 146500, Salt Lake City, UT 84114-6500. Or UT Dept of Ag; 801-538-7117; fax 801-538-7169; PO Box 146500, Salt Lake City, UT 84114-6500.

Vermont Commissioner of the Dept. of Ag, Food and Markets may exempt from inspection any person who could be exempted under the federal guidelines. But Vermont's rules are more strict than federal ones, applying only to processors of up to 1,000 birds. Any meat served in hotels, restaurants, or institutions must be from a state or federally inspected source: VT Dept of Ag, Food and Markets; 802-828-2426; fax 802-828-2361; Drawer 20, 116 State St., Montpelier, VT 05620-2901.

Virginia law follows the federal guidelines, but the state does require producers who want to operate under exemption to get a state permit: VA Dept. of Ag and Consumer Services; 804-786-3501; fax 804-371-2945; PO Box 1163, Richmond, VA 23209.

Washington's Dept. of Agriculture is in charge of inspections. Slaughter of birds by religious dietary laws or for home use is exempted. Inspection is unnecessary for poultry growers if they are under 250 turkeys or 1,000 birds of smaller species per year. But some city and county agencies have additional rules and do not recognize these exemptions (King County/Seattle area requires all poultry sold therein to be processed and stored in a state-licensed facility); WA Dept. of Ag; 360-902-1801; fax 360-902-2092;
Butchering Chickens

Once you know what you’re doing and have your system worked out, 2 people can kill, pick, and cut up about a half dozen chickens an hour—or even more.

Of Age and Stage: Home-grown chicken to eat comes from 2 basic sources: the broilers or cockerels you raise to butchering age and then put in the freezer, and the hens whose egg production is declining or stopped, that you cull out of your flock. The broilers or cockerels are your young, tender birds. At 8-12 weeks of age, they’ll weigh from 2 to 8 (or 12 or even 15) pounds, depending on your young, tender birds. At 8-12 weeks of age, they’ll weigh from 2 to 8 (or 12 or even 15) pounds, depending on the breed. They can be cooked as a “broiler,” or a fryer. From 14 weeks to 6 months of age, and from 4 pounds and up, the bird will make a fine roaster. If you want to know something similar, you won’t have to contend with such a full crop when cleaning it.

Catching a Chicken at Night: If the chicken can’t be walked up to when you feed it (or cornered in the chicken house), make a chicken hook out of a length of wire. Unwinding a clothes hanger gives you a good length. Or use a 4-foot piece of heavy wire. Make it single rod except for a miniature shepherd’s crook at the chicken-catching end—narrower than a chicken’s foot, wider than its skinny lower leg, which is the part you hook it by. Or loop around the other end to make a better handle. Then you set out to pursue your quarry with the wire in hand. Pour a heap of grain on the ground. The chickens will all gather, heads down, backsides to the outside of their little crowd.

When you get within reach of the one you want with the wire, suddenly stretch it out and hook the chicken’s leg in the crook. Pull the chicken toward you and transfer the leg from the crook to your hand and get the other one, too. That works, but it’s so much easier to catch a chicken while it is sleeping that I always do that. And if you can isolate the chicken the night before you butcher it, by leaving it in theunny sack or, better yet, in a wire-bottomed rabbit cage or something similar, you won’t have to contend with such a full crop when cleaning it.

Meat Chickens to Sell: Joel Salatin’s 1993 book, Pastured Poultry Profit, is the classic in this field. Herman Beck-Chenoweth’s Free-Range Poultry Production and Marketing (1996) shows a set-up to process 200 broilers per hour (cost about $15,000).

New poultry processing equipment is available from Stromberg’s (218-587-2222) or Pickwick (319-393-7443; www.pickwickmfg.com), or Brower’s Pastured Poultry Division, which advertises a 150 birds/hr system for under $4,000 with rotary kill line, scalders, pin picker, evisceration table, chill tank, aprons, knives, etc. (800-553-1791). You can buy used equipment from Tom Neuberger’s South Dakota Poultry Headquarters: 605-296-3314; Rt. 1, Box 303, Canistota, SD 57012. Contact ATTRA for info on homemade scalders and pluckers: 800-346-9140. Kenneth King of Jako, Inc., builds a low-cost batch dunker/scalder, and plucker. He travels to help other area producers on slaughter day with a mobile processor mounted on a trailer (killing cones, scalders, plucker, eviscerating table, etc.), which he also builds and markets: 620-663-1470; 877-525-6462; 6003 E. Eales Rd., Hutchinson, KS 67501; kenking@jakoinc.com; www.jakoinc.com/.

Some producers have built their own state- or federally approved processing plants. (See Patrick Slattery’s “Small-scale Processing Offers Large-scale Profits” in Acres, USA, Sept. 1995; or Keith Richards’ article on “Adding Value to Chickens on the Farm,” in Southern Sustainable Farming, March 1996.) ATTRA’s info on this topic, “Processing & Marketing Chicken Products: Meat & Eggs,” can be downloaded at www.attra.org/attra-pub/process&market.html.

Killing a Chicken: When I was a little girl, chopping chicken heads off for my mama, I used to say a prayer for the chicken before I raised my axe. I would pray that if God had a place in Heaven for the souls of chickens, He should please take this one. In the animal graveyard beside our garden, where beloved, departed cats, dogs, and mice lay planted, brother Dick and I also buried not a few chicken heads with full honors. There was a certain fascination to staging a really good funeral.
By then the feast would be ready, and Mama would call us to dinner. Oh, Mother's fresh fried chicken! With mashed potatoes and lots of gravy made with milk! Dick and I would eat and eat, the pile of bird bones beside each plate heaping steadily. The wishbones were saved and dried on top of the topside cupboard of Mother's wood cook stove for a week or two, until they'd become properly brittle. Then Dick and I each took hold of a side, got our wish in mind (you couldn't say out loud what it was or the magic wouldn't work), and pulled at the count of three. The one who ended up with the longest piece of wishbone would get his or her wish—or so we claimed.

"Chop and run" is how I killed chickens for Mama and how I did it when I was writing the first edition of this book, but it's not the best way because it's messy. These following methods are approximately in order from worst to best because that's the order in which I heard about them as I accumulated material for this book. To avoid gory details you could just skip to the end of the list. But first read this next paragraph.

**Blood.** However you get the unfortunate task accomplished, be sure and let the bird bleed out thoroughly, since this will improve its eating and keeping quality. Wear old clothes, have a container ready—a bucket or some such—and don't let go of the chicken's legs and wing tips after the head is severed. Then get the chicken neck down into that container as soon as possible to minimize the mess. If you just drop the bleeding body and run, it will flop around, scattering blood from the severed neck over an amazingly large area.

**A Chopping Block Demise.** You grasp the bird firmly by the ankles and both wing tips with the left hand (assuming you're right-handed), and place its body on the chopping block so that the neck is stretched out across the block. (A chopping block is a large flat-topped and flat-bottomed piece of tree, with the grain running perpendicular to the ground.) A heavy-headed ax is better than a hatchet for the job, I think.

Getting the chicken to lie still with its neck stretched out across the top of the block while you aim the blade may require a bit of maneuvering. The chicken may retract its head just when you're all set. [Note: Since I wrote that, I've gotten some interesting advice from readers on how to make that chicken hold still while you're trying to chop its head off. One writer told me that she "hypnotizes" the chicken by putting the chicken's head under its wing, then swinging it around, and only then chopping its head off. Betty Lawrence, White Swan, WA, wrote me that she hammers 2 nails about one inch apart on the surface of her chopping block. She leaves part of the nails sticking up. She lays the chicken's neck between the nails and pulls back gently until the head is next to the nails. If you use this system, you'll have to be careful not to hit those nails—hitting nails is very bad for ax blades—as well as not to hit the crop.]

Anyway, have a sharpened ax or hatchet ready in your right hand for that moment when the bird is in the right position, and then, quick before it moves, with one hard blow bring the blade down and sever the head from the neck. Hit the chicken's neck clear across so you don't cut off just half of it with the first blow. (I've had to try twice to finish the job more times than I'd care to admit.) Cut it off as near the head and as far from the body as you can in order to save the neck for cooking, and to avoid cutting the crop, which is located at the base of the neck.

**Wringing the Chicken's Neck.** Some people prefer this method. It may be done by grasping the chicken firmly by the upper part of the neck or head. Then get the body swinging rapidly as you would twist a heavy object on the end of a string. You swing once, swing twice, swing thrice, and then snap—like you're doing "Crack the Whip" with the chicken's body. Then the body separates from the head you're holding. It will.

**Death by Shooting.** A BB-gun won't do it. A .22 will.

By "Hanging." Mrs. George Huckabey, Athens, TN, doesn't like dead chickens flopping around on the ground. "Find a low-hanging tree branch; loop a twine string around it firmly. Place loop around the legs of the chicken. It will be hanging head down. Now grasp the head firmly and with a sharp knife, cut the chicken's head off just at the top of the neck." This way the chicken doesn't go flopping around, leaving a trail of blood on your property, and you can control the bleeding mess by having a container ready to put the bird in and making sure it gets in there and stays in there. Lane Morgan uses this system too.

**By Severance.** This popular professional method is to pierce the brain with a knife turn through the roof of the mouth, then Sever the blood vessels, which are in the neck behind the earlobe. With this method, the bird doesn't flop about either, but it takes some know-how and experience to get it right.

**Killing Cone.** You can mail-order a commercially produced killing cone from a poultry supplier or from a local farm-supply store or make your own. To make a homemade killing cone, cut off the bottom of a 1-gal. plastic bottle. Cut about 2 inches from the top and handle. Nail the bottle to a wall or tree—or hang it by a rope or hook upside down. To use the killing cone, grab your bird by the ankles and put it, head downward, into the killing cone. Make sure the head and neck extend through the smaller end that you cut. Now proceed with either the "hanging" method or the "severance" method, or by grasping the head with one hand and pulling just firmly enough to create a small amount of tension on the neck, then cut into the neck on the left underside, just back of head and beak—which will sever the jugular. When you do it the latter way the head stays on; you just cut the throat. Have something ready in which to
catch the blood, and this is the most manageable and least messy way. Commercially manufactured killing cones are not expensive and come in 3 sizes: one for broilers, pheasants, and fryers; one for roosters, ducks, and guineas; and the largest for turkeys.

**Hiring Out.** Lane Morgan wrote that "lots of communities have backyard chicken butchering entrepreneurs. You bring them live birds in the evening and pick up dressed, bagged, chilled chicken the next morning. Or sometimes they'll come to your place. Or you can rent their equipment and have a butchering bee with friends. When both partners work off the farm, which is more and more likely, it's not easy to find a solid stretch of time to butcher 50 chickens with less-than-efficient equipment."

**Picking the Chicken:** There are those who just skin the bird. In that case there's no scalding, no plucking, no disagreeable wet feather smell, no singecing. If you have no use for the feathers and remove the skin anyway to keep the fat low, this may be your best choice. Otherwise, following tradition...

You need to choose between dry picking and scalding before plucking out the feathers. Dry picking is more difficult than picking after scalding, because the feathers are harder to pull out. I think it's crazy to dry pick when you could scald. So skip to the next paragraph. But then again, maybe you want the feathers. But you can use the feathers plucked from a scalded bird, too. But connoisseurs say they prefer feathers that have been dry-picked rather than scalded and then picked.

**Dry Picking.** If you're going to save the feathers, have bags ready. Start immediately after killing—even before the bird stops bleeding—before the flesh has a chance to become cold, which will set the feathers in tightly. Pick up the breast and up the side. Then do the wings, back, and finally the pinfeathers, which can be removed with tweezers or with a knife blade (you catch the pinfeathers between the blade and your thumb and pull). You'll clean the feathers later and make them into nice things. Right now you need to get on with the butchering. Go to "Singeing."

**Scalding and Plucking.** Put water in a metal bucket or a big pan (like a canner or roaster) on to boil before you go to the picking. Make sure you get the legs that you're holding in far enough to scald the feathered "knees." Make sure the wing and tail feathers get a good scalding, because they are the toughest to pull out. Overscalding any part of the bird will cause the outer surface of the skin to rub off—which doesn't hurt the meat any. Less than 30 seconds should to it. Hotter water does the job quicker; with cooler water you'll have to keep the bird in there a bit longer.

How long you need to scald also depends a good bit on the size of the bird. Little birds like pigeons and quail need less scalding time. Bigger birds need more. A turkey requires the most of all. Older birds will take a higher temperature and a longer time than younger birds. You can scald several birds, one after the other, in the same water, so long as it doesn't cool below about 130°F. If your water gets too cool, add hotter water to bring it up. If the first dip doesn't loosen the feathers enough, you can give the bird another pass in the water. You have to have the bird in there long enough and with enough motion to get the hot water penetrated clear to the skin.

Then take the bird out, let it drain just long enough so you can get your hands on the biggest feathers and start yanking. Have newspapers or some such spread out to pick the bird on so that cleaning up will be easy—but don't let the bird's body actually contact the newspaper because you don't want lead in your diet (causes brain damage). It can help with the requirement to do the picking while the bird is still as hot as possible, if one person scalds and another picks. Commence picking immediately after pulling the fully soaked bird out of the hot water, starting with the wing and tail feathers. Then do the body feathers, and finally the pinfeathers. Purists insist that feathers must be pulled out in the direction in which they are growing. That's certainly true of the biggest ones. I pull short ones any way I can get them.

**Singeing.** After the pinfeathers have been removed, you will still have down and very fine long hairs, especially on an older bird. These are burned off by singeuling. Do it someplace where you won't set anything else on fire. Hold your bird by the ankles over a flame. If you don't have a gas stove, you can use a candle, propane torch, small alcohol burner, or a rolled cone of newspaper or other paper (not with color)—rolled tight at one end (to be the handle), and wide enough at the other to flame readily. A burning paper bag won't blacken the bird as much as a newspaper, but a newspaper cone is probably actually the worst way—probably gives them a lead content or some such and it certainly risks setting something else on fire. Don't touch the paper to the bird in this process, since that would dirty it with ashes. With practice you can do several chickens with one paper cone. Have all the chickens you plan to singe right there at hand when you light the paper. That's the way my mother and I used to singe them. Constantly change the bird's position over the flame, holding the bird with one hand and the cone with the other, until all parts having these hairs have been exposed enough to singe them completely. It won't take long to singe the whole chicken.

**Cleaning the Chicken:** Now your chicken is ready to be cleaned or "drawn." That means you'll remove the head, feet, and innards. First, put the bird into very cold water in order to cool the entire body quickly. Get ready a bowl of clean, cold water to rinse pieces in (or you can rinse them under the faucet), a very sharp knife, and an
empty container to hold the cut-up pieces. Have ready a wooden cutting board to cut up the chicken on. Don’t cut the chicken on newspaper because the ink could get on the meat. Have something ready to hold the disposables, like a wax-paper-lined box, or a bucket.

You can dispose of innards by burning, composting (but not where varmints will scatter the compost pile), or feeding them to the pigs. Your chickens would be delighted to recycle the chicken butchering scraps—if you have no fear of parasite or disease transmission. Do not feed these raw chicken scraps or any other poultry innards to your dogs and cats, lest they become tempted to obtain more of the same by killing a few birds for themselves.

Poultry Tuberculosis (TB). Incidentally, there is a variety of TB that chickens can get. The older the bird, the more likely it is to have this—or any other problem. On the other hand, I’ve never had TB in a flock and most family flocks never do. But if you do, the bird would feel very light, wasted, and the innards would look weird, would have abscesses on them (bird TB attacks the digestive tract and their intestines get abscesses on them). If you suspect TB, don’t eat the bird.

Head, Feet, and Oil Sac. You need a small, but very sharp knife to do the next steps. If the head is still attached, cut it off and discard. If the head was chopped off and the chicken flopped on the ground and got dirt on the stump, cut the dirty part off and discard. Carefully feel for the knee joint right at the top of where scaly leg meets feathered knee. Bend the knee and cut across each joint until the foot is off. Some authors tell you to cut off the small oil sac at the end of the chicken’s back on the “north end going south.” That isn’t necessary. Its presence doesn’t affect the taste. It is necessary with certain other birds (goose and duck and game birds).

Outing the Innards. Place the chicken on its back with its hind end closest to you. Carefully cut across the abdomen from thigh to thigh (or from below the breastbone to just above the anus—it doesn’t matter which), making sure you do not cut into any of the intestines in the cavity. Reach inside carefully between the intestines and the breastbone until you reach heart level. Loosen the membranes between the innards and the body wall and gently pull out the entrails in one mass. The gizzard, heart, and liver will come out with it. Be especially careful of the gallbladder, a greenish sac embedded in the undersurface of the right lobe of the liver. If it should break, the bile that it contains will make bitter and undesirable any part of the chicken that it touches. You’ll probably have to make a special effort to scoop out with your fingers the light pink lungs, which adhere inside the ribs.

To finish extricating the innards, cut carefully around the outside of the excretory vent, allowing plenty of room so as not to cut into it or the attached intestine, so that it can now be discarded along with the intestines. The kidneys in the back cavity adhere closely and should now be at least partly removed. Just scoop out what you can with your fingers of the soft, brown kidney tissue. It’s impossible to get all the kidney out. Don’t worry about what’s left. It will be cooked along with the rest of the bird. Now, finish up the front end of the chicken: cut the skin the length of the back of the bird’s neck. The crop tears very easily. The crop is a thin-skinned round pouch off the bird’s esophagus that serves as a first stomach. You must gently pull it apart from the skin next to it. Then carefully pull crop, esophagus, and windpipe out of the bird and discard them.

Removing Giblets. “Giblets” means heart, liver, and gizzard—usually the neck, also. To get the liver, cut off the part of it that contains the gallbladder—allow plenty of leeway (better safe than sorry), and discard the gallbladder along with its attached liver section. Rinse the remaining liver and put it into your giblets bowl. Cut the gizzard open along its narrow edge. Continue the cut to three-quarters of the way around. Inside the gizzard there will be food and grit. Empty that out onto your newspaper. Carefully peel off and discard the yellowish inner lining of the gizzard. If you can get that lining separated from the gizzard proper at some point along your cut edge, the rest of the lining should strip out, easily connected to it. If it tears and does not all come out the first time, you’ll have to work it loose at some other point, then pull again. When the lining is all pulled off, discard it. Rinse and save the gizzard. Cut the heart away from its attached arteries, rinse, and put in your giblet bowl. Cut the neck off at the base and add it to your loose pieces in the bowl.

Outing the Innards: Poultry Shears Method. An alternative system popular with owners who must butcher many small birds (like game birds), duck owners, and efficiency lovers in general, is to cut off the oil-gland on the bird’s tail, then carefully cut around the vent until the anus and attached intestine are separated from the rest of the bird, and then use the poultry shears to cut all the way up the back on one side of the backbone. The bird is then opened out from that cut and the innards will basically just drop out. Sort out and deal with heart, liver, gizzard, and neck as above. (Poultry shears are wonderful. You can also use them to simply halve and quarter the bird and be done with the cutting up process, too!)

Dealing with the Garbage. At this point you have feathers and innards. You can make use of the small feathers (see “Cleaning and Using Feathers”). Or you can bury the whole works in your compost bin. Make sure no creatures can dig it up again.

Washing the Bird? June Scherer, Eastman, WI, wrote me that she washes and scrubs the chicken’s skin with dish soap at this point. “It’s surprising how dirty they are, and the soap leaves no taste. Just rinse good.”
Marketing Your Poultry. You could go into the poultry business. Lane Morgan wrote me, “People (at least city people) will pay a lot for humanely raised, nonmedicated poultry.” She’s right. I have a cousin who does well taking orders for broilers. She merely grows them and then contracts out the butchering. Takes only prepaid orders. She charges $8 per bird [1992]. Many families order their year’s supply of chicken from her and then store it in their deep freeze to eat year-round. It’s true that there is an amazing, clearly discernible difference in the taste of “real” chicken like hers and factory-produced supermarket chicken. And she, as Lane Morgan suggests, can indeed guarantee her customers that her chickens’ lives, though short, are pleasant, and that they bear no antibiotic or other chemical residue. She never has advertised. She got started because people asked her to and her business has grown by word of mouth.

A reader in Missoula, MT, became a serious chicken rancher in a similar way: “I sell 100 chickens every 7 weeks. There is a large population of Hmong [Vietnamese] people in Missoula. One day this teacher friend called to ask if I had any chickens to sell. At the time, my husband and I annually raised fifty chickens for ourselves and fifty to sell. Joan asked me if she could tell her Hmong friends about my chickens and I willingly agreed. I remember Joan saying, ‘You may have a lot of people coming out.’ That turned out to be the supreme understatement.

“The next morning we started getting calls at 8am. It didn’t stop all day. Whole families came out. Usually only one person in the group had English. It was wild. When all the chickens were sold, except for ours, the people still came. They insisted that we had too many chickens. Please, sell only 3 more! . . . In the end we had only 25 for ourselves. Still more Hmong people came. They pointed to my chicken house where my laying flock lives. When I told them that I had no more chickens to sell, they said, ‘Yes, you have many chickens. You sell me some!’ I’d say, ‘No, those are my layers.’ They’d say, ‘You sell me 3 layers!’ Then a young man came who had excellent English. I explained the situation to him, and we came to an agreement. My husband built a brooder house in which I can raise chicks. When the chickens were sold, except for ours, the people still came. They insisted that we had too many chickens. Please, sell only 3 more! . . . In the end we had only 25 for ourselves. Still more Hmong people came. They pointed to my chicken house where my laying flock lives. When I told them that I had no more chickens to sell, they said, ‘Yes, you have many chickens. You sell me some!’ I’d say, ‘No, those are my layers.’ They’d say, ‘You sell me 3 layers!’ Then a young man came who had excellent English. I explained the situation to him, and we came to an agreement. My husband built a brooder house in which I can raise chicks all year. The Hmong would buy even more than what I have now, but one hundred at a time is all I care to manage.”

Killing, plucking, cleaning, and singeing is not an issue at all for the above writer. She told me that one of the big reasons the Hmong were so eager to buy live chickens from her is because it’s a matter of conviction with them to do their own butchering! But if you’re willing to butcher as well as grow the birds, there are exemptions for small producers in the Poultry Products Inspection Act. Check with your state Department of Agriculture for more information.

Making Use of Unusual Chicken Parts

Cooking Giblets. If your bird is a roaster, you can use the giblets (except for the liver) in the stuffing or gravy. (Precook and dice them, then mix them in.) If your bird is to be a fryer, fry the giblets right along with the rest of the pieces. If it’s a stew bird, use the giblets (except the liver) right with the rest. Another way to use giblets is to grind them up for taco and pizza meat. When chicken is canned, the hearts and gizzards are canned separately, and the livers are not canned at all.

FRIED LIVERS AND HEARTS Sift together 1 c. flour, ½ t. salt, and ½ t. baking powder. Add enough water so you have a thin batter. Dip the separate hearts and livers one by one into it. Then fry them in hot (350°F), deep fat until the batter changes color to a golden brown. Remove from fat, drain off excess fat, and serve.

About Bird Livers and Pâté. The liver gets left out of most recipes because its flavor is just too distinctive to blend successfully. From extra livers you can make the gourmet delicacy called pâté. The livers of about 5 or 6 average-sized chickens will give you ½ lb. of chicken livers. If you just do in a couple every Saturday for Sunday dinner, you could add the fresh livers to your supply in the freezer until you have enough to make pâté. You can make pâté out of any bird livers; recipes are by weight of liver, and variety of bird doesn’t matter. If you have a food processor or blender, that helps to get the pâté perfectly smooth. After the pâté is made, it’s stored in a small crock or bowl in the refrigerator. Old-timers kept the vulnerable pâté from contact with air by smoothing the top and pouring clarified butter over it until it was completely covered. Nowadays you can cover it with plastic wrap pressed close over the top of the mixture.

Make pâté in small amounts because it doesn’t freeze successfully and needs to be eaten up within a few days to a week at most. Pâté is good with a taste of mustard or tart jelly—red currant or crab apple—or with chutney. It’s good served cold with sliced apples, crackers, toast fingers, or melba toast, or to make fancy sandwiches.

PLAIN PÂTÉ Cook ½ lb. livers slowly in 2 T. butter with 2 chopped onions until the onion is soft and the pink in the liver has disappeared. Remove the liver, mash with a fork, and force it through a sieve, or blend until smooth. To the sieved liver, add ½ c. sour cream. Salt and pepper to taste.

GOURMET SEASONED PÂTÉ Saute 1 large onion, chopped, and 2 minced cloves of garlic in ½ c. butter until vegetables are limp. Add 1 lb. chicken livers and saute until pink has thoroughly disappeared. Add tarragon (1 T. if fresh or ½ t. if dried), 1 t. salt, ½ t. freshly cracked black pepper, 1 t. dried thyme, ½ t. cayenne pepper, ½ t. cloves, and ½ t. allspice. Process mixture until smooth. Add 3 T. dry sherry, and blend again until smooth. Pour into bowl, cover, and refrigerate overnight before serving.

Unfinished Eggs. When butchering cull hens, eventually you’re going to encounter one with a cluster of eggs of all sizes—from the size of grains of sand to soybeans size to almost-regular-egg size. They look like little egg yolks. That’s what they are, for the addition of an egg white and a shell are the last 2 steps on a hen’s ovarian conveyer belt. The sight will give you awful pangs of guilt, as you will have obviously goofed in your culling and butchered a hard-working egg layer. At least you can avoid wasting the unborn eggs. Carefully remove them, rinse, and save. Use fairly soon. They are good food. You can cook them in the chicken broth for soups, scramble them together with regular eggs, or stir into any rice-vegetable mixture that you want to turn into a fried rice.

CHICKEN-FOOT SOUP Scald feet with boiling water until the skin and claw cases will peel off. Then place cleaned feet in cold salted water and cook slowly with stew-type vegetables and seasonings to taste.

BARBECUED CHICKEN WINGS You’ll need 20 chicken wings, ¼ c. soy sauce, ¼ c. honey, 1 T. vinegar, and ½ t.
**Serving the Bird Whole**

**About Trussing.** A roasting bird is “trussed” by drawing the thighs and wings close up against the body and fastening them securely with skewers or tying them with a string. Trussing keeps those appendages from drying up while the thicker parts of the bird are still baking.

**Roasting a Bird (Chicken, Duck, etc.).** Roast 2-2½-lb. chickens at 400°F for 1-1½ hours, and they will brown well. Roast 2½-4-lb. chickens at 400°F for 1½ to 2½ hours. (If cooked at a lower temperature they will require a longer time to cook and won’t be as brown.) Roast 4-8-lb. chickens at 325°F for 3-5 hours. If your bird is stuffed with a dressing, allow 15-20 minutes additional cooking time. (See “Cooking a Turkey” under “Turkeys” for instructions on larger birds.)

**About Stuffing.** The bird may be stuffed through both the opening you made to remove the crop and in the abdominal cavity. Stuff sufficiently to fill it, but loosely, since stuffing expands when cooking. When the body is full of stuffing, sew up the skin or close with a combination of skewers and thread. If the sides are very slack, skewers alone could do the job. The loose skin of the neck is drawn over the stuffing in that neck cavity and sewn or skewered. A bird for roasting may be frozen with the stuffing in it for up to 2 months. Make the stuffing ahead and prechill so it is thoroughly cold before you stuff and freeze the bird. (See Chapter 3 for stuffing recipes.)

**BARBECUED BIRD** You’ll need 1 whole (4-5 lb.) chicken or duck, salt, and pepper. Have plenty of hot coals ready. Season inside cavity. Fasten bird securely to rotisserie rod (or a pole over an open pit). Salt and pepper the outside of the bird. Position bird 6-12 inches from the coals. Enjoy the aroma as the bird sizzles for 2½-3 hours. When it’s done, serve it piping hot.

**Cutting up the Bird**

**A Halved Broiler.** Traditionally, you start with a bird in the 1 to 1½-lb. range. Split the bird into 2 halves, down one side of the backbone and along the breastbone. If you want, you can also cut it along the other side of the backbone and remove the bone completely. To freeze the broiler, place 2 pieces of freezer paper between the halves to make it easy to separate them, then wrap well in a plastic bag or freezer paper. Label with date of freezing and “broiler.”

**Quartered Bird.** You just cut each half in half again so that you end up with 2 breast-wing pieces and 2 thigh-drumstick pieces.

**Making Old-Time Frying Pieces.** Cut off both the legs and wings before opening the abdomen to remove the entrails. But a person can cut them off afterwards, too. You may leave the drumstick connected to the thigh and serve the resulting larger piece as one, or you can find the joint by wiggling it with one hand and feeling for it with the other and then cut them apart. To get the thigh off the body, place the chicken on its back. Pull the thigh away from the body. Cut through the skin that is thus exposed, between the thigh and the abdomen. Now bend the thigh sharply away from the body cavity until the ball of the thighbone pops from the hip socket. Cut between ball and socket and finish separating the thigh from the body. Do the other leg the same way.

Next comes the wing-joint cut to make a big piece. You press the top bone of one wing against the body. Feel for the shoulder ball-and-socket joint. Cut through the joint, pull wing outward from body, and cut it from body. By this technique a portion of breast meat will come away with the wing. (It makes the wing piece more significant than it is otherwise.) If you prefer just wing and no breast meat with it, pull one wing upward to expose the joint connecting the outer wing to the body and cut through that joint. Do the other wing the same way.

The last step is cutting up the body. Insert knife blade into the cavity of the bird. Cut parallel to the backbone, slicing through the ribs at approximately the halfway point. Do the same thing on the other side. Pull apart the breast and back. You’ll see the meat-covered shoulder blades that unite them. Slice down through these bones to separate the breast section completely from the back. Cut across the backbone where the chicken’s rib cage ends to divide the back into 2 pieces. To finish, place the breast skin-side up and cut down the length of the breastbone to divide it into 2 equal pieces. If this were a very large bird, like a turkey or goose, you could cut across extra times to get more breast pieces.

**Freezing, Canning, or Drying Poultry and Other Small Stock Meat**

**Freezing a Roaster.** Trim away and discard the excess fat. Cool bird in the refrigerator or soak it in ice water until it is well cooled. This may take 6-8 hours. Then drain thoroughly, for 20 minutes (the dryer it is when it goes into the freezer, the better it will keep). Wrap the giblets in freezer paper. Put the giblets into the bird’s empty cavity, then slip the bird containing giblets into a plastic bag. Lower the bird in bag into a pan of lukewarm water. Be careful not to let any water get inside the bag. The water will press the plastic against the bird and expel all air. Twist tightly the part of the bag remaining out of the water. Then loop the tag end of plastic double and fasten with a wire twist or a strong rubber band.

**Freezing Cut-Up Chicken.** Chicken in pieces is more compact than a roaster, and so takes up less freezer space. The freezer life of a chicken is about 6 or 7 months. If you freeze cooked chicken, it will stay prime only 2 or 3 months.

**Canning Poultry, Small Game, or Rabbits.** Use cut-up pieces. Remove as much bone as possible so it will pack more compactly. You can include the neck, but do something else with the gizzard, heart, and liver. You could can the gizzards and hearts separately. Or make broth with them and the wings and use it to cover your canned meaty pieces. Or, instead of canning the wings, which are bony and don’t have much meat, use them for old-hen recipes, soups, or dog biscuits. Boil chicken pieces 1 hour to precook. You can bone them and can the meat pieces for creamed chicken, sandwiches, or chicken a la king. Or can on the bone.

**HOT PACKING, ON THE BONE.** Precook until no pink color is left, even at the center of the pieces. Add 1 t. salt per quart jar. Pack clean quart jars loosely with precooked, hot pieces. Pour hot chicken broth over the meat. (You’ll need ½-¾ c. per quart.) Leave 1 inch of headspace. Put on lids and process in pressure canner at 10 lb. for 65 minutes for
CANNING GIBLETS. Precook in pan until cooked through. Add ½ t. salt per pint. Pack hot. Add broth to cover giblets, leaving 1 inch headspace. Process in a pressure canner at 10 lb. for 75 minutes (for pints).

HOT PACK, NO BONE. Precook. Remove bones. Fill jars immediately, leaving 1 inch headroom. Process in pressure canner at 10 lb. pressure for 75 minutes for pints, 90 minutes for quarts.

RAW PACKING ON THE BONE, NO LIQUID. Wash pint or quart jars in hot soapy water, then rinse. Pack raw chicken pieces into jar, drumsticks and thighs against the outer glass, breasts in the center. Add 1 t. salt per quart. Wipe jar rim dry. Put on lid. Process in pressure canner at 10 lb. pressure, 80 minutes for quarts.

Drying Chicken. Start with freshly butchered chicken. (Or turkey, but not fat poultry such as duck or goose; fat poultry meat doesn’t dry well.) First precook. Cool, remove skin, bones, and all fat. Cut all remaining meat into equal-sized cubes no more than ¼–½-inch square. Distribute these cubes across your drying surface in a very thin layer. Dry in oven or dehydrator 4 hours at 140°F, then continue at 130°F until drying is finished. It helps to stir once in a while and turn trays occasionally. If sun drying, it will take 2 or 3 days. You’re done when the meat cubes are dry all the way to the center and so hard they can’t easily be cut with a knife.

GOOD RECIPES FOR OLD HENS! You can use these recipes for other small, tough old creatures (like rabbit) simply by substituting “creature” for “chicken.”

CHICKEN AND NOODLES. This recipe is delicious and warms up well. Put your stewing hen in a deep pan. Add all giblets except liver. Cover with water and add ½ t. salt for each pound of chicken. Add 1 carrot, 1 small onion, 1 clove, and 3 peppercorns. Bring to a boil, reduce heat, and simmer until the meat will come off the bones and is very tender. That will require at least several hours or more, depending on how tough your old bird is. Cool it down enough to work with. Take the chicken off the bones and discard bones, skin, and cartilage. Return the meat to the broth. Mash the vegetables in the broth. When you’re almost ready to serve this, heat it to boiling. Pour in noodles and cook, frequently stirring to make sure nothing is sticking, until the noodles are done. Serve. I always make this with homemade egg noodles.

CHICKEN STEW. Prepare the chicken as for “Chicken and Noodles” (above), but instead of adding noodles, add potatoes, more carrots and onions, and peas (or any other vegetables you have and enjoy in stew). Cook until tender.

“CREAM” OF CHICKEN SOUP. Prepare the chicken as for “Chicken and Noodles” (above), but instead of adding noodles, puree vegetables and add them to the chicken and broth.

CHICKEN POT PIE. Make “Chicken Stew” (above) or use leftover chicken stew to make this. Brown 7 T. flour in a frying pan with 4 T. butter. Gradually add enough chicken broth to make a good gravy (about 2½ c.). Butter a baking dish. Put the vegetables and meat from your chicken stew into the dish. (Hold back any excess broth to use in another recipe.) Pour the gravy over it. Make a dumpling dough by your favorite recipe (see recipes in Chapter 3). Drop the dumpling dough by marbles or teaspoonfuls (depending on how you like to make it) on top of the meat and gravy. Bake at 350°F until the dumplings are done.

CHICKEN AND DRESSING. Cook the chicken and giblets (except liver) until you can easily separate the meat from the bones. Let cool and remove bones and cartilage. Then grind the chicken skin and giblets and add to the meat. The chicken meat is nicest sliced thin. Make a bread dressing base from (preferably homemade) bread plus egg, seasonings, and chicken broth and milk (see recipes in Chapter 3). In an oven pan put a layer of dressing, then a layer of chicken, a layer of dressing again, and so on. Bake, covered, for 40 minutes at 350°F.

IVY’S CHICKEN LOAF. Ivy Issacson is a beautiful person, a real old-timer. Her husband, Dick, has experience driving oxen and knows how to make an ox yoke, starting with the right sized tree. Here’s her recipe: First, boil your old hen by the “Chicken Noodle” recipe (minus the salt), until it is so tender you can pick out the bones and discard them. Keep the chicken meat and broth. Mix 1 small loaf bread torn in pieces with 4 c. corn bread and add enough of the chicken broth to moisten the breads thoroughly. Now add ½–1 c. chopped celery, ½–1 c. chopped onion, salt, pepper, and sage to taste. Place mixture in a buttered 12 x 15-inch pan. Cover with the chicken meat. Mix ½ c. melted butter with ¼ c. flour. Add 2 c. milk. Cook same as any white sauce until thickened. Cool. Add 6 eggs, beaten. Pour over chicken. Sprinkle with buttered bread crumbs. Bake at 350°F for 1 hour. This will give you 15 to 20 servings. Good to take to a potluck!
GERTRUDE JOHNSON'S CHICKEN SPREAD
Cut a stewing chicken of at least 2 lb. into pieces, and place it in a casserole that has a tight-fitting lid. Dot with 4 T. butter. Add 1 onion, peeled and quartered; 2 carrots, halved; 2 ribs celery, halved; and 4 peppercorns. Lay 3 lemon slices on top. Cover casserole tightly and bake for 3 hours at 325°F or until chicken is very tender. You might want to just serve the chicken for supper right at this point in the recipe! Otherwise, remove chicken and cool. Discard the vegetables, spices, bones, and skin. Run meat through a meat grinder 2 or 3 times, or whirl it in a food processor until smooth. Put chicken in a mixing bowl and blend in 4-8 T. of softened butter. Stir in ½ t. Worcestershire sauce, salt, and pepper to taste. Press your chicken spread into small jars. Pour a ½-inch layer of clarified butter over the spread in each jar. Cover tightly and refrigerate until wanted to make sandwiches.

DOG BISCUITS
You can use the excess broth from any old hen recipe to make this, or you could cook the chicken specially to get broth, use the meat in another recipe, and use the broth for dog biscuits. (Actually you can make this recipe with other types of meat broth, too.) This recipe will yield 60 medium-sized dog biscuits which your pet will consider a great treat. Mix together 3½ c. unbleached flour, 2 c. whole wheat flour, 1 c. rye flour, 2 c. cracked wheat, 1 c. commer, and ½ c. skim milk powder. On the side, dissolve 1 T. (or 1 pkg.) yeast in 3½ c. lukewarm chicken broth. The richer this broth is, the more your dog will like the biscuits. Let yeast-broth mixture sit 10 minutes, then stir in the flour mixture. Roll resulting dough out ½ inch thick. Cut dog biscuit shapes from dough. Brush biscuits with egg wash. Bake on greased cookie sheets at 300°F for 45 minutes. Then turn oven off and leave biscuits in there overnight to finish hardening.

Cleaning and Using Feathers
Now that you've taken care of the meat, you can get back to the feathers. You can make and sell jewelry, art objects, and trout lures from feathers. Or clothing. Or a quilt. But first you have to clean them.

CLEANING FEATHERS
Cleaning Nice Feathers. Wash them in warm water with a little detergent in it, then wash them again in a fresh tub of water with detergent (or washing soda or borax). Then rinse them, and place them into a clean cheesecloth bag or gunny sack and slowly dry. Fluff the feathers several times a day. If you hang them out on the line, dry them in the shade because the sun will bake the life out of them. Or you can dry the feathers by putting them into a slow oven for about half an hour, then removing them, then putting them back into the oven 2 or 3 times. The oven must not be too hot. Or you can suspend the bags from the ceiling of a warm kitchen, or some similarly very warm place.

Cleaning Not-So-Nice Feathers. Ducks and geese are not generally subject to the kind of feather parasites that afflict chickens. You could just throw away the feathers and resolve to trade in your dirty-feathered poultry variety for waterfowl. Or you can struggle on. You won't get good results from what are called "dead" feathers. Those are the ones that the chickens lose in their regular molting process and your children find in the yard or on the chicken-house floor. They will be hard to clean and not as lively and nice as freshly plucked ones.

Pat Woods, Sedro-Woolley, WA, wrote me that a neighboring chicken farmer just presented her with 6 great big sacks of feathers in this condition, and what should she do? Personally, I wouldn't bring home a batch of feathers that had critters, because next thing you'll know they'll be all over your own farm. Just tell your well-intentioned neighbors to keep their feathers. So I'm writing to her and writing up her situation for the book at the same time. (I'm always glad to get questions from people. It tells me what people are needing to know and helps me make this book a more useful one for its readers.)

If somebody gives you a mess of feathers that are not in good shape (and that's the way you'll usually get them)—I mean, containing lice and other creepy-crawlers along with the dirt, droppings, and so on—and you want to keep them, here is what you do.

You'll have to pick out rocks, straw, sticks, and major globs of flop by hand. If there are no bugs, go ahead and strip the wing and other large feathers to get those big quills out of the way. It takes a long time to strip feathers. And cut off the sharp tips on the shorter feathers. If there are bugs, you'll want to give it all a very antiseptic laundering first. Sew or tie the feathers into a bag. If you've got something like old scrim curtains, the kind you can look through, that's perfect, because they let the dirt out. But any loosely woven cloth will do. Then you put the whole thing in the washing machine, and wash it repeatedly until you're satisfied. Or wash the bag by hand, squeezing it and letting it fill, again and again. You can use a soap suitable for wool, even some bleach, and warm, but not boiling hot, water unless the bug problem is bad. In that case, a dose of boiling water in a pan on the stove may be the only answer for your "presoak" cycle.

So if you've got questions too, do write me—don't feel embarrassed about it. If I don't know, I'll just tell you so, or maybe I can find out, and then we'll both learn something. If you have a question, suggestion, or need another copy of this book, or want to know about other books I've written, or the latest edition, find me at www.carlaemery.com.

Drying Feathers. If you have a dryer, put your washed sack of feathers inside a pillowcase for extra coverage, then just go ahead and dry them on a very low heat setting. If not, hang the feathers inside a very loosely woven bag in the shade on your clothesline or some place where it can get lots of air. Give the bag an occasional shake. Or you can spread them on screens placed above the floor, or even on the floor itself, if you make sure to turn them over often enough for thorough drying. The main thing is to get them dry as quickly as possible without exposing them to direct sunshine. If the feathers don't dry quickly enough, they will start to deteriorate in quality, becoming fibrous and, ultimately, decomposing.

Using Feathers: Whatever feathers you use to stuff, they must be absolutely dry. The higher your percentage of the more down-type feathers, the better. Don't use the quills (wing and tail feathers) at all, unless you strip the fluffy part off the quill base and use it without the quill. You can sell well-washed waterfowl down. It takes about 5 ducks to make a pound of down. Or you can make something of your own with it. Make pillows. Or a quilt.

Making a Feather Quilt. Lay the feathers, still in their cheesecloth bags, upon the bottom layer of the quilt as it is stretched out on your quilting frame. Then put your quilt...
cover on, tack it down, and sew or tie it. Or the feathers could be placed directly between layers of cheesecloth, and then the quilt made over that. If this method is to be used, stitch over the entire cheesecloth and feather layer (and quilt, too, if you wish) to create an effect of "diamonds" or "squares." This will keep the feathers from shifting out of place and bunching. Another technique is to sew 2 layers of cloth together around 3 edges leaving the top open, and then sewing from the head to the toe of the quilt, creating long pockets into which you stuff the feathers and down, then sewing the top edge closed. Such quilts can be washed very occasionally if care is used, but it is preferable to have removable covers, and thus protect the feathers from washing as much as possible. To make pillows and ticks, use commercial ticking and fill them as slack or full as you like. But the first time, make them fuller than you think you want, because they will gradually pack. Use a ratio of about ¼ small body feathers to ¾ down to get a resilient pillow. Sew double-stitched seams to keep the feathers in. Make sure you have the feathers in a special inside layer, because you don't want to have to pull a needle through the feather section as you quilt the top. It will pull feathers out with it every time.

**Making a Feather Bed.** Use regular twill ticking to contain the feathers. Sew double seams so you won't have feathers creeping out. Leave one end open. Pour in 10 to 20 lb. of dry, clean feathers and sew it up. Feather quilts go on top of you; feather mattresses beneath you. With feathers above and below in that manner, you can sleep warm, even in temperatures 50°F below zero, and I kid you not. That's what the settlers in places like Vermont—where they had no heat in their homes at night—used for bedding.

**Feather-Stuffed Clothing.** Items such as down jackets can be made by creating 2–3-inch channels in the garment to keep the feathers evenly distributed. For clothing use a higher percentage of down, up to 90 percent. Use a down-proof lining, and sew double seams everywhere.

**Making Old-Time Quill Pens.** The second, third, and fourth quills of the wing are the best for this. If you want them to be clear, put the feather into boiling alum water for 5–10 minutes, then scrape its outer "skin" off. After this, dry the quills in hot sand on a stove, or before the fire.

There exist strange, believe-it-or-not life paradoxes: you get by giving; risk can provide safety; and great, breakthrough understandings that change a person's life and set them back on the right road can come in lulls between episodes of fierce struggle, born of action. I have a theory...
that you can't go and contemplate dandelions and have anything important happen in your head—unless you are first bone tired from doing something you think is important. But, on the other hand, I don't think you can get along on pure action either. So spend some time with the dandelions. Or in the garden. Or with the milk cow. Or watching your chickens. In those lovely, quiet times your head gets a chance to tell you a few things you were needing to be told. Your own head can be your best friend, if you listen.

**Turkey Breeds**

Don't buy just 1 turkey. Turkeys don't like being alone, and a solitary one may refuse to eat and, consequently, die of starvation. Or the lonely bird may adopt a human. Margie Minard of Mt. Vernon, OH, wrote me: "We have a pair of bronze turkeys. I love them! Their names are Ben Franklin and Betsy Ross. Betsy has been sitting a nest for nearly 3 weeks. Ben has been lonesome since Betsy has been so busy and has become my buddy. He goes to sleep every night on his perch in the barnyard, but every morning he's waiting for me to get up and go out on the porch and have my coffee with him. I talk to him, he peeps back, and we share an apple. Our pair of turkeys seems to be very sweet and very gentle creatures." (A word of caution, here: I wouldn't recommend getting to be that good friends with any farm animals unless you're planning to keep them for breeding.)

Dynah Geisel of Missoula, MT, reported: "I used to keep adult turkeys in the hope of raising my own babies. However, the females wanted to be pets, following me everywhere, trying to come into the house, wanting to sit in my lap outside, etc. The males at around 1 year of age became so mean that they terrified grown men and were a real danger to little children." Indeed, these big turkey toms (a tom is a male) can be very aggressive and dangerous. Once I had a band of gobblers that sneaked up and attacked my husband, Mike, when they were free-ranging. (They didn't stay free-ranging!) Yet I've also had free-ranging turkeys that got along fine with everybody.

Turkeys, like the other poultry, come in different kinds and sizes, but even the small ones are sizable birds. If you're going to raise turkeys, you'll need to invest in a large deep freeze and, even so, be cautious that you don't raise more than you can use. Turkeys have received a lot of bad press about being hard to raise. They are a little slow to learn how to drink and eat, and a little more vulnerable to disease than other poultry, if kept in large numbers. (Crowded birds in general are more vulnerable to disease and parasites.) Other important issues are the initial high-cost of pouls, the large amounts they will need to eat (expensive if they are on all-commercial diet), and the large amount of turkey meat you will end up with. Most families would want to raise 6–12 turkeys per year for family use. For commercial growing, 1 acre of land supports between 100 and 150 turkeys.

All turkeys have brightly colored, bizarre-looking folds of skin hanging down from their heads called "wattles." Somebody asked me what wattles are for. I don't know. A full-grown gobbler is an amazingly ugly creature, or handsome, depending on your point of view. Mature toms gobble noisily when strangers approach.

For my summary of the most important things about growing turkeys (that aren't already covered under "Chickens"), here goes.

**Turkey Breeds**

**THE BROAD-BREASTEDS:** The biggest of the turkey breeds (also known as the "heavies") are the broad-breasted, either the traditional Broad-Breasted Bronze or the newer Broad-Breasted White. The Broad-Breasted Bronze is the brown- or black-feathered turkey, but since dark-feathered birds end up looking "dirty" when plucked, the white varieties are becoming the commercial choice.

Broad-Breasted Whites grow large, even larger than Bronzes. These birds grow very fast, have exceptionally large, meaty breasts and may ultimately dress out to 25 lb. (hens) or even 45 lb. (toms). (Other poultry breeds don't have such a striking difference in ultimate weights between the sexes.) You can reasonably send one of these to roast any time from 12 lb. on up. Both Bronzes and Whites make good large roasters at 24–28 weeks. As turkeys (and other poultry) get larger, their feed conversion efficiency and rate of gain decreases. The usual goal is to grow an 18-lb. tom (12-lb. hen), in about 5 months, or a 25-lb. tom in 6 months. Hens can be butchered at only 13 weeks as fryer-roasters or at 20 weeks to make medium roasters (about 14 lb.). If left to full maturity, they get heavier yet. Toms can weigh 50 to 60 lb. at maturity, but by then the meat is toughening. Because the Broad-Breasteds can put on more flesh weight than the others they should be started a month earlier than a medium or light breed.

Many formerly abundant turkeys breeds are now extinct or very near extinct due to the extent to which the market has become dominated by the 2 broad-breasted breeds. But some still exist.

Many formerly abundant turkeys breeds are now extinct or very near extinct due to the extent to which the market has become dominated by the 2 broad-breasted breeds. But some still exist.
Artificial Insemination, or AI.

Somewhere between a few days and a few weeks. Sperm then stored inside her will fertilize her eggs for several days. And you can get naturally mating Bronze turkeys from Wish Poultry, Box 862, Prairie City, OR 97869, spring hatch only. The Bronze is a large bird that does relatively well either in confinement or on range.

Beltsville Whites. These are smaller turkeys; they make good broilers at 15–16 weeks and good medium-size roasters at 24 weeks. Beltsvilles do not convert feed as efficiently as the Broad-Breasted varieties, but they are usually cheaper to buy as pouls.

Bourbon Reds, Royal Palms. The reds and palms are both medium-sized turkeys. The Royal Palm is the only major turkey breed whose hens are dependable brooders.

Others. Some sources sell Wild Turkeys. These are hardy, good flyers, and smaller than the commercial breeds—a “light” variety. Because they are being raised in order for the bird to make a comeback in the wild, check with your state game regulatory agency before ordering any. You may need a permit. The Wild Turkey breed needs a high-protein feed, like game-bird starter. Other turkey breeds are Black Spanish, Narragansetts, Blue Slates, and a rare Guatemalan turkey, also called the “ocellated turkey.”

Turkey Reproduction

Most people start by mail-ordering turkey pouls just as is done with chickens, but you can breed your own. Keeping turkey breeders over winter is expensive because of their sizable food consumption. A broad-breasted tom can eat as much as 250 lb. of feed per year. Letting a bird hatch its own eggs is an iffy method of building a flock because sometimes hatchability is not good. On the other hand, it’s nice to know that at least some of the domestic turkey species could survive without artificial insemination and electricity. Growing the better part of your turkey food keeps the expense down. And if you are well-informed about what you’re doing, you can avoid the pitfalls.

A good time to buy pouls being reared to be breeders is 8 months before you’ll want the eggs. Use only the birds that best represent the characteristics you want to breed for. For light-breed turkeys, 1 tom per 20 hens can do the job. Medium-heavy breed turkeys need 1 tom per 18 hens. Heavy-breed turkeys need 1 tom per 16 hens. But you should have at least 2 toms to ensure fertility and performance since one may die or just not have the right stuff.

Commercial breeders get the birds started early by stimulating the toms with extended light hours 4 weeks before mating, and hens 3 weeks before egg production with 13–14 hours of at least 50–watt lighting or sunlight.

Turkey Sex:

When hens begin to lay, they begin to mate. The toms strut and court them. The hen chooses the tom she prefers, squats near him, and with luck, he responds and mounts her. If he doesn’t respond she loses interest in males for a while. (I can relate to that.) Males that have been “pre-lighted” tend to respond more effectively. Sperm then stored inside her will fertilize her eggs for somewhere between a few days and a few weeks.

Artificial Insemination, or AI. The breeds that are not heavy-breasted and are old genetic lines can usually reproduce naturally. The commercial, heavy-breasted breeds of turkey are not as fertile because that body type selected for by growers, with its very large breast, has some technical difficulties in achieving fertilization naturally because that big meaty breast is too much in the way. So heavy-turkey growers either inseminate artificially completely or attempt to raise the fertility rate by supplementing nature with AI. Insanminating turkeys is not as hard as it sounds.

Milk the Tom.

First you capture the tom and the lady and have them close by because turkey semen must be used within 30 minutes of collection. The ideal AI schedule is to inseminate once, wait 4 days, and inseminate once more; after that, do it once every 2–3 weeks while the egg-laying season is on. Toms can donate 2–3 times/week. You need at least 2 people to do the job. You “milk” the tom by flipping him on his back (or you can have him upright and work on him with his legs spread a little from his backside) and stroking his abdomen and pushing his tail up and toward his head. His organ enlarges, protrudes a little bit and then someone must grab it high up and stroke downward just like you’re milking a cow. That’s it. Have something ready in which to collect the semen. You’ll get only a half cubic centimeter or less of it—less than ½ teaspoon.

How to AI the Hen.

Get her into position by flipping the hen on her back, flipping up her tail, and everting the cloaca. Now pour the tom’s semen into it. But for best results, it’s not that simple. Ideally, you will expose the opening of the oviduct and use a glass or plastic straw or a small needle-less syringe to place the semen about 1½ inches into that oviduct. If you can’t find the oviduct you may have a hen that’s not in lay, in which case it’s all a waste of time anyway.

Egg Production:

Have available nests that are 24 inches high by 18 inches wide by 24 inches deep with comfy litter in them in a dimly lit area before laying will start—1 nest for every 4 or 5 hens. For a lot of hens you could supply a 3 x 6-foot community nest. One of those can accommodate about 20 hens. Supply litter generously and gather eggs frequently during the laying season because turkeys like to lay together and tend to step on and break each other’s eggs. Heavy hens may lay 50 eggs, medium hens 50–70 eggs, light turkey varieties 85–100 per bird. Turkey eggs are good to eat, but are generally too valuable as the progenitor of another turkey to waste in an omelet. As with chickens, turkey egg production is best the first year and then each succeeding year decreases about 20 percent. Like chickens, egg size increases the second year.

Natural Brooding:

Broodiness is common among turkeys, but full-fledged mothering ability is not. At least, among the most modern breeds, the turkey hens simply don’t have the right sense about the care of poult’s. Ideally, your turkey would lay 15–20 eggs, then stop and brood them. At least take the eggs until you have a reasonably sized clutch for the hen to sit on. Or let chickens, ducks, or geese brood the eggs. A medium-size chicken can cover 6–7 turkey eggs. The incubation period will be 28 days.

I think the retention of breeds that have the requisite instincts and experience to reproduce on their own is important, and the people who raise these are doing the homestead market a valuable service. If you have a mothering turkey, provide a turkey-sized A-frame inside the pen, 1 for each hen, with straw inside to make into a nest. The
nests can be about 14 by 24 inches, on the ground. She'll lay eggs in there and brood them. Some growers slaughter the breeders as soon as the poults are independent of them so as not to have to feed them over winter. Old breeders can be cooked like any other turkey—only longer.

**Incubating Turkey Eggs:** If you're planning to incubate, broodiness is a problem and you'll want to chase broodys off the nest and treat them like you do a chicken with unwanted broodiness (see "Discouraging a Broody Bird" under "Chickens"). The growers who incubate eggs feel that it makes more economic sense to keep those hens turkeys laying and they will, of course, stop immediately if allowed to stay broody. Incubate turkey eggs for 28 days at 102°F in a still-air incubator or 99.5°F in a circulated-air incubator. Relative humidity during the first 25 days should be about 62 percent (dry bulb reading 99.5°F; wet bulb reading 87.5°F). During the last 3 days it should be about 70 percent (dry bulb 99.5°F; wet bulb 90°F). Which brings you to the directions for raising poults.

**Brooding Poults**

A "poult" is a just-hatched turkey.

**Mail-Order Poults:** Order your poults to arrive after the weather has turned warm. Or you may be able to buy them at your local feed store. They cost $3 to $5 each, depending on the breed. To mail-order turkey poults you need to get your order in early, by midwinter. Check on delivery schedules since they are hatched during only a few months of the year—about March to July. Poults delivered to you in late May or early June will have just the right amount of time to reach finished weights before Thanksgiving. If you begin your brooding after warm weather has arrived it will be easier and cheaper.

**Sanitation:** Do make sure you clean the brooding area, disinfect it, then let it stand empty for a month before the turkey poults move in—if it has previously held chickens. This precaution is because turkeys are susceptible to coccidiosis and blackhead disease, both of which are carried in chicken droppings. Still, the most severe turkey disease problems occur in large commercial flocks. Small numbers of turkeys raised and then put into the deep freeze seldom have communicable disease problems.

**Brooding:** See "Brooding Chicks" under "Chickens" for further information, because the basics are the same. You can brood in a cardboard box with an electric light or a shed-room or in a penned-off space in a barn. If you are using a thermostat-controlled brooder, brood Broad-Breasted Whites at 100°F the first week and Broad-Breasted Bronze at 95°F the first week, and then reduce 5 degrees a week just as with other young poultry. Depending on your climate and the time of year you start them, they may need supplementary heat as little as a few days or as much as the full 8 weeks. If poults get wet and chilled, they must have heat to recover. As with other poultry, most of the work and worry with turkeys comes in the first 8 weeks. It's important to check on poults frequently and observe them closely, even after the first few days, to see if there is some problem.

**Teaching Poults to Drink and Eat.** You can use chicken feeding and watering equipment for turkeys. As soon as your mail-order poults arrive, take them one by one out of the shipping container, dip their beaks into their proper drinking container (which should be filled with lukewarm water). Then dip their beaks into their proper feed trough (which should be filled to the brim). Do this same thing morning, noon, and night for each poult for the first few days, or until they learn how to eat and drink and can do it on their own. Some people put a few chicks in with the poults to show them how; chicks are quicker learners than poults.

But don't count on that technique working. There are reports of poults having died of starvation while standing on their food. (Anyway, it's unhealthy for them to eat food that has been spread on the floor or ground and gets mixed with feces.) Unlike chickens, turkeys seldom scratch to find food. Instead they peck at something that catches their attention. So an additional good teaching technique is to put strips of aluminum foil or some brightly colored marbles both in their feeders and waterers to catch their attention and encourage them to start picking at it. Or you can lay their food out on clean sheets of white paper towel. Or put it in low-sided box tops like oatmeal carton lids. Another technique to help them find that feed and water is to supply intense light, such as 150 watts, 24 hours a day for the first 3 days.

After those first 3 days or so, you can take away the chicks so they won't get trampled. Move the feed from paper towels or box tops into the regular metal feeder, and fill the trough only ¾ full.

**Commercial Turkey Food.** Most local feed stores don't carry turkey starter mash, although that is a very suitable food for the poults. So, the poults can be fed chick-starter rations with plenty of water. In either case the feed will contain a coccidiostat (antibiotic to prevent coccidiosis). They'll eat the starter ration for their first 8 weeks. Then gradually shift them to a grower's ration. At about 16 weeks of age they are gradually shifted to a finishing ration. Growing and finishing rations are not usually medicated. Supply grit. If you are using any medicated feeds for older birds, be sure and stop offering them at least a week before slaughter and preferably longer.

**About Antibiotic Withdrawal.** Food writer Lane Morgan, who reviewed this book, complained that in the chicken section it says to withhold medication for 5 days, and here it says a week. Actually, never medicating them is best. Or, lacking that, stopping as long before slaughter as possible. Or 7 days. Or 5. How desperately hungry are you? Starvation is worse than a little antibiotic in your protein. These things are judgment calls, not absolutes. The basic principle here is that the less antibiotic you feed your animals, the better—for them and for you. Routine antibiotic-feeding results in an animal whose own immune system is underdeveloped and under-functional. That's true whether it's livestock or your children. Antibiotics are a quick fix for which we pay a long-term price in the development of antibiotic-resistant varieties of whatever we were fighting in the first place. Livestock diseases often transfer over and become human illnesses too, and this can also happen with antibiotic-resistant varieties of livestock illness. Simply speaking, the more you use antibiotics (or pesticide, herbicide, fungicide, etc.), the sooner they won't work any more. Basically, if you have fed your animals antibiotics, the longer between that feeding and your consumption of the meat, the better.

**Home-Devised Poult Diet (or Diet Supplement).** It helps to supplement the chick starter at first with scrambled...
eggs or chopped hard-boiled eggs because the fast-growing pouls need a lot of protein at first and, like broiler chicks, can develop leg problems without it. Or you can start them on home-grown food using the same rations as for geese (see “Feeding Goslings” under “The Waterfowl”), only leaving out the water poured over the food. They like crumbled cornbread, too, and can make good use of fresh whole or skim milk served from their first week on. Other good foods for them are eggs scrambled with milk and mixed with any kind of flour or fine grain—ground or rolled oats, barley, or corn, etc. They love bugs, especially maggots. They’ll eat boiled meats, including butchering leftovers. A liquid mixed with any fine grain makes a home-grown mash for them.

Birds on a home-devised diet need to be able to get out and forage when weather permits. Later they can handle more coarsely cracked corn and wheat if they have grit. Large-scale growers may plant special crops of soybeans, alfalfa, rape, or kale for them. For just a few birds you can let them find their own food so long as it’s not something forbidden. They can benefit from greens like Swiss chard, rape, alfalfa, cabbage, lettuce, and so on for about a quarter of their diet. Gradually add a combination of cracked corn, wheat, oats and greens. (See the chicken section for more on useful home-devised diet options.) Or you can supplement commercial rations with such combinations. The birds must have insoluble grit to be able to make use of whole grains and other fibrous foods.

Of Turkey Housing and Yards

**Turkey Space:** Until they’re 8 weeks old, the pouls can get along on a square foot of space per bird. But they’ll grow fast and need more square footage per bird before butchering time. A peculiarity of turkeys is the great difference in size between toms and hens. In an all-tom flock, you’d eventually need 5 square feet of floor space per bird. An all-hen flock could manage with 3 square feet per bird. Another consideration is that some turkey breeds are considerably smaller than others. Those smaller breeds could grow in even less space. Breeders require more space than birds simply being grown for slaughter: 6–8 square feet per bird. In general, the more space you can provide, the better your poultry will do.

**Turkey Yards:** You can raise turkeys in complete confinement, but providing their house with an attached fenced yard would be nicer. The yard should be well-drained ground with no puddles, or pavement, or gravel, or fenced pasture, or rotted pastures. Their shelter house has its uses, too. Confining young turkeys during rainy weather will keep them out of wet grass. Wet pouls can easily get chilled, weaken, and die. Or they can be raised in an off-the-ground sunporch for exercise and sunshine. You don’t walk into a sunporch pen. You build it so that you can feed and water from outside the cage. That way you don’t carry in any blackhead disease on your shoe soles. The sunporch is the ideal way to raise turkeys in areas where they are very likely to catch diseases.

**Blackhead Disease.** This is very serious for turkeys. Chickens very seldom get blackhead though they may act as a carrier for the cecal worm that hosts the blackhead protozoan. Blackhead is the most common and destructive disease afflicting turkeys, and it can strike them at any age if they happen to pick up cecal worm eggs that contain the organism. Blackhead-affected turkeys are droopy and their droppings are brownish-colored and foamy. Their heads may look dark. The liver of a blackhead-affected turkey may have ulcers, and inflammation of the intestine may be present. If you live in a blackhead-affected area you’ll want to be careful to keep your turkeys completely away from places where chickens go. If your birds have the disease, they can be treated with drugs. It also helps to keep them on a sunporch.

**Sunporch.** A typical turkey sunporch arrangement is a pen 5 x 12 x 2 feet high, entirely supported 2–3 feet above the ground on legs, with half of it roofed over and 2 sides covered or next to another building. You can keep 1 turkey for every 5 square feet in such a sunporch. The floor can be a problem. The smaller varieties and those that will be butchered by 12–16 weeks can manage the wire floors. Large turkey varieties that are destined to be heavy roasters need a wood slat floor, or some other firm arrangement to avoid developing leg problems. Wire or slat floors do solve the sanitation problem nicely. The droppings fall through, and the birds don’t pick up any parasites and are safe from predators. However, turkeys in a sunporch do suffer the usual confinement-associated problems of feather-pulling and cannibalism. To prevent this behavior avoid overcrowding the birds, and keep them busy with food and water, roosts, fibrous foods like oats, and greens or a cabbage hung by a string for them to peck at.

**Range Arrangements.** Or you can let older birds out completely in the daytime and pen them in only at night. If shade is provided for the yard—even a row of sunflowers or corn—the birds grow faster and feather better. It will help prevent parasitic infections if this ground has not had poultry running on it for a year—or more. Like geese, turkeys can be very hard on your garden if they are not confined. Turkeys are good foragers and can find a good part of their diet if they are allowed to hunt for greens. In reasonable weather turkeys that are well feathered-out over the hips and back (about 8 weeks old) can sleep out in the open on the ground, and you can plan to have them in the deep freeze before the cold weather sets in. Adult turkeys being kept for breeders don’t need as much warmth as chickens and are quite hardy against cold weather. I once had a tom whose nose decoration froze off, but the rest of him survived a bitter winter fine.

A good design for a turkey pen is a long run with posts set into the corners to hold up high wire sides. Ground-running turkeys can be fenced in with 4–6-foot hog wire or heavy-gauge poultry wire with reinforcing barbed wire at the bottom outside of the fence. Or you can use temporary fencing moved once a week or so to keep them on clean, dry ground.
**Moving Turkeys to Yard or Range.** If you are planning to range your turkeys, be careful with the transition. Turkeys are slow learners, and if they have been previously kept in complete confinement and are suddenly set loose in the open, they will not know the use of shade to protect them from sunlight or of shelter to protect them from rain and storms. They are likely to pile in a corner and smother or not know to eat out of their new feeding arrangement. Poults in a new environment are as vulnerable as when they are a day old and must be watched as carefully and helped as carefully to learn the necessities in their new environment. Make sure they do have shade available. Make the move on the morning of a good day. Move their feeder and waterer as needed to avoid the creation of a muddy spot that could harbor disease and organisms.

**Gapeworm.** This parasite can dwell in turkeys’ bronchi and trachea. An infestation can result in a sort of pneumonia, shortage of breath, or suffocation. Birds acquire gapeworm by eating infected earthworms. The gapeworm is “6”-shaped, red-colored, and you can sometimes see them simply by opening an afflicted turkey’s mouth and looking down its windpipe. If your turkeys have ‘em, check with your vet. There is a treatment.

**Poults and Turkey Flooring:** Poults don’t do well on a dirt floor. Cover litter the first week to keep them from eating it. And don’t put them on newspapers because they’ll slip and develop bad legs. Distribute the litter very evenly and then put some sort of rough paper on top of it. Turkeys produce an exceptionally wet, copious manure. Remove wet or dirty litter daily, and add dry, clean litter. You can expect to gain about 100 lb. compost from them before the season is over.

**Turkeys That Sleep on the Floor: Piling.** Turkeys have a problem with “piling.” That happens when something frightens them, like sudden light, unexpected noise, or strange animals. Fireworks and sonic booms can cause piling. They are most likely to pile when frightened at night. Then they tend to all run and pile up in the nearest corner of their building or fence. If you see them piling you need to unpile them as soon as possible to prevent injuries and smothering of the innermost ones. A low-wattage night-light is said to help prevent piling.

Turkeys can get along permanently without roosts. If they don’t have them, like broilers, they will just sleep in the floor litter. In that case, keep the litter relatively clean and dry to prevent breast blisters and dirty feathers.

**Turkey Roosts.** Supplying roosts of either the step-ladder sort or just flat frames with perches helps avoid night piling. Flat roosts can be 1½ feet off the floor with 9–12 linear inches of roost space for each bird. Turkeys will begin to use roosts when they are about 4–5 weeks old. Older turkeys that are being raised out of confinement, with a pasture to roam in and a minimal shelter to sleep in, can benefit from roosts made of 2-inch poles or 2 × 4s laid flat. These are good when spaced about 2 feet apart and built 1½–2½ feet up off the ground, allowing at least a foot of perch space per bird.

**Butchering**

By 12–16 weeks of age turkeys can become “broilers” or “fryer roasters”; by 22–26 weeks of age they should weigh enough to be heavy roasters. If you’re not sure if the turkey is heavy enough for butchering, weigh it. Broiler–fryers are considered ready at around 4 lb. If it’s a tom and weighs 18 lb. or more, that’s good enough. (Those numbers are for Broad-Breasted Whites—lighter breeds could be considered ready to roast at lighter weights.) If your turkey is not yet up to the weight you desire, turn it loose and continue feeding it another couple of weeks, then weigh it again. If you keep turkeys longer than 6½ months, the hens may start to lay. Both toms and hens tend just to acquire fat after that age rather than to grow. And soon they’ll go into their first molt, which means many more pinfeathers to fight with. Turkeys are quieter than chickens to have around while they are young, but once the toms reach maturity (at 5 or 6 months) they will start to gobble noticeably. If you send your turkeys out to be butchered, Lane Morgan suggests scheduling will be easier if you don’t do it around Thanksgiving. Beat the rush.

**Killing a Turkey:** First, catch the bird and tie its legs. (If you can first herd the turkey into a confined area, especially a small, dark room, it helps.) Then grab its legs and tie them together. The butchering process with a turkey is basically the same as that with a chicken except that your bird is approximately 5 times bigger. It will take you about half an hour to kill and pick 1 bird, and another half hour to finish it up freezer-ready. The turkey may then be beheaded with an ax (a 2-person job, one to hold the turkey and one to chop). Another method is to suspend a cord or wire from a beam, so that the lower end comes even to about your shoulder. Hang the bird from this by its legs—head downward. Give it a sharp blow on the back of its head to stun it, then reach a sharp knife through its mouth and cut crosswise to sever the arteries in the throat. Or use a turkey-sized killing cone. And/or cut the throat just back of the jaws. Allow the bird to bleed out thoroughly.

**Picking:** To dry-pick, begin doing it immediately, while the bird’s still warm. Be careful not to tear the flesh. Pull the wing feathers and the main tail feathers by yanking them straight out. Remove the breast feathers next because the skin of the breast is tender and likely to tear if it’s cold. Jerk them straight outward from the bird as it hangs, a few at a time. After plucking the breast, move up over the body and then to the back. Finish on the neck.

Scalding is easier than dry-picking, once you’ve figured out how to manage the logistics. A metal garbage can is an easy answer. Scald the bird at 140–180°F for 30–60 seconds. (See “Scalding” under “Chickens.”) Turkey pinfeathers are probably easiest to remove under running water with pressure and a rubbing motion, or with a dull knife by applying pressure between knife and thumb, the way teenagers squeeze pimples. Then singe and eviscerate, same as chicken. Remove the oil sac on the tail as for waterfowl.

**Cooking a Turkey**

- **Turkey Broiler** Prepare, quarter, and barbecue the same as a chicken broiler. Turn frequently and baste with a good sauce each time you turn a piece.

- **PAN-FRIED TURKEY** Start with a 4–9-lb. turkey that has been cut up according to the directions for chicken frying pieces (see “Cutting Up the Bird” under “Chickens”) or as you prefer. In a bowl toss together ¼ c. flour, 1 t. paprika, ½ t. oregano, and 1 t. salt. When the flour and spices are
well mixed, pour them into a bag and shake the turkey pieces in there, 2 or 3 at a time, until each is well-coated. Fry the turkey pieces just like you would chicken, first browning them well, then cooking them covered on top of the stove or in the oven until all meat is tender and cooked through (about 1–1 ½ hours). Remove lid and continue cooking until pieces are crispy again. Remove them. Make gravy in the drippings with the leftover flour/spices mixture, and serve.

**TURKEY BURGER** If you have a lot of turkey meat, you can vary the menu by making burger out of some of it. Grind it and add flavoring ingredients such as ketchup, onion flakes, lemon juice, Worcestershire sauce, paprika, salt, pepper, etc. Shape patties and cook in your preferred manner until the meat is completely done.

**TURKEY SAUSAGE** 1 lb. ground turkey, ¼ c. seasoned bread crumbs, 2 T. chicken broth, 2 T. minced onion, 1 T. minced fresh parsley, 1 t. vegetable oil, ¼ t. ground sage, ¼ t. ground thyme, ¼ t. ground black pepper, 1 egg white. Combine and blend well all ingredients, except egg white. Beat egg with a fork and add. Shape patties and place on nonstick or oiled cookie sheet. Broil 3–4 inches from heat 4–5 minutes (until light brown). Turn and broil other side 2–3 minutes (or until cooked through).

**BOILED TURKEY** You'll need 12 c. water, 2 large carrots, 3 stalks celery, 1 quartered onion, ½ c. coarsely chopped parsley, 4 t. salt, 1 t. dried thyme (½ t. if you use powdered), ½ t. pepper, ½ t. celery seed, and ½ t. white whole for this recipe. You also need a very large kettle with a rack in the bottom, so the turkey won't stick. For a 12–14-lb. turkey use a kettle that will hold at least 12 qt. water. A canning kettle will work, although the metal it is made of does not heat particularly evenly. Cutting the bird in half lengthwise through the breast bone will allow you to cook it in 2 smaller kettles by dividing the other ingredients. Put the turkey and the giblets (except the liver) into the kettle and add the water. Add all the vegetables and spices. Cover and bring to a boil. Reduce the heat and simmer about 15 minutes per 1 lb. turkey. Cool the turkey in the broth for 30 minutes then cover and place in the refrigerator overnight.

The next day, take the turkey from the broth, and remove the skin. Remove the meat from the bones, starting with the large pieces of breast meat. Wrap the meat well and either refrigerate or freeze. A whole breast will slice beautifully, and the other meat can go into casseroles, sandwiches, soups, etc. You could return all of the bones and skin to the stockpot and simmer for 4–6 hours to get additional broth. Chilling will allow the fat to rise to the top of the broth; remove it before storing broth in refrigerator or freezer.

**ROASTED TURKEY** You must first figure out how you're going to get it into the oven, if you let it grow to a humongous size. Then rub the outside with oil or butter, stuff it if you want, and truss. It will cook faster if you don't put the stuffing into the bird, but bake it separately. But a problem with roasting turkey is keeping it from drying out. So it helps—and is delicious—to have a nice moist dressing inside it, and gravy to pour over when you serve it. For dressing, giblet gravy, and seasoning, proceed as you would for chicken, except everything is on a larger scale.

Set the bird on anything that will hold it, fit into your oven, and won't burn—like a cookie sheet. Set it down on top of a couple slices of buttered bread to keep it from sticking to the pan. Some cooks roast them breast down, but I prefer breast up. Some cooks, especially for a very large bird, bake it for an hour and a half, take the bird out, turn it over, and continue baking with the other side up. But I think that's unnecessary extra struggle.

**Roasting Temperatures and Times.** The following baking times tend toward the maximum rather than the minimum. It's hard to be precise because you may have started with the bird more or less chilled from the thawing, and ovens vary in their true temperatures, and stuffings vary in their density and temperature. So your bird is quite likely to be done an hour or so sooner. That's okay. It's easy to keep a roasted turkey warm in the oven before dinner. It's impossible to hurry one up while your hungry would-be diners are waiting for it to finish baking. Note also that fresh turkeys take a little longer to roast than ones that have been frozen—about 5 or 10 minutes longer per pound.

Roast at 425°F for half an hour, then finish at 325°F. Continue roasting until it has turned a nice shade of brown. The larger the turkey, the more baking time. With stuffing, figure on cooking a 6-lb. turkey, 3–3 ½ hours at 325°F; an 8-pounder, 3 ½–4 hours; a 12-pounder, 4 ½–5 hours; a 16-pounder 5 ½–6 hours; a 20-pounder, 6–7 hours; and a 24-pounder, 7 ½ hours.

**Eating Up a Whole Turkey.** This can be a real challenge for a small family. This is not a one-time happening, so you might well do some advance planning. Figure on roast turkey for its first appearance at the table. Serve it with baked or mashed potatoes, stuffing, and maybe a green vegetable, hot giblet gravy, homemade bread, and dessert. A real feast. Now it's not so simple. For the second appearance you could offer turkey a la king with a "white" sauce that substitutes chicken broth for the milk. Add pieces of turkey, pimento, and peas and serve over toast. Next time have turkey sandwiches with mayonnaise, salt, pepper, lettuce or whatever. Or turkey (taco) salad. Or turkey pizza. (Marinating leftover turkey in olive oil and rosemary prevents drying.) Or turkey and rice. The last time serve Turkey Bone Soup.

**LEFTOVER TURKEY AND RICE** Spread out 4 c. cooked, chunked turkey meat in a large skillet or shallow baking pan. Mix together salt and pepper to taste, ½ c. honey, ½ c. prepared mustard, 1 t. curry powder, and 1 t. turkey drippings from the roasting. Pour the sauce onto the turkey meat and mix it all together. Heat thoroughly on top of the stove, stirring as needed, or bake until hot (about 30 minutes at 350°F), stirring once or twice during that time. Let your family spoon this over cooked rice. A sprinkle of chives over all adds more color and flavor.

**TURKEY BONE SOUP** Break up leftover cooked turkey when you're seeing more bony skeleton than meat on the carcass. Put bones, meat, and your leftover stuffing along with carrot chunks and some onion and maybe celery into a kettle with plenty of water. Add a few peppercorns, salt, and a bay leaf. Cook an hour or until you can get the remaining meat easily off the bones. Then sort out and discard the bones. Now add about ½ c. rice or barley, and cook on low heat until the grain is ready.

**CANNING TURKEY—OR RABBIT, OTHER SMALL GAME, OR OTHER POULTRY** Cut the bird up enough to be able to precook it in a big pan or pressure cooker. Cook until you can easily remove all the bones, then discard them. Place the hot meat pieces into quart jars. Add 1 t. salt per jar, put
on lids, and process at 240°F (10-lb. pressure) in a pressure cooker for an hour and a half. When the cooker is opened, remove jars and fully tighten lids.

**CANNED TURKEY SOUP STOCK** The water that you precooked the turkey meat in is a good basic soup stock. Cool and skim to remove the fat. Pour stock into pint jars. Add 1 T. barley, rice, or other soup-grains to each jar, plus small pieces of the gizzard and heart and marginal bits of meat scavenged from the bones pile. Do not add liver. Fill to within 1/2 inch of the top. Put on lids, process for 35 minutes at 240°F (10-lb. pressure). Tighten lids.

Turkeys never have to ponder the mysteries of life and love. Reality can be harsh and hard, full of pain you can’t escape—but it can also be joyful and marvelous, like falling in love. You can love your plants and animals and feel in control. When you fall in love with another human being, you must trust them to care for you. You’re no longer in total control (although I’ve seen some people manage to come darn near it—loving and being in control of their own life and now their partner’s also: a stressful lifestyle). There is a time to love, when it’s very hard not to love. Yet you could resist. Would it be better to say no this time and hope for a better match next time? There will be another chance.

**THE WATERFOWL: DUCKS AND GEESE**

Many of the principles of waterfowl care are the same as those for chickens and are covered in that section. This section covers cases in which duck and goose care are the same for each other but different from that for chickens. Following this combined section, there are individual duck and goose sections.

In general, ducks are small waterfowl, and geese are big. The Muscovy is a bird that fits into both categories. I’ve seen it grouped with the geese, but it’s more often categorized with the ducks, and that’s what I’ve done, too.) Ducks and geese often form strong attachments to their owners. On the average, ducks are noisier than geese, especially White Pekin females. Muscovy ducks don’t quack, but they do hiss like a goose. The waterfowl are actually harder in resistance to poultry diseases than chickens and seldom suffer disease when kept in small flocks. However, when waterfowl are raised in very large numbers in a small area, they, like all animals under those conditions, are more likely to be affected by disease. Egg-specialist duck breeds lay as many eggs as egg-specialist chicken breeds. Duck and goose eggs are 14.5 percent fat, as compared with chicken eggs, which are 10.5 percent fat; in both cases the fat is located in the yolk. Some shade and shelter are preferable, and fencing will keep birds in and predators out.

To join the American Pheasant and Waterfowl Society ($25 annual dues and you get the APWS Magazine with classified ads, breeders directory, annual convention, lending library, free "wanted" ads, etc.), contact Lloyd Ure, Secretary-Treasurer: 715-238-7291; fax 715-238-7623; W2270 US Hwy. 10, Granton, WI 54436; [lloydbevbirds@tznet.com](mailto:lloydbevbirds@tznet.com); [www3.upatsix.com/apws](http://www3.upatsix.com/apws). Another good waterfowl website is [members.tripod.com/~QuackersHomePage/index.html](http://members.tripod.com/~QuackersHomePage/index.html) or [QuackersHome.com](http://www.quackershome.com).

**WATERFOWL BREEDERS:** Also see “Places to Buy or Order Poultry” under “Chickens” in this chapter for other waterfowl addresses, because most chick hatcheries offer some waterfowl.

*Clearview Hatchery* offers a free catalog: 717-365-3234; Gratz, PA 17030.

*Johnson’s Waterfowl* offers 21 breeds of ducks and 12 of geese: 218-222-3556; 36882 160th Ave. NE, Middle River, MN 56737.

*Metzer Farms* sells ducklings, goslings, guineas, pheasants, wild turkeys; 35 breeds in all; also equipment. Free catalog: 800-424-7755; 831-679-2355; [metzinfo@metzerfarms.com](mailto:metzinfo@metzerfarms.com); 26000 Old Stage Rd., Gonzales, CA 93926; [metzerfarms.com](http://www.metzerfarms.com).

*Phinney Hatchery* offers ducklings, goslings, etc. Free price list: 509-525-2602; 1331 Dell Ave., Walla Walla, WA 99362.

*Windchime Lakes*: Dan Bishop is a swan specialist. Contact 402-359-4444; 4820 Dodge St., Omaha, NE 68132; [swan@swan.net](mailto:swan@swan.net).

**TOE-PUNCHING:** Because they have webbed feet, and because their feet have no nerves, ducklings and goslings are sometimes marked to record sex, breed, genetic category, etc., with small holes punched in the web between the claws, or with a certain number or location of notches cut into the edge of the web between toes: for example—1 hole for a goose, 2 for a gander.

**Of Water and Waterfowl**

For best health, these birds need at least to be able to get their heads and feet wet. You don’t need a pond to raise waterfowl, but they do like at least a small tub in which to splash. Frequently changed swimming water for them in something like a shallow hog pan or a child’s swimming pool can be sufficient. Adults can be kept in a pen with just a bucket or tub of water that is refilled a couple times a day. A water container with a float valve works well—sunk into the ground so that the edge is level with the ground, it is perfect. Or you can make a cement pool, maybe 3 feet across and 12–18 inches deep. Put gravel around the edge of the swimming pool to keep the area from being muddy.
and help keep the water clean.

Once started, ducks require little commercial feed if they have enough foraging space, eating a combination of grain, green stuff, worms, and bugs in season—grasshoppers, caterpillars, crickets, and slugs. Geese can live on grass, but you may not want them in any lawn area since their droppings are very messy (not a treat for children’s bare feet). Both ducks and geese are among the most efficient animals at converting feed to meat, and they tend to get fat if overfed. Ducks are ready for the deep freeze faster than geese: 8 weeks of feeding yields 7 lb. of duckling; 13 weeks of feeding yields an average 12 lb. of young goose (live weight). These are the healthiest of the fowl (with geese being even harder than ducks) and are rarely afflicted with diseases or parasites, and they require little or no shelter, even in winter.

**Of Water and Mating:** In such a pool as described above, the waterfowl that can’t mate effectively on land can accomplish what must be done. The heavy duck and goose breeds—Giant Toulouse, Aylesbury, Rouen—need swimming water in order to mate successfully. Wild ducks and geese mate on the water. Domesticated birds closely related to the wild also need water to mate: Mandarins, Wood Ducks, and Canada geese. Ducks or geese that are sitting on a nest always need access to water; a shallow pan of it can suffice. The birds must depenn their feathers daily to add required humidity to the eggs’ environment.

**Pond Life:** If you have a pond, about 25 ducks and 6 geese is the maximum population per acre of water surface that you’d want to carry. You wouldn’t want them swimming in a place you use for people swimming because they poop copiously into the water—which is good fish food—and on the banks of it. They like to eat water lilies and small frogs. A reasonable-sized flock of ducks will clean up a pond full of green filamentous algae because their droppings encourage microscopic pond life that hold back the algae. Those droppings can also be food for certain species of fish. Ducks eat water weed roots and will clear the shore of a pond, widen and open up streams. Waterfowl do not effectively control tropical water plants such as water lettuce and water hyacinth. An overpopulation of ducks will build-up. Waterfowl that haven’t been able to dip their ends into water to rinse it off sometimes develop sore or sticky eyes, an infection that may cause permanent blindness.

Grossly dirty water can also cause sticky eyes in your waterfowl. Treatment for sticky eyes is astringent eye ointment.

**Waterfowl on Saltwater:** Ducks thrive in saltwater too. But if your wetlands are salty, be sure you supply adequate amounts of fresh water for drinking.

**Raising Young Waterfowl:** It would be wise to start with only about a half dozen birds, at least until you better understand what you’re doing and how the fowl are going to fit in with your environment and lifestyle. Don’t overcrowd your waterfowl. Consider that you need about 13 square feet of housing and about 40 square feet of run area for 1 goose or 2 ducks. You can mail-order ducklings and goslings, but these larger birds are not cheap. Ducklings cost about $3 each. The care of young ducklings and goslings is distinctly different from that of chicks in some important ways, although the basic principles are the same. Or, if you have breeder birds, you could let them raise the babies.

**Incubating Waterfowl Eggs.** Use all the guidelines for chicken eggs-in-waiting, plus: In the incubator you’ll want holders suitable for eggs larger than chicken eggs. Serious waterfowl hatcheries use incubators that are specially adapted for hatching these eggs. Set the temperature control for 99–100°F for a forced-air style incubator, 101–102°F for a still-air incubator.

**Incubator Moisture.** Waterfowl keep their eggs very moist. In a dry climate, even in an incubator, high humidity is not good enough. There are several ways to supply this extra humidity: Give a light spraying of lukewarm water to the eggs once a day. Or, do as a friend of mine does and remove duck and goose eggs from the incubator twice per day and dunk them in warm water. The way the parent bird keeps them wet enough is to get off the nest, get her breast feathers all wet, and then return to the nest. Finally, you might enhance the water pan’s evaporation ability by resting a piece of sponge in it that rises a couple inches out of the water, and each time you turn the eggs, spray them gently with warm water.

**The Hatching.** On the 25th day quit turning the eggs, but keep on dunking or spraying the water until the ducklings pip their eggs. The pipping should take 28 days after incubation began for most ducks, but Muscovy eggs require 35 days. Give 1 last spraying and/or dunking when the pipping occurs. Then you hope for the best. Day-old ducklings can be vent-sexed in a manner similar to chicks.

**Brooder Shelter:** Although they are harder than chicks or poults, ducklings and goslings must also be kept from chilling for the first month. Their shelter can be simple, but it should be dry and not drafty. The flooring of your brooding space can be wood, concrete, or dirt. An 8 × 10-foot southeast corner of a barn would make a fine spot in which to start ducklings. If you are using a brooder setup that was designed for chicks, you can expect that it can handle half as many ducklings as it could chicks, or a third as many goslings. Plan for about 1–1½ square feet of floor space for each duckling or gosling, increasing the space to 2½ square feet for each bird at 7 weeks. Waterfowl grow faster and develop warm feathers earlier than baby chicks. Some people use unheated boxes insulated with 2–4 inches of rags, straw, sawdust, or grass, covered with burlap, with a small entry hole in the side. The young
ducklings' body heat can keep them warm in this close environment. Although this is less expensive than a heated brooder, you have to be careful that the babies don't suffocate.

**Brooder Heat.** If you are using infrared brooders, every 25 goslings or 30 ducklings should have their own 250-watt heat lamp. You'll want to raise the heat source a few inches higher than what you use for chicks for these larger babies. Having enough separate heat sources for the number of young birds eliminates overcrowding around the heat source, which could result in smothering. Leaving the light on all night can also discourage crowding. Try for a starting temperature of around 90°F at the edge of the heat circle. Each subsequent week, reduce the heat 5 degrees until you get to 70°F Brooder temperatures that are chronically too high cause the birds to grow and feather out more slowly than normal. Panting birds are a good indication also that the heat is too high. Huddling birds are not warm enough. After 4 to 6 weeks you can turn the heat off, unless your outside temperatures are outrageously low. By 4 weeks of age ducklings have begun to grow a covering of heavier feathers for their backs and can go outside in the daytime in good weather. As early as 10 days, goslings are ready to abandon the brooder.

**Duck-Raised Ducklings:** For those ducks that make good mothers, the ideal circumstance is to let the mother duck manage her own ducklings. Duck-raised ducklings learn faster to forage for themselves and how to swim. There are, however, some cautions. Ducks with broods should be separated from the rest of the adult flock and confined at night until the ducklings are 6-8 weeks old. Even 2 hens with broods should be kept separate, as they often react with hostility toward any but their own ducklings. If you are planning on hatching more eggs than you have brooding mothers, you can incubate.

**Waterfowl Mothering Chicks.** If you give a duck chicken eggs to sit on, she'll do a good job, but once the chicks hatch out, it can be a very risky business. Most owners take duck-hatched chicks away and brood them separately, because the duck mother may lead her chicks to the deep water, and the chicks are likely to get wet or drown as she goes about her necessarily sloppy way of drinking. You can have chickens or turkeys set on duck eggs, but if you do, be sure to confine the foster mothers for the first 2 weeks so they won't desert their charges. If you set duck eggs under a chicken hen, keep the number down to 8-9. Unless a chicken has set and hatched ducklings, don't trust ducklings to her care.

**Of Ducklings and Goslings, Food and Water**

Strangely enough, you have to be just as careful to keep these babies dry as you do baby chicks, at least for the first 2 weeks. Chilling after becoming wet is the most frequent cause of duckling deaths. Waterfowl raised by their parents learn to swim early, but hatchery goslings and ducklings can't swim until they feather out at about 6 weeks. Even after they can swim, young birds can tire easily and drown, so be sure they can easily get out of water containers and ponds by providing a ramp or gently sloped banks.

**DRINKING WATER:** Always keep drinking water available, and in generous quantities. When mail-order babies first arrive, dip their bills, one by one, in lukewarm water several times. Then dip each bill in the feed trough.

**NOTE:** Make sure they drink before they eat, or they can choke on the dry stuff. Be sure the water you supply at all times is deep enough for them to get their entire head into. They need more water than chickens in order to clean the dry feed out of their breathing holes, located in the upper bill near the head.

**Drinking Containers.** A suitable water container for young waterfowl could be a narrow trough about 2 inches deep by 1 inch wide. They would be able to submerge their heads in that. (Young Call ducks have a tendency to chill, soak, or even drown themselves in their water containers and need special supervision.) Ducks can be extremely messy with their feed and water. Use a watering device that they can get into and splash from because you want to keep your brooder house floor dry. A piece of clean burlap bag spread over the floor surface would be a good beginning flooring. Or, if they're on a cold floor, cover it with a litter layer—about 4 inches of shavings, ground corn cobs, peanut hulls, peat moss, or almost any other sort of organic dry litter. If places on their flooring do get wet, shovel them away and add dry material. Or move the water pan frequently and stir the litter as needed to keep the top reasonably dry.

**NOTE:** Do not put newspapers down for water-slopping babies. Newspapers become a slippery surface, which can cause the birds to become spraddle-legged and crippled.

**Starter Food:** For goslings and ducklings, food should be ready when they arrive. Keep food in front of them all the time. But fill their feeder only half full to prevent waste. They'll also need very small gravel for their gizzards. Because of the shape of their mouths, you can't use chick feeders for these birds. To start with, offer food in small box tops scattered near the heat lamp until they learn to eat. Later you can supply food on rough paper, like the bottom of open grocery store bags. Don't feed them on smooth paper; they can slide around on it and get hurt. Older birds can be fed from pans or troughs or from self-feeders that hold pellets and have small openings.

**Home-Grown Starter Food:** Commercial chick
feed is not good for young waterfowl. The protein content is too high, and some of the medication in such feeds can harm them. I worked up the following system to start goslings on home-grown food, and they liked it. I suppose this sounds bizarre to people who are used to feed that comes from the store in sacks. All I can say in my defense is this: they thrived. I fed them 3 times a day, all they would eat of the following: For breakfast, cooked oatmeal covered with a little water. Lunch: scrambled eggs covered with a little water. Supper: homemade whole wheat bread covered with a little water or milk.

I supplied greens at all 3 meals—not grass or tough stems at the beginning—but very tender green leaves. They enjoy finely chopped onion greens and dandelion greens and practically any others that are fresh. Ducks thrive on watermint and cresses. I cut the greens up for them with a knife or scissors. If you are supplying water in a trough, sprinkle the green bits in the water. After the first week, I offered more and more greens. Young waterfowl won't pick each other to death, but, if short of green foods, they may pull and eat each other's feathers, which isn't very good for either the eater or the eaten.

I gradually shifted from cooked food to grain. Their bills were stronger and they could manage weeds better. In good weather they went outside to pasture with my daughter as goose girl. Grass is a very important part of a gosling's diet. Protein is the eggs-and-milk part of their diet. Feed about 20 percent protein. At 2 weeks on a home-devised diet, supply or allow them to get some grit. They're well fed if they have 2 or 3 feedings a day of all they can consume in 5–10 minutes.

**Commercial Starters:** If you can't get a duck-starter ration or goose-starter (either one would be fine for either species), you can use unmedicated chick, turkey poult, or game-bird starter for the first week or two (then switch to grower feed) if the feed is also recommended for ducklings and goslings. That's because some types of chick starter and growing feeds contain drugs for coccidiosis control that can cause lameness or even death if fed to the water birds. Yet some folks have fed medicated starter and layer feeds to waterfowl and gotten away with it; maybe they were feeding starter medicated at a low level. Crumbles are the best consistency. Fine mash feeds are more likely to cause the birds to choke.

After 2 weeks for ducklings, or 4 weeks for goslings, gradually shift to a pelleted grower ration. Ducklings and goslings being raised for the commercial market are usually given turkey finishing rations or some similar food their last couple weeks. By using genetically fast growers like the White Pekin, placing high-protein commercial rations constantly before them, and ensuring the inactivity of confinement, you can have freezer-ready ducks at 7 lb. in 7 weeks. Goslings, so provide them with some small pen within the coop that the chickens can't get into.

There are 3 distinct schools of thought on the subject of shelter for waterfowl. One is no shelter at all, or only a windbreak of bales of straw. A second concept is shed-sheltering, allowing them a place with 3 sides and a roof, but an open front. The third concept is a complete dwelling—with or without attached pen or yard, in which they can be confined just at night or all the time.

**No Shelter:** Waterfowl always need access to shade, but once they are 6 weeks old they can do without other shelter (unless there is a long spell of chilling rain or stormy weather). By 8 weeks of age they can probably well take care of themselves. Adult waterfowl seldom require shelter. This is because their outer coat of closely packed feathers has been waterproofed. Ducks in the wild build their nests near water on the ground. A flock of ducks can do well and lay without formal houses or nest boxes.

Nevertheless, some fancy breeds are less hardy or less disposable than others, and some climates have worse winters than others. Ducks, who do not roost but sleep on the ground, have been known to become frozen to the ground by their own moist droppings. (Ducks that have access to open water may spend the night there.) Unconfined ducks (especially the breeds with poor mothering instincts) are likely to lay eggs all over the place—on the ground, even in the water. If you have foraging, unsheltered waterfowl, be vigilant against predators, keep them in the territory where you want them, and consider shelter at least from severe storms. If baby ducks are being raised by you or their mothers near any body of water that is halfway natural, you may take some hard losses. Bullfrogs and other critters like to eat baby ducks. You might do better bringing the young ones into the house to raise until they've attained a good size.

**A 3-Sided Shelter:** Some waterfowl raisers prefer this system that protects the flock from wind and rain but otherwise allows them freedom. Waterfowl dislike wind, and such a shelter (built broadside against the prevailing wind direction) can at least protect them from wind and precipitation. Waterfowl like fresh air and dislike poorly ventilated quarters. They are nervous and like to be able to see what is...
going on about them at night. And if crowded into a small house they may startle and pile in a corner. There's no need to make the 3-sided (with a roof) shelter any taller than the birds it is designed to protect (which saves on lumber). Waterfowl confined indoors a lot may not be as healthy as those allowed to live outdoors. Like Chinese geese, African geese are susceptible to frozen or frostbitten knobs (on their beaks) in winter and would be better off with at least this minimal shed-type shelter. If it will be below 20°F; these knobbed fowl need even more shelter to protect their knobs. If, however, the knobs do freeze, it merely results in a discoloration of the bill and knob, which will return to normal by the following fall.

**Total Shelter:** Waterfowl can be housed just at night or all the time. Ducks adapt well to housing at night only because their egg-laying habits are so precise (almost all lay their eggs before 8am, 9am for sure), and because their habits are so regular (they can be trained to return home to be fed and be confined at a precise time). Duck and goose owners in areas where night predators such as rats, raccoons, skunks, weasels, and ferrets are active prefer to confine their birds at night—or even all the time—in a building similar to a chicken house. Call, Mandarins, and Wood Ducks are not as hardy as the others and do need winter shelter, though they can go outside and get in the water at 40°F and warmer. African, Chinese, and Egyptian geese benefit from winter shelter (in temperatures below 20°F). Ducks will start laying earlier in the year if housed; it does not make any difference to geese. If you do confine ducks at night, be aware that they are nervous creatures and can damage themselves by panicking and running in circles. If you leave on a low-wattage night light, you will minimize this danger.

Waterfowl housing can be small and portable and frequently moved to keep the ground underneath tolerable. Such housing may be set into sizable, well-drained, well-shaded fenced runs that (ideally) have access to clean, running water. Small ducks such as Calls, Indias, and Mallards can be raised sun-porch-style. A graveled duck yard that can be cleaned when hosed daily at high-pressure and is sloped somehow to drain, can help keep clean the quarters of a large spring flock being raised for butchering. Without gravel or concrete, you risk a sea of mud.

**Totally Confined Waterfowl:** Allow 4 square feet of floor space per duck for ducks that are let out during the day. If ducks are kept confined at all times they'll need 6–8 feet of floor space per bird. If you limit the total number of fowl and have a loose, deep (1-foot) litter layer, you can keep them confined and it can be manageable. Large (15 inches square), shallow nesting boxes located on the floor in the corners of their housing will attract the egg-layers. Confined ducks need excellent ventilation in hot weather and plenty of water, always. Shutting them up together with chickens can be a problem if there are too many birds for the space, because ducks have such exceptionally copious and liquid droppings. If the waterfowl housing is to be permanent, the ground underneath should slope to one side for drainage and the floor should be made of pea gravel, which can be hosed and drained, or concrete with a center floor drain. Waterfowl kept completely on hard, dry ground, however, can sometimes develop bumblefoot, which is a warty local infection of the foot that causes limp-

**Of Flying and Waterfowl:** The flyers are Muscovies, Indies, Calls, Mallards, Canadas, and Egyptians. To keep these at home you'll have to clip the long feathers on 1 wing side with heavy scissors when the feathers first develop and after each molt, if you keep the birds that long. Or you can "pinion" them—which means to amputate the tip of the wing (the part below and outward from the "claw" extension just beyond the last wing joint) on 1 side. The pinioning operation is done when the duckling or gosling is a week old. The cutting is done with a sharp knife, razor blade, or debeaking machine. And use 4-foot-high fencing.

**About Feathers**

The feathers and down of geese and ducks can be used to make pillows, comforters, insulated jackets, and other outdoor clothing, and you don't always have to kill the birds to get their feathers. In the spring, geese grow lots of lovely little feathers and then pull them out themselves and use them to create wonderful downy nests. These goose feathers are very soft and warm. Duck feathers have the problem of an odor which is difficult to remove completely. Nevertheless, either duck or goose feathers are softer, fluffier, and more moisture-proof (so they don't absorb sweat) than chicken feathers. A general rule is that the feathers from 3 geese or 5 ducks will amount to 1 lb. of feathers. You can sell goose feathers if you have enough to make it worthwhile. Mature ducks have more down than young ones and also more down in the fall when cold weather has set in. So what human beings might try to do is share in the feather crop that's going to come off anyway.

**Live Plucking:** In Colonial days, goose feathers were obtained 2 (spring time and harvest time), 3, or 4 times a year, by stripping them from the live birds—except for the quills, which were used for pens and were never pulled but once from a goose. The first time is when the geese are between 9 and 11 weeks old—when they start molting. After that they are plucked about every 8 or 9 weeks. The best
feathers of all, however, are said to come from geese that are
fully grown, from October on for spring-hatched geese. In
Europe and in some areas of Canada such live plucking is
still done. But times aren’t so grim now, and I don’t know
anybody who plucks their geese until after they’ve been
butchered and scalded.

Live-plucking causes momentary discomfort and stress
to the bird and does reduce egg productivity. But if you
must try this, wear old clothes and tie a cover over your
hair, because the down flies everywhere. Have paper or
cheesecloth bags and string ready before you start. Pull a
stocking over the bird’s head to keep it from biting. Pluck
the down and short body feathers in a season the birds
would normally be shedding them, at which time the feather­
ers release a little easier than at other times. Pull the feather­
ers the “wrong way”—against the grain, firmly and quickly.
In small pinches, pull the feathers from the underside of the
bird, removing not more than half the feathers from any
area. Don’t leave bare patches and keep the plucked birds
from swimming for a couple weeks so they can regrow suf­
cient feathers to stay water-proof. They say the birds get
used to it, but it seems to me that the small gain in feather
quality is not worth either the stress to your birds or the
extra work for you.

A good further source is “Producing Your Own Down,”

DRY-PICKING A DEAD BIRD: If you’re planning to save
the feathers, have bags ready before killing the birds. Pull in
the direction they grow. Working over a large garbage bag
or in a confined area will keep the down and small feathers
from floating away. Be careful to free the feathers of any skin
or flesh that adheres, or they will be tainted. Pull the large
flight feathers first, then the outer layer of feathers second,
and finally pull the soft under-layer of down. If you want to
get some stuffing from the feathers over 2 inches long (es­
pecially the large wing and tail feathers), cut with a scissors,
or strip off and discard the quill. But most people don’t
bother with that. After the feathers are taken off the bird,
remove the down by brushing the body with your hand
moistened in water. The bags full of feathers can be closed
at the top with string or staples or folded tightly. The next
step is to clean and dry the feathers. (See “Cleaning and
Using Feathers” under “Chickens.”)

CHICKEN-STYLE SCALDING AND PICKING: This, of
course, you do to a dead bird. In a large container, heat
water—enough to cover your bird completely—to 140°F or
higher. Add a little detergent (or shampoo) to the water and
stir it in—this is so the hot water can get past the bird’s
preening oil. Holding the bird by its feet, submerge it com­
pletely and swish it forcefully around for about 1½ minutes
(much longer than for a chicken)—until the hot water has
penetrated the bird’s skin and done its job of relaxing the
feather follicles. Older birds may need more time. Then,
right away pull out the feathers, big ones first. If you have
trouble getting them out, your water wasn’t hot enough
and/or the bird wasn’t in there long enough. (Try it again.)

WAXING METHODS: The disadvantages of these meth­
ods are that you need to buy and melt the wax, it ruins the
feathers, and it takes a lot of wax to do the job—especially
on a goose. Nonetheless, some growers think it’s easier this
way. Use paraffin, a combination of half paraffin and half
beeswax, or a commercial mixture that you get from a poultry
supplier. The wax takes out the feathers easiest immedi­
ately after butchering. The wax should be heated to between
160 and 200°F in a double boiler. Higher-temperature wax
penetrates better but doesn’t adhere in as thick a coat. A wax
coat that’s overly thick may not cool and harden as well.

NOTE: Do not heat the wax by itself. Do not let the double
boiler run out of water.

Hold long-necked birds by the head in one hand and
the feet in the other to dip them. The dryer the birds when
dipped into the wax, the better the wax will cling to the
feathers you’re trying to remove. You can keep dipping and
stripping until you’re satisfied. Commercial growers scald
and pick first, then dip and strip to whatever’s left over.
The wax can be recovered by heating (in water) to melt it
and then straining or screening out the feathers, etc. It can
be reused for this purpose again and again.

HOT WATER/HOT WAX/COLD WATER: For this
 technique you need 3 pots, 2 hot and 1 cold. You dip the
dead bird first in hot water and do a full chicken-style scale,
then dip the bird in hot, melted wax. Then dip the bird into
cold water to solidify the wax. Then you can strip wax,
feathers, and pinfeathers all together from the bird.

COMBINED HOT WATER/HOT WAX-HEAT: Save
your scalding water. Add paraffin to the hot water, which
will melt and form a thick floating layer on the top of it. Put
the bird into the hot water and swish to scald the feathers
loose. Then pull it out very slowly so that a layer of the wax
will cling to all the feathers. Allow the paraffin to solidify
and then pull wax and feathers away.

Once the feathers are off, singe off the filoplumes (the
remaining long, hair-like feathers) over an open flame of
alcohol, and cut off head and feet at the first joint. Some
people like to skin the carcass to remove all signs of feather­
ers, but this can cause the meat to be dry and less flavorful
when it’s cooked.

Cleaning Ducks and Geese
Remove the oil sac on the tip of “the north end going
south,” including all the yellow oil-producing area around it.
That’s where birds get oil to preen themselves, and that
of water birds is strong tasting enough that it would be a
problem to leave it on. Clean as you would a chicken. The
esophagus and windpipe of ducks may require some force
to remove.

Of Ducks in Particular

DUCK FEATURES: When the duck preens, it spreads the
oil from an oil gland at the base of its tail, over its feathers.
A layer of insulating down under larger contour feathers
that are lubricated with this oil enables the duck to swim in
near-freezing water. Even the webbed feet are made to with­
stand cold because there are neither nerves nor blood in
them. Most domestic breeds are earthbound, but Mus­
covies, Calls, East Indies, and Mallards can still fly to some
degree. Ducks can live up to 30 years; however, few make
it to that age because their ability to produce eggs drops off
after 3 or 4 years. If you are buying adults for breeding stock,
choose birds 6–7 months old with evenly colored bills and
legs, and make sure they are healthy. The male duck is
called a “drake.” The female is called the “duck” (which,
of course, also means the species in general) or “hen.”
**Duck Temperament:** Of all the varieties of poultry, ducks—male and female alike—are the gentlest and least likely to act aggressively. Drakes seldom fight unless females are present. (This might be an incentive for you to choose them if you have small children.) Ducks are notoriously nervous and noisy at night and will make a commotion over the slightest deviation in their environment's characteristics, benign or dangerous. Because ducks are so nervous, announce yourself when you are coming to them, move slowly, and talk to the birds to calm them. If a duck does display aggressive activity, it is best to remain calm and ignore the behavior.

Ducks tend to be either good egg layers or good meat producers. Meat producers are calmer, easier to confine, and grow faster and bigger. The feed conversion ratio for ducks is about 3.1, which makes them a good economical choice whether you pick a breed for meat or eggs. You may also want to consider the noise level, coloration as a defense against predators, and expense and difficulty of obtaining the birds. And then there are the eggs—meat combination breeds to consider.

**Ducks in Print:** *Raising the Home Duck Flock,* by D. Holderread (1978), is a helpful book. The *New Duck Handbook: Ornamental and Domestic Ducks* by Raethel Heinz-Sigurtd, translated from the German (1989), has everything about housing, care, feeding, disease, and healing, with a special chapter on commercial uses of ducks.

**Ducks for Eggs:** Don't buy ducks for eggs until you try eating duck eggs. Duck eggs have a ducky flavor, all the more so if the birds do a lot of scavenging in the bottom of a muddy pond. Also keep in mind the pollution problems of various bodies of water. So if you're going to let your ducks feed in water, be sure it's not polluted water. You can hide duck eggs in an omelet with chicken eggs and use them in baking. If you have trouble eating duck eggs straight because of the unfamiliar "strongness," make bread and custards out of them. Or, like the people in countries where duck eggs are a staple, you could get used to the taste and learn how to cook with them.

Becky Coleman of Charlo, MT, wrote me: "I kept Khaki Campbells for eggs once and found that, except for a certain toughness, they couldn't be told from chicken eggs. They had the run of the yard and a pond, but were mainly fed a chicken layer crumble. I wonder if the strong flavors people talk about come from what the ducks have been eating, rather than being intrinsic to duck eggs." Thank you, Becky! I haven't personally kept ducks for eggs, and there are real perils for me in passing on lore I've read and never experienced, so I appreciate it when somebody straightens me out. (The trouble with trying to cover everything in a book is that it's not possible for me to try it all myself.)

Duck eggs do not fry nicely by chicken-egg techniques—best to use a different process. (See "Frying a Duck Egg.") Incidentally, duck hens often lay more copiously if they haven't mated with drakes, and nonfertile eggs keep better than fertile ones. So if you need eggs in quantity, consider segregating your layers from your breeders.

**Of Duck Laying and Setting.** Light-breed ducks (egg breeds) will begin to lay at about 6 months of age. Heavy-breed ducks are mature and will begin to lay eggs at about 7 months. An egg-laying duck's commercially useful laying period is considered to be 3 seasons. Actually though, they will lay longer than that. Most ducks lay their eggs at night, so it's a good practice to confine them then. Ducks begin to lay in the spring, in the morning. It's customary to let them out after 10 am, by which time they will be done laying. You can maximize egg production by providing at least 14 hours of light (use a 40-60 watt bulb) daily. Some people leave the lights on all night, as it also keeps the ducks calmer. If you want a duck to go broody, leave her eggs and let them fill up a nest. Free-ranging ducks will build nests of twigs, leaves, grass, and their own down, on the ground. Muscovy, Indies, Calls, and Cayugas are likely to be good brooders. Cayugas are good at incubating goose eggs. Among the Blue Swedish, Aylesbury, and Rouen breeds, some individuals may be good brooders.

**Egg Breeds**

**Indian Runner.** There are many varieties of Indian Runner ducks of which the White Penciled, Fawn, and White are said to be the best egg producers (225—325 eggs per year). The Indian Runner originated in Asia (as did the rarer Bali to which it is related). Runners are a nervous, light breed (drakes are 4 lb. at butchering age, ducks are 3 1/2 lb.) that stand quite erect, nearly perpendicular to the ground. They can move quickly, which helps protect them against predators. Their feed-consumption-to-egg-production ratio is very good, and they lay equally as well as the other best duck layers—the Khaki-Campbell. And their eggs are larger. They are exceptionally good foragers but make poor mothers.

**Khaki-Campbell.** This duck is a quiet, healthy, good foraging, hardy breed that will continue laying in cold weather—as many as 300—325 eggs a year. The Khaki-Campbell duck is khaki with bronze highlights, has a green bill, and weighs only about 4 1/2 lb. They don’t go broody, and they are the least interested duck when it comes to swimming. Their eggs are creamy white and large, considering that this is one of the smaller breeds of duck—smaller than Pekins or Rouen. Khaki-Campbells were developed by an Englishwoman (Mrs. Campbell) out of Mallards, Indian Runners, and Rouen ducks. Crossbreeding has diluted many strains. To get a good egg-laying bird, be sure you get a Khaki-Campbell selected for high egg production. Authentic Khaki-Campbells are said to lay well 3—4 years and do well in winter, as long as they’re sheltered from extreme cold. Butcher young Khaki-Campbells at 4 lb. to get a meat that is lower in fat than most ducks.

**Welsh Harlequin.** These ducks are said to have laid as many as 300 eggs annually. Duck egg production of these egg-specialist breeds is right up there with the best chicken layers. It's interesting to note that, like the egg-specialist chicken breeds, the egg-specialist ducks are also lighter in weight, more high-strung in temperament, slower growing, and non-brooding.

**Meat Breeds**

**Aylesbury.** These ducks are a British strain considered by the English to be the prime meat breed of duck. They are noted for being less nervous than Pekins and exceptionally friendly toward humans. They are also less hardy. They have white feathers and skin and light orange legs and feet. Aylesburys eat grass quite well and will be ready for slaughter at 7 lb. at around 8 weeks. The males will grow to 9 lb., the females to 8. For breeding, use a single drake to 2
ducks and provide water for a mating surface. Aylesbury ducks are not the best egg-layers. You may get anywhere from 35 to 125 eggs a year. In pre-incubator England, broody hens were used to raise the Aylesbury young.

**Chinese White Pekin.** This is the most popular meat duck. The White Pekin is a blocky, extra-heavy duck, disease- and stress-resistant. The Pekin is probably the best bird to raise if your main interests are efficient meat production for home or market and white pin feathers. They are an extra large duck and grow very fast with an efficient growth-per-pound-of-food ratio (2½ lb. of feed required per pound of gain). The White Pekin can be ready to eat at only 7 weeks of age, weighing 6½–7 lb. The bird is then perfect for roasting (although fairly high in fat content) and is technically called a “duckling.” Adult Pekin drakes weigh 10 lb., hens, 9. The Pekins come in numerous different genetic strains, as developed by different competing breeders. In general, Pekin drakes are very fertile; the Pekins’ large, white eggs are quite hatchable; and 1 Pekin drake can handle 3–5 ducks.

Although they are high-strung and poor setters, freeranging pairs have been known to raise up to 20 ducklings a year. Don’t mate a younger drake to older ducks. Pekins are a poor choice for a foraging duck, and the females are noisy. The Pekin is considered a good layer—between 125 to 175 eggs per year, if they are well-managed, and so could be used as a meat—eggs breed. When Pekin ducklings are being raised on a commercial scale for meat (and not being kept for breeders), they are referred to as “green ducklings.” Green ducklings are kept confined to limit their exercise and kept under continuous light because that stimulates growth. Feed-conversion efficiency drops off after 7 weeks, and green ducklings are butchered shortly after, when their wing feathers develop. That’s pure agribusiness for you.

**Muscovy.** This is a large white or colored (depending on the variety) lean duck with well-muscled breasts. They often have a darkening, like a mask, around the eyes. The Muscovy duck is the only domestic breed not of Mallard derivation. They originated in South America, come in White or Colored, are slower growing than Pekins or Rouens, but are a first-class forager. Muscovies are also different from other ducks in the nature of their feathers, which are not as downy, are harder, and don’t oil as well as those of other ducks. They can actually drown, if unable to get out of the water for too long—especially heavy, long-winged males. The good news about Muscovy feathers is that they’re easier to pick than those of other ducks. An adult male can weigh 16 lb., but is more likely to be around 12. The much smaller females weigh 7 lb. Their meat is best if they are slaughtered before 17 weeks. The big ones can get quite fat if confined and overfed.

**Rouen.** This duck breed is large, like the White Pekins, which makes it a good roaster, and colored as prettily as the wild mallard from which it was adapted several centuries ago. Fly-tyers say that Rouen feathers make good trout flies and streamers. The Rouen doesn’t fly, and it has a quiet, friendly nature, which is nice if you have small children. They lay 35–150 eggs a year, some blue-green as Easter eggs, some creamy white. Rouens are slower growing than Pekins. They can be butchered anywhere between 2½ and 6 months. Rouens tend to stay very near home. Genetic Rouen lines vary in egg-laying powers—some are excellent, some poor. A reasonably light drake can take care of 4 or 5 ducks. Look for the trait of continuing to produce fertile hatching eggs past 3 laying years. Rouens do well on farm ponds and near wooded areas where a rugged duck with
good survival instincts is required. A 3-foot-high fence will keep Rouens (and most other non-flying ducks) in.

**DUAL-PURPOSE DUCK VARIETIES**

**Blue and Black Swedish.** This duck is rare in the United States (but more popular in Europe). It's a good insect-eater, lays 100–150 grayish white eggs a year, and has been said to be less prone to predator attacks because of its protective coloration. Crested drakes weigh around 7 lb., the ducks, 6 lb. They make good mothers and forage well.

**Buff Orpington.** These ducks are another rare dual-purpose (eggs and meat) breed. Drakes weigh 8 lb., hens 7. They may lay up to 250 eggs a year.

**Cayuga.** In the same weight class as the Swedish, Cayugas are a rare, rugged black American duck that can stand extreme cold very well, are good foragers, and lay 100–175 eggs a year. They are very quiet, but to avoid an unattractive carcass, it's necessary to remove the skin and pinfeathers.

**Call.** These are the best-known of the bantams. They are noisy little birds, either gray or white, favored as live decoys in England, where they originated. You'll need some patience to raise Call ducklings. They may do well on a diet of rolled oats and ground greens mixed in with their water. You can buy them from Shane Risner at Prickeree Pines Gamebird Farm: 616-868-6015; 12410 64th, Alto, MI 49302; X95risner@email.com.

**BANTAM DUCK BREEDS:** There are also the bantam duck breeds—the Call, the Australian Spotted, and the East Indie, all of which are excellent foragers and brooders. Most people keep them as novelties, as they do not produce eggs in great quantities (not more than 125 a year) and are comparatively small (usually under ½ lb.) for a good meat source. But their meat is of very fine quality, and they do lay well in the spring, if the eggs are gathered daily.

**Mallard.** These are relatively small (male, 2.8 lb.; female, 2.4 lb.) ducks that can fly. They prefer living where there's water to fly from and alight on, and they frequently dive and swim underwater. They are a wild species (believed to be the progenitors of many domestic ducks), are perhaps the best duck foragers, and are natural mothers. The Mallard does not fatten as well or ship as well as the Pekin, and they have gamey-tasting meat. The drake has dramatic feathers, while the female is a demure brown. Check with your state game regulatory agency before ordering Mallards—you might need a permit.

**Duck Food:** By the time they're a month old you can have your ducklings on a diet of grain, household scraps, and food from foraging. Liquid milk, mixed into their dry food at feeding time, and hard-boiled eggs can promote egg production and add shine to plumage. Adult breeder ducks being fed over winter can make it on a home-devised diet suitable for chickens. Ducks, like chickens, need calcium from some source for eggshell making and grit for their gizzards. Like chickens, they should not eat decaying vegetation or spoiled feed because they can get botulism poisoning from that. Most grains, including millet and rice, are popular with ducks.

**The Duck-Foraging Option.** Because of their foraging ability, ducks can be a bargain to raise, plus they help control bugs and slugs. At 4 weeks of age, your ducks can go on range. Foraging birds grow more slowly and are leaner at butchering time but will ultimately (in as many as 12 weeks perhaps) reach the same target weight. They are naturally good foragers and will hunt for and consume tender grass, clover, and green leafy plants in general—as well as insects, slugs, snails, and all their ilk. The most natural foraging territory for ducks is wet, low marshland. But a year-round large flock can make excellent use of a pond plus plenty of foraging space on shore. If given the opportunity, they'll eat weeds, berries, and seeds; will glean for fallen grain and fruit; do bug patrol in alfalfa fields and under rabbit hutches; and will clean out algae from ponds. Ducks enjoy Japanese beetle larvae. When liver flukes are a problem to cattle, ducks sent into their pasture will devour the snails that host those parasites and make the land safe for the cows again.

Ducks are not as good grazers as geese. Unlike geese, ducks must have young grass, so it helps them if you mow their foraging area to encourage new growth, or put some geese in with them. Some duck growers help by locating 1 or more electric lights near ground level, turning them on only at night. The ducks can then feed on the insects attracted to the lights. Foraging ducklings need adequate space for the number of them. Confined too closely they'll simply end up killing all vegetation in their space and creating a foodless mud hole. If you have wandering ducks and live near a road there may be a problem. Ducks travel together, they are fearless, and they don't move fast. Ducklings raised by a mother duck learn to find their own food very young.

By allowing your birds to forage you can cut back on the amount of their commercial ration or even completely do without it if you regularly supplement with such grain as cracked corn, wheat, milo, oats, etc., during seasons when they can't forage as well, or year-round if their foraging territory is limited.

**Commercial Food.** Ducklings do better on crumbles than mash, which they are very wasteful of. Ducklings need more niacin than chicks; lack of it stunts their growth and causes weak legs. So if your ducklings are not on a duck starter you could add a soluble vitamin from the feed store to their water. Their crumbles should be sprinkled occasionally with fine gizzard grit. Don't feed cracked or whole grains until the ducks are at least 4 weeks old. Once they get big, feed only once a day except in the dead of winter. Feed in the evening—about what they'll clean up in a quarter hour. Confined birds will need more feed, more often than foragers, such as twice a day. Confined ducks in winter
can get along on cheap grains supplemented with greens or quality hay. Don’t throw grain for ducks on the ground; offer it in a trough. Confined birds will enjoy greens or vegetable throwaway parts cut into small pieces and put into their water. Add ground eggshells to their food for calcium. Even if you’re feeding all commercial duck formula, it’s good to supplement with fresh greens.

**Duck Reproduction:** Ducks are sexually mature in 5–7 months. A drake in his first year is called a “drakelet,” and a duck in her first laying season is called a “ducklet,” corresponding to a pullet. Don’t raise male ducks or geese without the company of females. This can result in birds that bond to other males and will never mate with females.

**Telling Drake and Duck Apart.** With ducks it can be difficult to figure out which sex is which when you want to slaughter or sell some of your fowl and keep others for breeding. The Rouens can be distinguished by color, but most other domestic ducks cannot be sexed by color. You can sex ducks that are old enough for slaughter by voice. By then females will have developed a raucous, raspy-sounding call, whereas the male is comparatively hoarse and quiet. That doesn’t work with the Muscovies, but adult Muscovy males are considerably larger than females, so you can tell that way. Another way to sex mature ducks of all the Mallard-derived breeds (doesn’t work with Muscovies) is by tail feathers. Males have about 4 curly feathers on the upper side of the tail that form a loop back toward the bird’s head. Those are called “sex curls.” Females don’t have them. Duck hens with yellow or orange bills may develop dark spots on their bills when they begin to lay. An experienced person can identify the sex of a duckling by 2–3 weeks of age, by examining the duckling’s vent, but this requires care as ducks injure easily. To do it, you’ll need good strong lighting since the sex organs inside the vent are very small.

**Duck Mating.** Under natural circumstances, ducks mate on the water. The smaller breeds can also accomplish this on land as can smaller pairs of the bigger breeds. So pondless duck breeders select small drakes and large ducks. In general, heavy breeds should have 1 male to every 3–6 females. Light-breed drakes can service 4–7 duck hens. It’s smart to have an extra 1 or 2 avian studs for backup. If you are raising several duck breeds, keep them separated to assure the ducks injure easily. To do it, you’ll need good strong lighting since the sex organs inside the vent are very small.

**Hatchability.** Fertility is greatest when egg production is highest. Hatchability declines after the first few settings. It’s uncertain how long your drake breeder will remain fertile. One Runner drake is on record for having fertilized eggs 20 times, before 5 months for sure. After that the meat is tougher. In addition, ducks in molt are unsuitable for butchering. Pin feathers from the coming plumage make the plucking a formidable task. They molt at about 10 weeks of age, so butcher either before that or well after it. Or skin the duck.

**Catching a Duck.** First try to corral it in a small pen or fence corner so you won’t end up chasing it. With one hand right under the head, grasp it by the neck, and with your other hand, bring its body close to you, wrapping your arms around its wings so it can’t flap them. Ducks are easily hurt, especially their legs and wings, so you have to capture them without a big fight. Once you have hold of the bird like this, you can carry it with one hand under its body and the other holding its wings down. You can carry it with the head pointing to the back of you or to the front. Keep the bird away from your face and take special care with Muscovy claws.

**Killing a Duck.** Chop off its head. Or stun it with a sharp blow on the head and then stick it through the throat or just behind the eye with a narrow-bladed knife. Or hang it by both its legs and cut the throat back of its bill. Or use any of the same directions as found under “Chickens” in this chapter. Bleed the bird thoroughly. For picking directions, see “About Feathers.” A 7-lb. duckling will dress out to about 5 lb. of meat. For fried duckling some people prefer to peel off the skin and fat from the body and legs (the wings will be hard to do). If the duck is to be cut up (rather than roasted whole), any of the chicken methods can be used. Chill the carcass to 34–40°F as soon as possible.

**Duck Recipes**

**Frying a Duck Egg.** You can’t fry a duck egg the familiar, chicken-egg way and expect it to be tender. So lightly grease and heat a frying pan that has a lid. Break your eggs into it as for frying chicken eggs. Pour a little hot water about the edges of the eggs. Put the lid on the skillet and cook like that until the egg-white is firm (a few minutes). Serve promptly.

**ROAST DUCK WITH ORANGE JUICE** Rub the duck inside and out with salt and pepper. Put a whole onion and some chopped celery inside the duck or stuff it with a bread stuffing. Rub the outside skin with cooking oil or butter. Pierce the skin of a fat duckling in multiple places to allow the fat to render out. A duckling can be roasted at 450°F for 15 minutes, then at 350°F until done. A grown duck should be roasted at 350°F for about 25 minutes per pound, uncovered. When the skin is turning brown, begin to baste the bird once in a while with freshly squeezed orange juice or with the pan drippings. Optional: When the duck is done roasting, make a sauce by adding 2 T. flour to the drippings in the pan. If you burnt the bottom, pour the drippings into a frying pan and add the flour there. Add a cup each of water and orange juice. Don’t let it boil. Pour the sauce over the duck and garnish with orange sections.

**FRIED DUCK** Cook the gizzard, heart, neck, and rib bones the same as to make Seasoned Giblet Gravy (see recipe under “My Favorite Goose Recipes”). Or fry the first 3 along with the other pieces. If you saved the skin and fat from the body and legs when you were cleaning the bird, cut them into small pieces and render out the duck grease. Remove the cracklings. Beat 1 egg with a fork and add 3 T. milk, and salt and pepper. (You may need more dipping batter than this.) Dip each piece of duck into the batter, then roll
it in fine, dry bread crumbs. Brown the duck pieces in the rendered duck fat. When browned, pour off most of the fat, add 2 T. water, cover and bake at 350°F for 45 minutes in a Dutch oven. Remove cover during the last 10 minutes.

**Doris’ Duck Tip.** If your duck has a fishy or wild flavor, put the whole duck in salt water and add onions. Bring just to a boil and drain off water. Then prepare the duck as usual. Another lady told me her system was to stuff the duck with an apple and an onion, each chopped, and seasonings.

**Geese**

Although their primary value is as a meat bird—a good roast and *pâté de foie gras* (goose liver spread)—many people keep a couple of geese on their farms as pets. They act as “watchdogs,” honking loudly whenever a strange person or animal approaches. Although some goose lay fairly well, none will lay as well as the best duck and chicken breeds. On the other hand, some duck breeds are practically burnt out on laying after 3 years, and some commercial chicken breeds have a similar decline. Your goose is healthy, long-lived, and intelligent. They can thrive on no more than grass, can be a cash crop, and will lay eggs for an amazing number of years. (This perhaps can be an example to us on the benefits of plain living and moderation.) Most goose owners brood the eggs to maximize meat production and get table eggs from ducks or chickens.

**Geese in Print:** You’d benefit from reading *The Book of Geese* by D. Holderread. See also the section earlier in this chapter, “Further Duck and Goose Information.”

**Goose Breeds:** There are about 15 breeds of domesticated geese. Basically, the goose is raised for meat. Personally, I like goose meat much better than turkey. Whatever breed of goose you prefer, you’ll probably want to separate breeds or choose only one, because purebred geese are more marketable than those that are crossbred. An exception is the cross between the White Chinese gander and an Embden goose, a match that produces a goose that matures quickly to market weight.

**Chinese.** The closest thing to an eggs-and-meat goose breed is the White Chinese, which is almost as lovely on the water as a swan, gives noisy warning like a watchdog, and is a good forager and weeder. But they are less hardy than some geese in winter. The Chinese need shelter at below-freezing temperatures and heat at 20°F or lower. You’ll at least need to provide them a south-facing lean-to with a straw-covered floor. They are about half the size of the larger breeds—10–12 lb.—but still big enough for a Thanksgiving dinner, though connoisseurs complain that the Chinese’s carcass configuration is not as good as that of the larger breeds. But, the Chinese has a naturally leaner meat. The Chinese is the smallest bird and the best egg-layer among the goose breeds with quite good fertility. They produce from 40 to 65 eggs per year. Their eggs are large, white, and—like any other bird egg—just fine for cooking and baking. Some strains of Chinese have lost much of their broody urge; others still have it.

**Pilgrim.** This is an interesting, more recently developed breed (developed before the Second World War). The adult male is white with blue eyes. The adult female is gray and white with hazel eyes, which makes it easy to distinguish it from the male. Even day-old goslings are sex-linked to white and gray. The Pilgrim ganders are said to be friendly to humans and diligent in helping rear their goslings.
Pilgrims are cold-weather hardy, being able to do without shelter even in sub-zero weather. Pilgrims are smaller than Embdens, rating as a medium-sized goose, and weighing 14 lb. (goose) to 16 lb. (gander).

**Toulouse.** These geese have broad bodies of dark gray with white abdomens. They have reddish-orange legs and toes and orange bills. They are hardy in winter and are basically meat birds that grow fast—a pound or more a week for the first 12–14 weeks—and end up quite large. Toulouse are meat specialists. A Toulouse will have fall weights from 20 to 25 lb. Some Toulouse males grow quite large, up to 26 lb., if allowed to grow to maturity—which requires a full year. Toulouse geese have another advantage: they are the best goose for reproducing themselves, though the White Chinese and Embden geese also go broody very well. Although the female will lay about 25 eggs over a month, let her set on only 15. Giant Toulouse geese are an extra-heavy variant of the Toulouse that has the reputation of being a quiet breed, which may be kept unfenced because they won't wander far. Giant Toulouse geese will lay about 60 eggs per season, but hatchability runs only a little over 50 percent. The Giant Toulouse is said to be a relatively poor brooder and mother.

**Embden.** These geese are pure white, have very nice feathers, and are also hardy in winter. Like the Toulouse, they grow fast, although they are slightly smaller. The White Embden is the commercial grower's favorite. A gosling can go from 4 oz. at hatching to 11 lb. in 10 weeks. At the end of 12–14 weeks you can put 10–12-lb. birds in your freezer. Or let them grow longer. An Embden will have fall weights of 18–20 lb. Embden geese go broody very well and will lay between 35 and 40 eggs a year.

**African.** The African goose is not as heavy as the Toulouse or White Embden, but it matures earlier. It is light brown with dark brown accents and a black knob on its head. The dressed carcass is on the lean side, with an abundance of pin feathers. The African goose is a heavier relative of the Chinese, weighing 14 lb. (goose) to 16 lb. (gander) at butchering stage, a couple pounds heavier as a breeder. It also is a relatively good layer. African geese are significantly noisier than other breeds.

**Royal Chinese.** This rare breed is the largest goose in captivity. They can exceed the adult weight of most other breeds when they are only 10 weeks old.

**Buff and Sebastopol Geese.** Both are unsuitable for meat and egg production. The Sebastopol does have beautiful curly feathers, making it fine for showing or to keep for a pet.

**Canada or Wild Geese.** These are best left wild. Although you can keep one from flying off by penning it or clipping its wings, they give you neither plentiful eggs nor good meat and you need a permit to keep one.

**CARE AND FEEDING OF GEESE**

**Care of Goslings.** A good time to get mail-order goslings is when you have really warm weather. Order from the supplier who can get them to you quickest, and make arrangements to pick them up immediately upon arrival. Goslings will be about $5 apiece. An average family could eat 5 or 6 a year. (Plan to have that many disposable goslings a year once your flock gets going.) It's important to get your order in well before early spring, or the mail-order sources will be sold out. That's because a lot of these birds lay only in the spring, and if you don't get your babies then, you won't.

For more detailed information on raising goslings, see
chick-raising information under “Chickens” and the water­fowl section.

Feeding Goslings. Provide green grass to goslings as soon as they will eat. Although you can feed goslings the same diet as ducklings, you can also offer them bread or corn bread moistened with milk. Provide a fine grit. For the first week, feed them all they can eat in 15 minutes, 4 times a day. You can gradually reduce the number of feedings until the fourth week. By then they should be surviving well at pasture, supplemented with a little grain.

Pasture for Geese: When you are raising goslings, plan to provide them with green stuff, starting in the first week. Lawn clippings are fine for them so long as the grass hasn't had any chemical treatment. If the weather is mild, and you make sure they don't get either chilled or overheated, you can literally let them out to graze, from a few days of age on. This saves you a lot of money on other feed. The best kind of grass for them is tender and green, not long, dried up, and coarse. Same for weeds—they can't eat high, coarse weeds until they are older. Don't let them get rained on or be in wet grass until they are at least a month old, especially when the weather is cool. And if there is no natural shade for them, they'll need to be able to find shade under trees, or under a shelter—maybe a sheet of plywood nailed a few feet up on top of 4 corner posts.

At 5 or 6 weeks of age your goslings can survive entirely on pasture if they can get enough of it, although it's helpful to their diet if you continue the supplemental grain and/or pellet feeding until they're completely feathered. For serious, large-scale goose raising, goslings enjoy fields of ladino clover, other white clovers, alfalfa, and almost any grass such as bluegrass, orchard grass, timothy, and bromegrass. They can eat grocery store culls of lettuce, cabbage, endive, and celery leaves. They also like barley, wheat, and rye, especially for fall pasture. For best results, plan on 1 acre of prime pasture for each 20–40 geese. The larger the goose, the more grass it will eat. The poorer the quality of the pasture, the more space will be needed per bird. You can compensate for poor pasture by feeding supplemental grain. It will help keep your pasture in good shape if you rotate the birds from section to section, so they don't have a chance to eat any of it down so far it can't grow back quickly. In winter, your geese will try to forage and may be able to discover some dried grass and weed seeds, but they'll also need some good (not moldy!) alfalfa hay, corn fodder, grain (they like cracked wheat and rolled barley), or whatever you're feeding your chickens. Geese enjoy warm, cooked cull potatoes and can thrive on them. Feed any poultry such warm food toward evening. Then they will face the night's chill full of inner warmth. You can train them to enter shelter at night or during the winter in response to that feed.

Geese as “Weeders.” Geese love green stuff. It's their natural food. Grown geese can thrive on grass and weeds alone, if the plants are tender (they don't get good nutrients from tall, tough, stems). Feeding geese grass gives them cheap nourishment and keeps them healthy. They love to eat dandelions, morning glory, pigweed, thistles, and burr weeds, which can be a blessing. Unfortunately, however, their favorite foods in my experience seem to be lettuce, chard, young peas, beans, and corn. They'll even eat onions. If they get into the garden very often they can wipe you out, so you either have to fence your garden away from the goslings and geese, or fence the goslings and geese away from your garden. If you put them into a corn field after the corn is grown up tall and the ears are almost ready to pick, they'll get the weeds and leave the corn. But if you put them in there with the young corn plants, the geese will wipe them out. They are the same in a field of sunflowers. And beware of small trees in your orchard. Geese have been known to strip tender bark.

Before herbicides came into standard usage there was a goose-glorious period of agricultural history, when commercial growers rented young geese by the truckload in spring as weeders—12 geese considered equivalent to 1 person with a hoe. If you are buying geese to function as weeders in cotton fields, orchards, vineyards, berry patches, etc., figure 7 geese per acre. The geese should be at least 6–8 weeks old, and the weeds can't be so far ahead of them as to be high and coarse. Water and shade placement control the movement of the weeders. Geese can survive and thrive on clover, alfalfa, grasses, and weeds alone, but if their greens diet is limited in quantity or quality, some supplemental feeding in the evening is a good idea. Geese aren't so reliable in commercial fields of strawberries. If weeds are scarce, they'll eat the berry plants, and they like strawberries both green and ripe. Unlike chickens, geese don't scratch off the mulch looking for worms.

Controlling Geese

Fencing for Geese. As with 4-legged herbivores, you can turn the geese into a fenced pasture to graze. Goose-fencing keeps them in and it keeps them safe. Geese are quite vulnerable to large predators. My last summer's batch went down to the creek, and something got every one of them. Unfenced geese tend to wander away down a creek into the woods and will most likely be gone by the next day. Skunks, raccoons, or weasels will do the job, although I have heard of a case in which the geese killed a skunk. Two-inch poultry wire netting works fine for younger birds, and it need be only 18–24 inches high, since these birds don't usually fly. For birds 4–6 weeks or older, regular woven-wire fencing will work—3 feet high is good. Or even single-strand electric fencing. They'll stay in pretty well behind minimal fencing, except a heless gander may occasionally fly over and need to be caught and returned. The latest thing in goose-fencing is an electrified net, powered by an optional solar/battery system. I've talked to a grower who had such a system, and he was very enthusiastic about it. (Your hardware dealer could tell you more.) If you want to manage your goose without fencing, the best alternative is to make one of your children into a goose-herder to take care of them, as geese actually herd pretty well.

Controlling an Aviator Goose. Take the tips off the wing feathers 5 inches on one side. Just cut with scissors. It off-balances the goose. If you were to cut off both sides, he could still fly because he would be balanced. Be careful not to cut the wing, and if the bird is molting, just cut the tips of the feathers. (During molting, a thick sheath of blood vessels nurtures growing feathers. If you cut through that, your goose could bleed to death.)

Of Goose and Gander: It's easier to tell a young goose from an old one than to tell a female from a male. A young goose has soft, yellow down on its legs, an older one does not. But determining sex is difficult. Domestic geese are
all to some extent polygamous, so it's efficient to eat the surplus males. But adults all look alike except in size—except for the color-differentiated Pilgrims. There usually isn't much difference in size either, yet with sharp attention perhaps you can discern the ganders, which not only are larger, but also have a broader head, longer neck, and more upright carriage. And ganders are more aggressive. If a strange dog comes along, the ganders will be the ones to take it on. A gander also has a somewhat louder and shriller voice than a goose. If any mounting is going on, that tells you. The one on top is male. Otherwise, if you're determined to know, you have to do a rabbit-style close anatomical observation.

**Sexing Adult Geese.** Get somebody to help you. Pick the goose up, turn it upside down and start hunting around. There isn't much to see, but with practice you can learn the difference. Lubricate a finger. Stick it in the cloaca about half an inch and rotate gently several times. Now press around the outside of the vent gently to squeeze out the sex organ. It's difficult to get the penis visible, so if you get a round hole with a twisted nubbin sticking out, you know you have a male, but if you don't see a nubbin you may or may not have a female. If you can get a friend who has done it before to help you the first time, it's easier. See Sexing, published by See Sexing (Stromberg Publishing: 800-720-1134; strombergschickens.com) for more details.

The easiest way to differentiate the sexes is to wait until spring. You may not know, but the goose sure do. The one who ends up laying eggs and sitting on the nest is the female.

**Breeder Ages.** Geese do not mate well if the goose is older than the gander. A goose produces eggs for many years, the most between ages 2 and 5. However, if she eats too much and gets obese, she won't lay as many eggs, and those she does lay aren't as fertile as they would be after a diet. The gander ain't what he uest be after about 10 breeding seasons but is still good for some offspring. Geese will breed even up to 40 years of age. (101 is claimed to be the record.) If your goose don't breed their first year, don't panic: Geese sometimes don't start until their second year. Frequently, that first family may not be as numerous or hardy as later hatches. But after their trial run, most geese, left on their own, will brood and raise about 15 goslings a year.

**Gander-Maturing Ages.** The age of maturation varies. In some breeds, ganders are not mature enough to mate effectively until they are 2 years old—3 if they are of the Egyptian or Canada breeds. Slower breeds may be pushed effectively until they are 2 years old—3 if they are of the Egyptian or Canada breeds. Keep a little distance between nests to discourage squabbles. When the goose starts laying, remove all but 2 eggs until you have accumulated a nest full. The eggs can be stored in a cool place up to 2 weeks. (Wild goose eggs should not be gathered.) When you feel the weather has improved enough for her to raise a family, leave the eggs. When she has filled up her nest with a dozen or so eggs, she'll begin to set. A broody goose, in proper season, can raise up to 20 goslings. Wherever she nests she'll lay her eggs there and brood them, and then both parents will help raise the family. Once the young are hatched the mother will provide the needed warmth for them, but it will be helpful if you provide food and water in appropriately sized containers for the young ones.

**Possible Breeding Ratios.** These vary with the breed. The Canada and Egyptian geese mate only in pairs. Ganders of other breeds may pair exclusively with one female, but polygamous groupings are common. Embden, Toulouse, and African geese can suitably be grouped 1 gander to 2 or 3 geese. The Pilgrim, Buff, and Sebastopol ganders can each handle a harem of 3 or 4 geese. The smaller White Chinese gander can manage a harem of as many as 6 geese. For breeds that are capable of polygamy there should be at least 2 or 3 geese per gander for best tranquillity in the gaggle. However, there have been cases in which, as individual ganders grew older, they became monogamous and grew indifferent to all but one mate. But Chinese ganders not only accept a larger harem than any other variety, they also will not revert to monogamy.

**Goose Conservatism.** Geese generally choose partners in the fall. Once the groupings are established, it is difficult to add more geese. Geese do not mate on first encounter like so many other animals. If your proposed partners are new to each other, you'll have to allow them time to get acquainted. Many ganders do not change partners easily. Previous companions have to be completely absent for as long as a month before such a gander will accept one or more new ones. How did "goose" ever become synonymous with "stupid"?

**Laying and Nesting**

**Breeder Foods.** Geese lay best when they're getting grass, even in winter. If you are serving feed-store food, begin feeding them 15–25 percent breeder feed or mash and some good-quality hay in January, a month before egg production. A calcium supplement will assure eggshell hardness. It would also help to feed breeder geese a chicken-lying mash, if you're giving commercial feed. Whatever's in that, it does indeed push females to lay.

**Egg Laying.** Don't let overage birds go broody in January, because none of the eggs will hatch. The way you prevent that is by taking the eggs every day, leaving just one (not the same one). Unlike the duck (which dependably lays early each morning), the goose will lay her egg any old time of day. Goose eggs are used the same way you would use a chicken egg. They taste just the same to me, but are much bigger. One goose egg will make an omelet; fry one and it fills the pan. Goose eggs are also prized in decorative eggshell arts. Becky Coleman of Charlo, MT, wrote: "My pair of Embden geese were 'mature' when 1 year old. They hatched 8 goslings out of 9 eggs. That pair was hatched one spring and started breeding the following spring. I took away the first couple dozen eggs and then let the goose set with results as stated. The one egg that didn't hatch was cracked."

**Goose Nest.** Free-ranging geese will lay their eggs on the damp ground. If you have predators in the area, it is best to restrict your laying geese, but they will still prefer to nest outside. A good nest for a goose is an old tire with straw or hay in the center of it or, better yet, an old doghouse or something similar with clean straw inside of it. Smaller breeds prefer a smaller "house"—a box or barrel. Keep a little distance between nests to discourage squabbles. When the goose starts laying, remove all but 2 eggs until you have accumulated a nest full. The eggs can be stored in a cool place up to 2 weeks. (Wild goose eggs should not be gathered.) When you feel the weather has improved enough for her to raise a family, leave the eggs. When she has filled up her nest with a dozen or so eggs, she'll begin to set. A broody goose, in proper season, can raise up to 20 goslings.

Wherever she nests she'll lay her eggs there and brood them, and then both parents will help raise the family. Once the young are hatched the mother will provide the needed warmth for them, but it will be helpful if you provide food and water in appropriately sized containers for the young ones.

**Chicken-Brooded Goose Eggs.** If you have a breed that will lay more eggs and you wish to hatch them all, you can put fertile goose eggs of a non-broody layer under a setting hen and let her raise them. Take the excess goose eggs away before you let the goose accumulate her nest. Choose foster hens that are completely free of lice and ticks. A hen can cover 6 goose eggs, but they're too big for her to turn. You'll
you have enough accumulated to get the bird entirely under the bottom of a metal garbage can and repeat as needed until his wings are pinned under your other arm—you can carry him away—holding his neck in one hand and his body with your other,宇

bird's rear end on your front side. Otherwise the bird can get away somehow. Follow directions under “About Feathers.”

The feathers loose. The bigger a bird is, the longer you have to soak it to loosen the feathers. Follow directions under “Scalding and Picking a Goose.”

Incubating Goose Eggs. Like duck eggs, goose eggs need a high humidity to incubate. While the eggs are waiting to go in the incubator, use all directions listed in “Eggs-in-Waiting” under “Chickens” with the addition of a light spraying of lukewarm water every time you turn the eggs and a once-a-day dunking. (See “Incubating Waterfowl Eggs.”) Large-breed goose hatch in 30 days, Chinas in about 28, Canadian and Egyptians in 35.

BUTCHERING: If you have an old goose, I'd let it die with its dignity intact rather than trying to eat it. I wouldn't eat one over 3 years old. They get tough as shoe leather.

Catching a Goose. A good time is very early in the morning. When he comes hissing at you, bend toward him, reach out, and grab his neck behind the head. Then you can hold his head away from you with that hand, so he can't bite, and with the other arm, just scoop up his body, pinning the wings by tucking him under your arm and pressing him to your side. Hold him backward—with the head under your arm and coming out behind you and the bird's rear end on your front side. Otherwise the bird can stretch out that long neck and bite you in the face. That way—holding his neck in one hand and his body with wings pinned under your other arm—you can carry him safely where you need to go. The usual goose-slaughtering time is in the fall, when they are 5–6 months old, although you can kill heavily fed birds at 12 weeks if you don't mind dealing with more pinfeathers. At 5–6 months, they'll weigh 10–15 lb. and pinfeathers won't be a problem. Over age 10 months, their meat becomes tough.

Killing a Goose. You can hang it by the feet, stun it, cut the throat, and bleed it out thoroughly. Or . . . some friends have been continuing my education about geese. They say they shoot a goose in the head with a .22, and then skin it out rather than pick it. Well, meat's meat.

Scalding and Picking a Goose. Heat the water to 155°F—you'll need a big pot of it for a 20-lb. goose. You can heat water in a big canner to boiling and then pour it into the bottom of a metal garbage can and repeat as needed until you have enough accumulated to get the bird entirely under water somehow. Follow directions under “About Feathers.” Soak the goose as long as 4 minutes (in 140°F water with lots of agitation), depending on its size—long enough to get the feathers loose. The bigger a bird is, the longer you have to soak it to loosen the feathers. Follow directions under “Butchering a Duck” to cut up the bird. You can save the blood as well as the entrails for other stock.

Some of My Favorite Goose Recipes

BRAISED GOSLING This is a delicious way to prepare a bird that has just reached roasting size. Use a roaster with a rack at the bottom of it. Put a chunked carrot, an onion, a turnip, a pared and cored apple, and a stalk of celery on the grating. Lay the bird on that. Rub salt, pepper, and a little sage on it. Pour some boiling water in the side. Cover and roast at 350°F, 15 minutes to the pound. Baste with butter.

To make the gravy, remove the gosling when done, and mash the vegetables by pouring them and the cooking liquid through a sieve into a bowl. Skim away as much of the grease as possible after it has set a moment. Chop the cooked giblets (except the liver, which you discard), and add them to the broth. Put about 3 T of the goose grease into a frying pan. Thicken with flour, then add the broth gradually, stirring the lumps out before adding more liquid, until it has all been added. Season your gravy to taste. Serve the bird on a platter, the gravy in a bowl. Have mashed potatoes ready to pour the gravy over. Applesauce, and green peas or lima beans will complete a wonderful meal.

SEASONED GIBLET GRAY This is a variation of the above. You roast your goose without the vegetables in the roaster. Precook the neck, gizzard, and heart (again discard the liver, or do something different with it—like make paté de foie gras, for which I don't know the recipe, only that it's made out of goose livers) by boiling them until the gizzard is fork-tender. Allow enough time, because it often takes as long to cook that gizzard tender as it does to roast the entire rest of the bird. (If you wanted to use the giblets as part of your bird's stuffing, instead of in the gravy, you'd cook them the night before.) Season the giblet water with 1 t salt, 2 peppercorns, 1 clove, a bit of bay leaf, a sectioned carrot, a sectioned celery stalk, and an onion.

After the giblets are cooked, cool them. Remove the neck bones, and cut the meat into very small pieces. By now your roast goose should be done. Make a gravy as in the recipe above, using grease from your goose roast, flour, and the broth the giblets were cooked in along with the mashed vegetables from it and the minced giblet meat. Make lots of the gravy. For your second (and third?) meal from this food reheat your leftover gravy, adding sufficient water to get it the right consistency again since it thickens some while stored. Add sliced leftover goose meat to the gravy and serve over slices of bread or with potatoes.

GOOSE STUFFED WITH SAUERKRAUT This is a good fall dish, when the geese and the sauerkraut are both at their prime. Fill the goose with homemade sauerkraut, Sew up, tie into shape, and place in a large kettle. Cover with about 2 qt more of sauerkraut and add boiling water. Simmer gently for 3 hours. At the end of this time, take your goose out of the pan and put it in your roaster. Rub the skin with butter. Bake in a 400°F oven about 1 hour, or until nicely browned. Serve the boiled kraut seasoned to taste with salt, pepper, or butter, since the boiling weakens the flavor.

Life is a river. Lived right, it's a quick, clear river rushing over and around the rocks in a long straight path down to the sea. But I sometimes see someone allowing his or her beautiful river to turn into a sluggish, muddy swamp with a multitude of mosquitoes growing on top. Getting out of the swamp requires change. There's a basic rigidity of life: that it's hard (or impossible) to change him, or her, or it, or that. The place where you've got room to maneuver, to manage a healing of the swamp, is to change you. That's something always within your power to do.

But first you have to get the vivid and important realization that you are in a swamp—and you want to get out! Ain't that something. For unnumb pages I give instructions, then I preach. It's a good thing I have teenagers to
keep me humble. In this new edition I've tried to reduce the burbling and stay with the subject better than I used to. But then wonderful readers write me and say they loved thus and such in my book—and it's frequently a burble rather than a how-to they're talking about, though it's also surprising how many people have written to thank me for prosaic things such as chicken-butchering directions. So I don't really know which is most important. Guess I'll just keep doing like I'm doing.

GUINEAS

What is not considered a game bird but acts a lot like one, comes from Africa, and roosts in a tree if you don't keep it penned up? It's a guinea, called the African chicken, although it is more closely related to the pheasant. They're noisy, quarrelsome with other poultry, and probably not practical to own unless you're going to keep them penned up (because unconfined guineas hide their eggs, lose their babies, and are difficult to catch) or unless you have a major insect problem and lots of room for them to roam. But they are hardy, do have a tasty meat, and lay rich eggs.

You can get more information on guineas in the handbook Guinea Fowl, available from Inman Hatcheries (see "Poultry Supplies" under "Chickens" in this chapter).

Guinea Attributes

SELF-RELIANCE: Guineas have been companions to human beings since the ancient Greeks, yet they can never be called more than "semi-domesticated." Guinea fowl will be less dependent on you for care than perhaps any other type of animal you raise. They are able to search out their own food—except in winter—and as a result they are one of the less expensive birds to raise. They are both hot-weather and cold-weather hardy, being adapted from northern Canada to the torrid south, but will need some protection during extremely cold weather. They are less prone to disease than any other poultry, clean in habits, and are not associated with the familiar "poultry" smell.

INSECT-EATING: If allowed to roam, guineas will consume more insects than other fowl. Unlike the grain-loving fowl and unlike the plant-eating fowl, guineas are insect eaters. And they will work hard to get bugs. Guineas eat ants and will wipe out ant hills. They eat potato bugs and Japanese beetles. They do not scratch and will not harm garden or flowers; they go there looking only for insects. They chase flies, and catch them. They will ride on larger animals, picking insects and catching flies. The guinea is naturally an open-range feeder, but no matter how far it travels in daytime bug searches, it always returns home by evening.

GUINEA PATROL: Like geese and watchdogs, guineas make a loud frightened shriek when they notice strangers coming around—human or animal. They have been known to chase away wild birds like robins and waxwings from berry bushes and fruit orchards with their noise, flying into the trees and darting at the other birds. The guineas themselves are not fruit eaters and will not pick at fruit even if it falls on the ground. Guineas are on guard at night, too, and their noise can be a real problem to you and your neighbors. One of the flock, by turns, stays alert all night, ready to give the alarm. But owners have complained that they simply make noise all the time, rather than making useful noise, and they may be eaten by the very creatures they're supposed to give the alarm about. This new generation of guineas, hatched in incubators and raised in a brooder, doesn't live up to the reputation of its more naturally brought-up ancestors. When you eliminate old-time mothering and the survival lore that is thus passed from parent to offspring, you forsake education, and raise a helplessly ignorant species.

GUINEAS FOR MEAT AND MARKET: Guineas produce excellent meat. The guinea usually weighs 2–3 lb. at 16 weeks. Birds for market are butchered at 2½–3½ lb. The weight is mostly meat because of their small, flying-bird bones, a little smaller than a roasting chicken. The best time to butcher is at 4–6 months of age. The meat is all dark and as a result they are one of the less expensive birds to raise. They are both hot-weather and cold-weather hardy, being adapted from northern Canada to the torrid south, but will need some protection during extremely cold weather. They are less prone to disease than any other poultry, clean in habits, and are not associated with the familiar "poultry" smell. You can get more information on guineas in the handbook Guinea Fowl, available from Inman Hatcheries (see "Poultry Supplies" under "Chickens" in this chapter).

Guinea Attributes

SELF-RELIANCE: Guineas have been companions to human beings since the ancient Greeks, yet they can never be called more than "semi-domesticated." Guinea fowl will be less dependent on you for care than perhaps any other type of animal you raise. They are able to search out their own food—except in winter—and as a result they are one of the less expensive birds to raise. They are both hot-weather and cold-weather hardy, being adapted from northern Canada to the torrid south, but will need some protection during extremely cold weather. They are less prone to disease than any other poultry, clean in habits, and are not associated with the familiar "poultry" smell.

You can also substitute guinea in any recipe for chicken, keeping in mind that the bird is the size of a
light-breed chicken and is typically leaner than chicken and thus benefits from ingredients that add fat or moistness.

**Low-Cholesterol Eggs:** Guinea eggs are brown-shelled and are the lowest in cholesterol of all poultry—or so I've heard. They have a flavor all their own. The exceptionally light yolks are excellent for soufflés, mayonnaise-making, and baking. Their eggs are small, banty size. If you're making angel food cake, 16 guinea whites equal 11 hen whites. Guinea eggs keep well because of an unusually heavy shell. However, since they're such poor layers and hide what they do lay, you're lucky if you get very many of those wonderful eggs.

**Getting Started**

There are several varieties of guineas, but the main difference between them is color of feathers. Basically, a guinea is always a guinea. The 2 most commonly available varieties in the United States are the Pearl and the White African. Pearl Gray guineas have lovely feathers. The Whites, with their lighter skin, are sometimes preferred by restaurants, where they may be served in pheasant dishes. They're said to be not quite as loud as the Pearls, and you can see them better to follow to a hidden cache of eggs. Thomas G. Horan, RR 4, Box 417, Tamaqua, PA 18252, 570-467-3683 (evenings best), is a guinea specialist. He offers nine varieties: pearl, white, lavender, dun dotte, coral blue, royal purple, buff, opaline, or porcelain. Ralph Winter, 21357 White Pine Lane, New Vienna, IA 52065-9728, 319-853-4195, www.guineafarm.com, offers 20 colors of guineas to choose from (also 10 varieties of peafowl and blackneck swans).

Start your flock with day-old chicks from eggs set under chickens, or mail-order keets, because adult birds, when moved, are likely to wander, even if they've been penned for as much as several weeks. Your keets can be adopted and raised by your hen, or in a brooder.

**Guinea Feed:** Besides insects, the free-ranging guinea will pick up seeds of grasses, weeds, and grains. A dense patch of blackberries or such undergrowth is heaven to a guinea. If you want them to stay close to home, you can let them out only in the late afternoon to range. Completely fenced-in birds kept in a rotation setup need to be shifted every 3 weeks, but fenced range won't work for unfed guineas unless it's large enough. They need enough territory for adequate insect-hunting, since that is their primary diet. When guineas are close-penned, or cannot range because of weather or snow cover, you can feed them high-protein turkey or game-bird feed, chicken or turkey layering mash, or a home-devised chicken diet. If using a home-devised diet, they need less grain than other birds, and more protein—corn, wheat, oats, milk curd, and meat scraps. They appreciate oyster shells and limestone grit.

**Guinea Shelter:** Adult guineas are certainly happy roosting in an orchard, all year round. But some owners prefer to teach them to roost in a poultry shed. This solves the problem of having to shoo them inside in extremely bad weather (guineas intensely dislike snow). They don't need a heated or insulated shelter. To teach a guinea to sleep indoors, you start when they're about 2 months old and get the urge to roost somewhere high. Each night, drive them into the place where you want them to roost. They can be taught the habit. Or you can let them roost outdoors in the summer. Then each evening of the fall feed them nearer the place you want them to roost, so that by the time really cold weather comes it won't be so difficult to get them to sleep in there. But for easiest and best management they should be confined in bird runs. (See "Pheasant Housing" under "The Game Birds."

**Guinea Pens:** At least 1 cock and 3 or 4 hens should be penned together. The pen size should be a minimum of 6 x 10 feet for this group. Sides 5 feet high on a pen that small will prevent the birds from flying out. If they are to be penned during laying season, place the pen in such a way that at least 1 corner contains brush or tree limbs, deep grass, or hay. Guineas do not like nesting boxes. The hens will lay their eggs on the ground where they feel securely hidden. Make a special egg-door in the fence by the nesting place, so you can gather eggs without coming into the pen. Another good argument for letting the birds roam, at least once a day, is to help you gather the eggs unseen. What guineas see, they remember, and they don't make a mistake more than twice.

**Worms:** The primary health problem a guinea can suffer from is worms, round and tape. It is possible, but risky, to worm them.

**Guinea Reproduction**

**Male and Female:** It's difficult to tell the sexes apart. Baby guineas cannot be vent-sexed. After the keets are 12 weeks old, a cock's comb is just a little larger than the female's. The adult cock's comb and wattles are just a little more developed than the female's, and the white on his neck extends farther down. The cock's call is one-syllabic, while the hen's is either a 1- or a 2-syllable call, variously rendered as "put-rock," "buck-wheat," or "good-luck." If one bird is separated from the others, you can tell by its call what sex it is. Males are the ones that rush about with wings lifted a little, an expression of avian courtship. Under natural circumstances guineas are monogamous. But they will accept harem life. You can maintain egg fertility with as few as 1 cock to every 4-6 females. The social grouping so formed will be permanent. The cock always remains protectively near his hens. If the hens have 1 wing clipped and are kept in a pen, an unclipped cock won't fly away and leave them. Guinea can mate with chickens. The resulting offspring, like the mules that result from horse-donkey matings, will be sterile.

**Nests:** Since guineas are known for laying in out-of-the-way places, its a good idea to confine them each day until they've laid (until 3pm if you've got a number of hens). If your guineas are free-roaming, you will have trouble finding their eggs. Guineas are seasonal egg-layers, and they hide their nests. There's an art to finding those nests. When the laying season begins (late March to mid-May, depending on your climate), watch to see where they go. The flock will go together to lay between about 11am and 1pm. A guinea nest will be a shallow hole scratched in the ground. All the hens may lay in the same nest, even at the same time. The cock stands nearby to guard them. You must see without being seen. Guineas are easily upset and may quit laying, or move the nest. So don't ever come near while they're laying. Just mark the spot visually, and then, after they've gone on
When you take out eggs, leave from 1 to 5 (opinions vary) marked ones. Never let them see you take the eggs. A guinea hen will set when she gets an accumulation of 12–24 eggs. So, you’ll get a greater total of eggs from which to hatch keets (under a hen or in an incubator) or for eating, if you mark and leave those 1–5 eggs in her nest and take the others to put under setting hens. Rotate the ones you’re leaving, and don’t worry about their freshness—remember that guinea eggs are the best keepers. With you taking more of the eggs, the guinea won’t get broody until late summer. If you want to break her from the notion to set, just take all the eggs. Guinea broodiness breaks up easily.

**INCUBATING GUINEA EGGS:** Guineas lay far fewer eggs than commercial chicken and duck breeds. A hen will lay maybe 45–55 eggs a year, in the period from May to September. The good news is that guineas live a long time, and, like geese, lay as many eggs when they’re relatively old as they did their first year, and their eggs remain as fertile.

**HATCHING GUINEAS:** You may return 12–15 eggs to a guinea hen for setting, set 20–28 guinea eggs under a brooding chicken hen, or incubate the eggs. The eggs take 28 days to hatch. Brooding guinea hens have been known to give up on the rest of their eggs once 2 or 3 keets have hatched. The remaining eggs can be saved if you move them to an incubator or chicken hen. Forced-air incubator setting should be 100°F; during the last 3 days of incubation it should be 99°F. Still-air temperature would be 101–103°F. Humidity: 83–85. Do not turn eggs after 25 days. Humidity is essential because of the hard shell. Humidity during the last 3 days should be 90–94. For eggs incubated under a hen in a dry climate, or in dry weather, it will help the keets hatch out of their thick-shelled eggs if you occasionally sprinkle them with warm water. If you’re hatching only part of the eggs, choose the larger ones, because larger eggs tend to hatch out larger birds. Because of keet susceptibility to lice, if you plan to hatch guinea eggs under a hen, she needs to be louse-free, and sitting in a clean nest. The last week before hatching, give her an antilouse treatment, and put her on fresh sod for nesting material. A little pinch of fine-cut tobacco mixed in the nest litter helps. Banty hens are better for the job than a heavy-breed hen, because they’re less likely to cause heavy-footed harm to the fragile-boned guinea keets after they hatch.

**KEETS:** The guinea chicks, or “keets,” are tiny and vulnerable. They are available from hatcheries from about April through August for about $1.50 each. For the first few weeks, you’ll want to keep them penned up and feed them frequently. Start with 6 meals a day for the first month. Then give them 4 meals a day for 2 weeks. After an additional 6 weeks of 3 meals a day, you can feed guineas much like turkeys. They’ll grow twice as well on turkey starter feed than on chicken starter, but they can make it on (non-medicated!) chick starter. If their feed is to be home-devised, it should be high in protein, with chopped hard-boiled eggs, crumbled cornbread, and cottage cheese or clabbered milk, as well as bread crumbs, oatmeal, and a few greens, with fine grit. Keets cannot eat a coarse feed. They need a 95°F brooder warmth and to be in groups no larger than 25. They can get through 1-inch holes and fly by the end of 2 weeks. They can drown in chick-size waterers. During the first 2 weeks water them from very small, shallow containers with marbles or rocks in them, devised so they cannot possibly get wet. The keets will stand on the rocks and drink the water. Lice will kill them. Make sure your brooder area is clean in this regard. Wood shavings are a good litter for keets. If you bring up the young keets with chickens of the same age, they learn to come in at night, with no work on your part.

**GUINEA MOTHERS:** Guinea hens are not the best mothers for their young, so it’s really preferable to raise them with a chicken or in a brooder. Modern guinea mothers don’t have good judgment about how far a keet has the strength to go, or under what conditions. Keets mothered by a chicken tend to be less wild and more manageable. Guinea keets that are to be mothered by a hen should be penned for the first few days with the hen, until they learn to recognize her “come-here” call. For the first 2 weeks they mustn’t roam in wet grass or get caught in the rain. Use a portable coop and move it every day to fresh range. By the time guineas are 4–6 weeks old, when they begin to develop adult feathering, hen and chicks should be completely free to wander. Keets raised in a brooder can be shifted to range and range shelters when 6–7 weeks old. Once on free range the keets need no more supplemental feeding. Guineas are herd creatures, and keets raised with a hen will stay with her until they are fully grown, which may deeply upset a banty hen who wants to go off by herself and set privately on a new clutch of eggs. But the guineas will want to stand guard, guinea-style, while she lays her eggs, and roost with her at night.

**Catching a Guinea**

My helper, Pam (a treasure: a grown woman with a husband and a beautiful baby, who volunteers her time for the cause of making this a better book; God bless her!), at first kept trying to upgrade my language. She wanted me to say “Administering a Pill to a Bird” rather than “Giving a Bird a Pill” and “Guinea Capture” rather than “Catching a Guinea.” I’ve been fighting for the right to use Plain English on the printed page for 25 years. So I had a talk with her. I asked, “Why must we have a 2- or 3-syllable word when a 1-syllable word can do the job? Why must we make the reader of a how-to book feel like the writer is so-damn-smart and been-to-college?” I explained that my big worry is how to manage to get that reader, you, to truly believe that you — whether amateur, city-raised, Ph.D. or only 6th-grade graduate—can do all this stuff, too. Doctors “administer” medicine. You and I give pills! Right?

Plain language empowers plain people. That’s the whole idea: that you, too, could do any or all of the stuff in this book. And it’s okay—it’s great!—whatever you choose to try. When you give knowledge to people, you empower them. So many times some beautiful person has come up to me and said something like, “I love your book because I can understand what you’re saying! You write like people talk!” I do that on purpose. I wish I did it better, and more. Using Plain English in a book doesn’t mean the writer is dumb. My IQ is awesome. If I wanted to write more obscurely, more formally and distantly, in the usage of the literati, I could. But I don’t want to. Talked Pam into my point of view, too! Like I said, she’s a neat lady. And well on the way to recovering from that college degree!
So, to catch (or “capture”) a free guinea ... you can make anything work once or twice: shine a spotlight in her eyes, teach her to feed in an open coop and then sneak up and shut the door, or run her into netting supported by stakes. Using a net on the end of a long handle is a good technique. Be careful when handling guineas, though—they're bones are fine and their legs easily broken. It's helpful if they've been taught to sleep indoors. And shooting them in the head always works, if your aim is good!

**The Game Birds**

Pheasants, partridge, quail, grouse, and peafowl—the “game birds”—vary a lot, but in general they all are fragile, they typically do not reproduce efficiently or at all in confinement, their eggs must be incubated, they are raised in total confinement (either in runs or cages), and they are chronically nervous. The main argument for keeping them is the extraordinary beauty of some varieties (the pheasants in particular), the small size of some (particularly the quail) that make “garage ranching” possible, and their market value as specialties. Game birds are usually fed commercial game-bird starter/grower/finishing/breeding rations. Whether you can make them pay or not depends on your knowledgeability and skill as a handler and the quality of your facilities—as well as the current state of the market and your ability to network with it. For highest egg-laying rates, many growers send older birds continually on to market, replacing them with their offspring as breeders. That way they’re assured of having young, vigorous breeders all the time.

**Game-Bird Books and Supplies:** There are lots of books on raising game birds in general and on each specific game bird, too. Inman Hatcheries (see “Poultry Supplies” under “Chickens”) offers game-bird books: *Raising Game Birds, Game Bird Propagation, Pheasant Breeding and Care*, and *Partridges—Their Breeding and Management* by G.E.S. Robbins. Other useful game-bird references are *Pheasants—Their Breeding and Management* by K. C. R. Howman (helpful to newcomers) and *Raising Game Birds*.

Join the North American Game Bird Association, run by and for game-bird breeders, for $45 ($55 Canada) per year. You get a directory of members, listing in a hunting directory of members, listing in species and age. The smaller game birds, such as quail, pheasants, guineas, partridges, doves, ducks, and swans. There's a large classified ad section in every issue: 801-575-1111; PO Box 171227, Salt Lake City, UT 84117-1227; www.gamebird.com.

**Game-Bird Housing**

**Game Birds and Stress:** Because of their natural wildness, game birds are easily stressed by life in captivity. Stress makes them more susceptible to disease. Crowding, poor nutrition, changes in their diet, changes in their housing, and handling of any sort tend to be stressful to them and must be managed as carefully as possible.

**Pens for Small Game Birds:** It's best if you separate birds by species and age. The smaller game birds, such as quail, are usually raised in tiered metal battery-style pens or in homemade off-the-ground pens that have a wood frame with poultry-netting sides and small-mesh flooring. A basic homemade pen uses 2 × 4s for the frame and 4 legs, which support a 2 × 2 × 4-foot cage. The floor of the cage is made of hardware cloth (a rugged galvanized screening). The wire floor allows droppings to fall through to below the pen where they can be gathered up for the compost pit. The sides are of chicken wire. The top can be made of chicken wire if the pen is inside, wood or metal if it is outside. Such pens can be on tall legs with a back-sloped roof and can be fixed on posts or portable.
**Housing for Larger Game Birds:** Pheasants, for example, are usually kept in sizable cages that have a chicken-wire top and sides. Such a cage could be partitioned off inside an existing building—about 6 × 12 feet—or built outside. Outside ground pens can be built to include brush, one or more trees, and shrubs; that provides a more comfortable and natural environment for the birds. Dimensions can be adjusted according to the variety of bird, number of birds, and the space you have. Height should be 6 feet. Outside ground pens need a south-facing shelter to protect the birds from sun and storm. If your climate is cold, the shelter needs to be a little house with a bird-size door to get into it. The ground in a pen needs to be kept clean, either by spreading a heavy litter, such as that of tree leaves, which are regularly stirred and occasionally changed, or by regularly raking and removing bird droppings. Game birds, like chickens, can become afflicted with external parasites such as mites and lice.

**Game-Bird Breeding:** Separate your breeders in the correct ratios of males to females for your particular species about 4–5 weeks before you will begin gathering eggs. Both males and females will be stimulated to produce if you supply 17 hours of light a day and maintain a temperature of at least 60°F. Here is information on the specific game-bird varieties: first pheasants, then partridge, then quail.

**Pheasants**

Pheasants are large, colorful relatives of the other game birds—partridge, quail, and grouse. The males are the most colorful as well as the largest. Pheasants are not good egg producers, but they are, in many cases, beautifully feathered birds. They aren't the most practical for home food production, but they might make money for you.

**Pheasants for Hunting:** Some pheasants are raised for hunting. Raising sports-variety pheasants is under the control of your state game commission. In the states I know of, you must have a permit to raise them in captivity. In Idaho there are unannounced visits by an inspector making sure that certain requirements with regard to their housing and so on are met. So talk to your state game commission and find out the rules before you order a game variety. They don't regulate the "show" pheasants—the goldens and silvers, for example.

![Ringneck Pheasant](image)

**Pheasant Housing:** Pheasants are the most timid domesticated bird there is. Free-running Chinese Pheasants will mate with chickens, resulting in an impractical hybrid. Pheasants will absolutely suffer in crowded quarters with lots of commotion. They need to be in a big, long pen where they can get away from you. It has to have a roofed top to prevent them from flying away. If they get out after belonging to you awhile, they may hang around, roosting on a board fence or some such until hunting season. Then they will disappear. They can generally take care of themselves in the wild okay, but to harvest them you may need luck and a .22.

**Debeaking:** Not necessary, says Tracy Haan of Sioux Falls, SD. Use a special pheasant lamp, plus mix baby chicks with the baby pheasants: "It works wonderfully." Separate the species when grown. "Adult pheasants won't pick each other if they have ample flying and roosting space (especially roosting space)."

**Pheasant Reproduction:** Pheasants are polygamous. For maximum economy, pen 1 cock with 4 or 5 hens. Don't put more than 1 cock in the same pen. Game hens have a tendency to leave the nest after their first few chicks hatch. You can take the abandoned eggs into the house and incubate them to finish up the hatch. Then add the remaining chicks to their mother's family. Or you can collect the eggs and do all the hatching in an incubator.

**Incubating Pheasant Eggs.** Pheasant eggs will hatch in 23–26 days, varying with the exact variety of bird. Forced-air temperature is 100°F, but the temperature in the last 3 days of incubation should drop to 99°F. Still-air temperature for incubation would be 101.5–102.5°F. Desirable humidity is 86–88. Do not turn eggs after 21 days. Humidity during the last 3 days should be 92–95.

**Raising Pheasant Chicks.** Chicks are available, May to August, from hatcheries. You can’t tell ringneck pheasant chicks apart by sex until 6–8 weeks, when they finally develop distinguishing plumage. For a method of sexing day-old ringneck pheasant chicks, see Sexing (Stromberg Publishing; info@strombergschicken.com). Use turkey starter or game-bird starter to feed them. (Or you can feed them a home-devised diet as you would for chickens—heavy on the protein side.) Young pheasants are easily stressed and need calm and routine. They are also highly cannibalistic and often use their very sharp beaks on each other, requiring an ongoing struggle with debeaking and anti-pick lotion on your part. Interesting food that needs a lot of picking at, like crisp fruit and vegetables and grain, also helps divert the birds from picking at each other. Pheasants mature in 26–28 weeks and will dress out at 2½–3½ lb. They start their own laying career at 7 or 8 months of age, or the next spring. Commercial growers bring them into production earlier using artificial lighting to create a long day.

**Partridge**

Before ordering partridge, check with the state game-bird regulatory agency in your area that controls wildlife management. You may need a permit. Chukar partridge come from India, weigh about 1½ lb., and are raised for meat. They have a beak that grows so fast, it must be trimmed (debeaked) frequently or it will become difficult for them to pick up feed. Males and females look the same, but the males are a little larger. Adult chukars are sexed on the basis of the leg nubs. The male has short nubs on both legs. Hens may have the nubs, but never as large as the male ones.
Ventr sexing is the surest way to tell. Chukars are not monogamous. They reach breeding age at 26–28 weeks, but hens will wait to begin laying until the next spring after hatch unless forced with artificial light (17-hour days).

**SHELTER AND FOOD:** A 2 x 2 x 4-foot pen could house 15 chukar. One 8 feet long could hold 30–35 chukar. Breeders are usually housed in a colony pen (2 x 2 x 1 foot) with 1 male to every 3 or 4 females. It’s better to house these polygamous birds in separate families to avoid cock fights. Young chukars are easily stressed by rough handling, changing pens, changing their food, or changing their feeding routine. They do best if kept in the same pen from hatching to maturity, after which their nerves get calmer. Chukar do well on a game-bird ration, starter until 3 months old, then grower mash until butchering. For your breeders there’s a game-bird breeder mash. After 6 weeks of age, supplement with grain and crisp fruits and vegetables to reduce cannibalism.

**INCUBATING CHUKAR EGGS:** The incubation period will be 23 or 24 days. Forced-air temperature for incubation is 100°F, dropping the last 3 days of incubation to 99°F. Still-air incubating temperature should be 101–102°F. Humidity is best at 80–82. Do not turn eggs after 21 days. Humidity during the last 3 days should be 90–94. For information on vent-sexing chukar chicks (and other fowl) see Sexing (Stromberg Publishing; 800-720-1134; strombergschicken.com).

**Quail**

These, and pigeons, are the smallest of the domesticated birds. Quail require the least space of any food-producing domesticated animal and can be raised in a apartment. A 2 x 2 x 8-foot pen could hold 50 quail. Coturnix and Bobwhites are the most commonly raised quails. Bobwhite quail are raised to eat as dressed birds and for shooting preserves. Coturnix are raised for their eggs (says my friend Lee, “Quail eggs are a son of a gun to peel”), as well as for meat. Blue Scale and Gambel quails are some rarer varieties. Bobwhites are the most difficult quail to sex. The vent system has to be used. Quail eggs are small. An incubator that will hold 90 pheasant or chukar eggs can hold 200 quail eggs. If the incubator can hold 300 of the larger eggs, it will hold 800 quail eggs. For more information consult Albert F. Marsh’s Quail Manual (Garden Grove, CA: Marsh Farms, 1976) or A Quail in the Family by William J. Plummer (Henry Regnery Co., 1974).

**COTURNIX QUAIL:** After centuries of foreign cultivation, Coturnix quail were imported to the U.S. There are various breeds of Coturnix quail: Pharaoh, Tuxedo, Manchurian, Golden, British Range, English White, Australian Fawn, and Giant Brown. The Giant Brown was developed at Texas A & M Univ. by Dr. Fred Thornberry, Poultry Science Dept. It’s a wide-breasted variety that reaches a tasty 10 oz. at 6 weeks. They’re available from Bear Bayou Quail Farm, PO Box 514, Channel View, TX 77530; 281-452-5407; bearbayouquail@flash.net.

**SEXING COTURNIX:** In 2 varieties, the Pharaoh and the Manchurian Golden, the sexes can be color-distinguished once the chicks are 2 weeks old, at which time they grow new feathers with their distinguishing colors. Males have a reddish breast tint; females have a gray-mottled and more speckled breast. The other breeds are the British Range black quail, the English White, and the Tuxedo breeds, and they can be sexed only after 6 weeks, when they are sexually mature and the hens have started laying. A laying hen will have an enlarged vent of a more bluish color. The sexually active male has a ball-like appendage immediately above its vent. If the ball is squeezed, foam will run out. If the male does not have the ball, he will not breed. Coturnix females grow to be about 20 percent larger than the males. Females may be heavier yet because of the developing eggs in their bodies, so comparative weight can be another way to sex them. They also have different calls. The hen says, “whee-whee-whe.” The cock says “grr-ttt-ttt-ttt.”

Coturnix are rather sensitive to handle. Some people do very well with them; other people have a hard time getting very many eggs—and the egg is the basic purpose of raising them. They are a small bird with a very small egg, but those eggs are almost identical in flavor and nutrient content to chicken's eggs. And the Coturnix needs far less feed to produce the same weight of eggs. They start laying eggs when they are a little over 7 weeks old. They can be very productive egg-layers with high fertility, hardy, and fine to eat, though the dressed weight of a mature Coturnix is only about 4 oz. The hen quail averages 6 oz., the cock, just a shade less. Males can be eaten at 6–8 weeks. Coturnix quail are characteristic of their game-bird relatives, elusive and alert. If they escape—and it’s possible—they will be gone forever. Low cages prevent injury from the quail’s tendency to fly straight up. These quail require plenty of water because the egg the hen lays almost every day is ½ her body weight, and a good part water. Adult quail can eat turkey laying mash, or home-devised diet for confined guineas. You can experiment with other foods to see what they enjoy.

**COTURNIX REPRODUCTION:** To select breeders from a batch of chicks, choose at 6 weeks of age healthy, active birds that have the proper breed characteristics. The ideal sex ratio is considered to be 1 cock per 2 hens, though they can be raised as monogamous pairs or in a ratio of 1 cock to 3 hens. Don’t keep a solitary bird; they need a mate or the single may die. The young are mature and in full egg production by 35–50 days and will be fully grown at 10 weeks. The hens will lay 5 or 6 eggs per week, so 20 to 30 hens can lay about 1,250 eggs—which may be hatched or eaten—in 10 weeks. So their potential reproduction rate is phenomenal. Laying birds are fragile (egg inside!) and should not be handled unless absolutely necessary, and then very carefully. The Coturnix quail lays a large...
INCUBATING COTURNIX EGGS: The eggs should be incubated 16–18 days, 99.5°F (forced-air) or 101–101.5°F (still-air), at 85 percent humidity, turned a minimum of 4 or 5 times per day. Temperature the last 3 days of incubation can drop to 99°F. Do not turn the eggs after 15 days. Humidity during the last 3 days is best at 90–94%. Regular incubator trays won’t be suitable for the small quail eggs but can be adapted by using an upside-down egg tray in there to hold them. Using an incubator, your quail production, because of their rapid maturation and prolific egg-laying, can be extraordinary. For quail to set their own eggs, supply extra space and nesting material of soft grass. Each hen will produce at least 4 families per year, each of 10–14 young quail.

BOBWHITE QUAIL: These birds are monogamous and usually pair for life. The male has a white eye-stripe and brown throat. Females have a buff line through the eye and a buff throat. They are physically mature at 16–20 weeks and, if mated, will start laying eggs at 24 weeks. The mature birds weigh ½ lb. If dressed out for eating, a Bobwhite will weigh a little less—about 6 oz. Bobwhite normally mate mid-May to mid-August and lay from 50 to 60 eggs (varying with climate and weather conditions). However, if provided 17 hours of light per day and kept in a temperature over 60°F, the bobwhite hens, once they reach the breeding age of 6 months, will lay eggs the year round—200 or more per year. Bobwhite quail will not set their own eggs in captivity. To incubate these quail eggs allow 23–24 days. Forced-air temperature should be 100°F, dropping the last 3 days to 99°F. Still-air temperature should be 101–102°F. Humidity should be 84–86. Do not turn the eggs after 21 days. Humidity during the last 3 days should be 90–94°F (wet bulb). In the brooder the Bobwhite chicks should start at 100°F, gradually reducing to 70°F when they are nearly grown.

QUAIL CHICKS: These are so tiny that if you use a regular poultry waterer, you must put rocks or marbles in the waterer to keep them from drinking. There is specially designed chick and adult equipment marketed for quail raisers. G.Q.F Mfg. Co., PO. 1552, Savannah, GA 31498, and Rocky Top General Store (see “Poultry Supplies” under “Chickens”) are among those. Raise Coturnix quail chicks by “Chickens” directions with “Guineas” refinements. Or they can be fed game-bird starter to 6 weeks, grower to adulthood, and breeder ration for breeders. The chicks will die of dehydration before they’ll drink dirty, stale water.

QUAIL HOUSING: A 2 x 2 x 8-foot pen could comfortably house 20–25 quail. If such a pen is divided into eight 1-foot-wide compartments, you could keep them in individual colonies; a pair of Bobwhite; a trio of Coturnix. When birds are housed in smaller groups it’s easier to identify less productive and/or disruptive ones. A water trough in the back and a feed trough in the front is considered ideal. A wire floor allows droppings to fall through. If the floor is slightly tilted to one side, it allows the eggs to roll gently out of the pen to an outside gathering place—which keeps them clean and makes them easy to get.

USING QUAIL MEAT AND EGGS: The young birds are fine eating, either roasted whole (for ½ hour), halved and broiled, or substituted in any squab (young pigeon) recipe. The eggs are a delicacy in the pickled form. Butcher at 6–14 weeks of age. (See “Pigeons and Doves” for directions on the slaughter of small birds.) Coturnix eggs are said to be “rich, mellow and usually served fried, poached, boiled, or pickled, are delightful decorations in salad dishes, and make interesting appetizers and hors d’oeuvres.” That information was from Fred Frey, Missoula, MT. He also wrote, “Their meat is all dark, no white meat on the breast. Recipes include browning in a heavy fry pan followed by 45 minutes of baking. Some include sauces or baking along with a dressing. Very good if not allowed to dry out, which a small bird like this can easily do.”

Peafowl
If you join the United Peafowl Association (US $25, Canada $30, others $35 per year), you’ll get the bimonthly Peafowl Today; Dennis Erdman, Treasurer; 570-425-3364; PO Box 24, Klingerstown, PA 17941; derdman@ruralife.net; www.peafowl.org. Bill and Monte Haney offer 30+ varieties of peafowl: Box 612, Angelton, TX 77516; 409-848-0407 or 409-849-7464; 409-239-1931. Visitors by appointment only. Roughwood Aviaries offers 17 kinds of peafowl and is “Home of the Purple Peafowl”: PO Box 71, Austin, IN 47102; 812-752-2799; In@scottsburg.com. Bayou Bird Farm has seven varieties: 846 Elsie Dr., Princeton, LA 71067; 318-949-2294. There’s more info in Keeping Peafowl by James Blake. D. C. Townsend offers more info on raising peafowl at www.voy.com/28388/1151.html.

Pigeons and Doves
Both pigeons and doves are technically members of the pigeon tribe, but doves are smaller. There are many varieties of pigeons that vary considerably in size, color, and weight. Most pigeons are raised for meat because they grow so fast. In fact, during the 1930s depression, pigeons were the primary source of meat for many families. All of the pigeon and dove varieties are monogamous, raise young called squabs, and feed them “pigeon milk.” Pigeon milk is an interesting substance that is secreted by the lining of the parents’ (both sexes!) crop. The milk is rich in protein and fat and the parents pump it out of their mouths into those of the squabs. Caged pigeons must be confined as permanent pairs, but only a few pairs can produce enough squabs to vary your menu. You can keep them in wire cages or in ground runs.

BREEDS: Pigeons have been domesticated for thousands of years. They came squab recipes dating back to the Romans. There are many types and colors of pigeons to choose from. When you purchase your starting pair, be careful to distinguish between the squabbing breeds and the exhibition breeds—they are very different. The exhibition types don’t raise as many squabs, their squabs are not as large, and they have a longer molting season and fewer squabs in the winter. The Runt (a breed unchanged since Roman times), White King, Giant Homer, and Mondaines are the premier squabbing breeds. They are big and healthy, and are used only on casual attention. To buy birds, consider Dynamite Lofts, which offers rollers and spinners: 631-395-3249; PO Box 167, Shirley, NY 11967. Herb Schull offers 19 breeds of pigeons: W8744 Park St., Pembine, WI 54156. James M. Feasel offers several breeds: 419-639-2935; 2373 County Rd. 181, Clyde, OH 43410; jfeasel@glis.cc.
Pigeons in Print: Making Pigeons Pay: A Manual of Practical Information on the Management, Selection, Breeding, Feeding and Marketing of Pigeons by Wendell Mitchell Levi (1946) is a classic on the subject. Also try Pigeons by B. Hunt and B. Waldman (Prentice Hall, 1973); Doves and Doves by Peter and Jean Hansell (Millstream Books, 1988); Raising Turkeys, Ducks, Geese, Pigeons and Guinea by Cynthia Haynes

Pigeons Gone Wild: Pigeons bought to be pets or food animals will go wild, if they are neglected—or encouraged to be independent. If a pair move out of your cage, you'll have pigeons in your chicken house, pigeons in your barn loft, pigeons in your garage, pigeons in your machine shed. You can pat yourself on the back because the pigeons are foraging and making it quite well on food they steal from your other animals and neighbors. But if they are roosting over your car, you will have a fresh set of droppings on the hood every morning. They will turn every building they sleep and nest in into a chicken house full of smells—"guano." They reproduce really effectively: in a few years your homestead may have more pigeons than are welcome. Cities are famous for their downtown pigeons, which is exactly the same situation, only a public problem rather than a private one.

Dealing with the Independents. If you get pigeons where you don't want them, you'll have to wrestle with the situation until they are all dead or back where they are supposed to be living. The adults can be caught, with effort, in traps. But it's not an easy matter to harvest squabs from the kind of places pigeons choose for their nests. (Best done in the spring.) Independent pigeons will raise only about 5 squabs per year. (Independent pigeons will raise only about 5 squabs per year.) The other has to do with time: free pigeons will find much of their own food. Confined pigeons are not efficient feed-to-meat converters. A breeding pair can consume 100 lb. of grain in the time it takes to produce 10-12 squabs. But if you do keep confined pigeons, feed them twice daily with a commercial pigeon ration or a high-protein diet, heavy on the grain and legumes side, together with grit and salt—and vitamin D (cod liver oil) every 2 weeks if they're getting inadequate sunshine. Temporarily confined pigeons have also done well on a combination of grains and legumes. Be sure all feed is dry and free of mold. Pigeons need plenty of clean water, both to drink and to bathe in.

Shelter. Free-ranging pigeons will appreciate a small house with at least enough room for nesting and eating your offerings. It can be like the shelter for confined pigeons, only with an outside landing perch next to a doorway for them to enter and leave. Their dwelling should be designed so that cats and other predators cannot enter. Build it so you can keep their loft dry and well ventilated. In cold weather your pigeons will need some extra warmth to keep their quarters above freezing, since they will still be incubating eggs or raising squabs. Confined pigeons need more room than you might think—they're not like Coturnix quail in this respect. A pair of pigeons will appreciate a dovecote (pigeon house) at least 4 feet square in floor area, about 2 feet high, with a chicken-wire partition to make 2 apartments. Provide a window for the front side of the dovecote, which you should place to get maximum sunlight. If you have the space, a 10 x 15 x 7-foot flying pen would be an ideal completion of the arrangement. Clean out the guano once a month. Provide a large pan of water for bathing as well as for drinking.

The Nest: Each pair needs a nest. Use an old-time wooden orange crate sitting on the floor of their room. Some pairs will maintain 2 nests, 1 with newly laid eggs and 1 with still growing squabs, which is why the dovecote needs 2 apartments. Provide straw, pine needles, or other fibers for nest-building material.

Getting a New Pair Settled In. You'll probably start by buying a pair or two of pigeons from a poultry dealer or a nearby pigeon owner. At least, you hope you have a pair.
Pigeons are difficult to sex accurately, even by experts, especially when the birds are young. Be sure they are healthy. Swellings on the necks or near their mouths are probably canker disease. Have their shelter ready before you bring them home. Let them loose in it. Keep them there for 3 weeks. It must be a place where they can see out, if you intend to let them loose eventually and want them coming back. Feed them well. At the end of the 3 weeks, if you want them to be free, open the door to their flight deck, give them a little grain or other food every day, and that's all there is to it.

**Domestic Relations.** Sexing some breeds of pigeons is very difficult. Males are a trifle larger, act more aggressive, coo more actively at other pigeons, and may at the same time “dance” (strut and turn completely around). Males will fight other males. The male pigeon chooses the nest site, chooses his mate, and nudges her to his nest. Young pigeons first take a mate at 6 months. If you see a bird mounted momentarily on the back of another, you have a pair. At night, pairs roost side by side. Pigeons mate for life, but if widowed or divorced by humans, a pigeon will accept a new mate. The time to mate a pair is during the molting season, between February and July. Place the new cock next to the hen, but divide them in the center with chicken wire. The male will court his lady, billing and cooing in classical dove style. He also proves his practical abilities by feeding her partly digested grain. If she accepts, you can take out the partition and consider them a pair.

**On the Nest.** About a week after the molt is over, the hen will lay an egg, then another in a day or so. If the female lays more than 2 eggs, remove the extras. Two healthy squabs are all that can be expected at one time from a pigeon family. Once both eggs are laid, the pigeons will incubate them—both parents sitting in shifts on the eggs. Usually the female is sitting on the eggs from about 3pm, through the night, on until about 10am the next morning. Then the male takes over until afternoon when the female is back on. That's one way to sex your pigeons. The one on the nest at noon is probably the male. The one on the nest in the evening is probably the female.

**Incubating Pigeon Eggs.** To incubate pigeon eggs, allow 17 or 18 days to hatch. Use a forced-air temperature of 99.5°F; the temperature the last 3 days of incubation can be 99°F. Use still-air temperature of 101-101.5°F and wet-bulb humidity of 85%. Do not turn the eggs after 15 days, and raise humidity during the last 3 days to 90–94.

**Pigeon Parenthood.** The eggs will hatch usually within a few hours of each other. The adults will do all the work of caring for the young, but you should make sure they have what they need. When a pair of squabs are about 3 weeks old, a good hen will begin laying more eggs. When the adult birds begin to incubate the new eggs, it is imperative that you remove their fledgling squabs to your table or deep freeze. Squabbing breeds have been developed with this expectation in mind. The squabs are very dependent on and demanding of the parents; it is too difficult for the adult pigeons to try to incubate eggs and care for squabs at the same time. But some, less prolific, pairs will wait 6 weeks to lay more eggs. If you are not rushed by the presence of new eggs, take the squabs when they're feathered out under the wings; they'll be about 4½ weeks old. You can slaughter then or feed them out to 6 weeks old and then slaughter. Your breeding pair will live to be about 7 years old, laying all the while. 

**Lice.** Infestations of lice can be dealt with by adding small amounts (not more than 1 T. per 2½ gal. water) of sodium fluoride to the pigeons' bathing water.

**How to Kill, Pick, and Clean a Pigeon**

Squab size is anywhere from 14 to 28 oz. Most breeds will attain this size in 25–35 days. Break the neck with a sharp, twisting pull. Cut off the head, hang by the feet, and let bleed. Or place the bird on a chopping block and sever its head with a very sharp knife. Now scald and pluck away the feathers (see directions in the “Chickens” section), or skin the bird. To skin a small bird, you tear open the breast skin and then pull skin together with its feathers upward and outward. Pull the skin off over wings, legs and back. To clean the bird, see instructions under “Chickens.” The poultry scissors method is easiest with small birds.

**COOKING PIGEON:** Preparing squab shouldn't be confused with preparing gone-wild pigeons captured in the field, forest, or your barn. Exercise results in dark meat and the gamy flavor of wild things—which is not necessarily distasteful. But squab, since it has never done anything but sit and swallow, has pale meat and a mild taste. It will weigh ¾–1 lb. Squabs can be fried, roasted, or broiled. Older birds can be pot roasted, made into the traditional pie, or stewed.

**BROILED SQUAB** Split the bird and flatten the resulting pieces. Rub them with butter, and sprinkle on salt and pepper. Place them on the broiler, breast side to heat. Serve each half-bird on a thick slice of buttered, toasted homemade bread with a sauce poured over—either gravy or heated condensé mushroom soup.

**PIGEONS ROASTED IN GRAPE LEAVES** Brush the birds inside and out with melted butter and dust lightly with salt and pepper. Wrap each bird tightly and thoroughly in grape leaves—2 should do the job. Place the wrapped birds side by side in a baking dish, about 1 bird for each person you are feeding. Bake at 350°F until they are cooked through and tender. To serve, remove and discard the grape leaves. Make a sauce with the pan drippings, 2 T. butter, and the juice of a lemon, mix well, and then pour it over the birds on their serving platter.

**TRADITIONAL PIGEON POT PIE** Stuff birds (4 serves an average-sized family) with the stuffing of your choice (see recipes in Chapter 4). Sew the cavity shut with a needle and thread. Brown birds in butter. Place them in some sort of covered baking dish or pan. Add several onions, large carrot chunks, and whole potatoes—as many as your container will comfortably hold and your family can be expected to eat. Add 2 c. hot water, cover tightly, and bake at 325°F until the meat is tender (about 1½ hours). Cook giblets (not liver) separately. When giblets are tender, cut into small pieces and add them to the pot pie. When the pot pie is almost ready to serve, take out the meat and vegetables, and thicken the remaining liquid by adding 3 T. flour that has been premixed with ½ c. cold water. When your gravy has thickened, pour it back over the birds and vegetables and serve—or serve the gravy separately.
**ROAST SQUAB** Stuff the bird’s whole cavity with the poultry stuffing of your choice. Rub the outside of the bird with celery salt and pepper. Place in roaster, cover, and bake at 400°F for 45–60 minutes. During roasting, frequently baste the bird with drippings. At the halfway point, turn so that both sides will have a chance to brown.

I’ve been doing fairs every weekend this fall, sitting behind my card table laden with copies of my book, working hard on this new edition while waiting for customers for the older one. People who don’t know me are skeptical, hesitant when they see my hand-lettered, scavenged-cardboard sign, and multicolored, ringbound books with unprinted green cardboard covers.

Couldn’t be worth much, they reason, a homemade book.

If they’re curious enough to give me eye contact, I hand them the one-sheet brochure. Maybe a person pauses long enough to leaf through a sample copy. Perhaps he or she even buys one and carries it away—the expression on his or her face showing surprise at its weight. I watch the person going and I have to chuckle. Maybe I’ll be sitting here years later and we’ll meet again.

There’s such a big difference between the new readers and the old ones. The old ones notice my table, creep up, and study the situation and me. Maybe they begin, “I have this book. . .” talking so because they doubt that the dumpy, aging woman behind the table could possibly be the Carla they had imagined—so rumpled (from sleeping in the car) . . . and where are all her little kids? (My kids are too grown-up now for tagging along with me to fairs. They’re living with their own families, or off at college, or have their own weekend plans.) Eventually she, or he, hesitantly asks, “Are you . . . Could you be . . . ?”

I say, “Yes, I’m Carla.”

Or maybe they are able to recognize the person in the old photos of a younger me, now concealed behind aging flesh. Some people do. They greet me with a shout of acclamation, rushing up eagerly to tell how they got their first copy of the book, and their land, and what they learned to do on it, and what happened then. Often they buy the new edition and ask me to autograph it, or they go home and get their old one for that purpose.

I think of this book’s readers as “my people.” They’re my readers, at least, the people who live my (our) dream in flesh. Some people do. They greet me with a shout of acclamation, rushing up eagerly to tell how they got their first copy of the book, and their land, and what they learned to do on it, and what happened then. Often they buy the new edition and ask me to autograph it, or they go home and get their old one for that purpose.

I think of this book’s readers as “my people.” They’re my readers, at least, the people who live my (our) dream in all its tawdry chicken-plucking day-in-and-day-out fine print. They’re the people I’ve worked my writer’s lifetime to serve. I want to touch these precious, truly beloved readers—real beside me at last. So we clasp hands across the table. Or, if they look like huggable sorts, I come around the table and put out my arms, and we hug each other with genuine feelings of love. I know that a particular reader is someone who already knows me well and cares about me. She or he’s the person I’ve worked so long and hard to serve, visualized in my mind’s eye, talked to as I wrote and wrote and wrote this book over the lonely days, months, and years.

Those meetings with loving readers are always a beautiful experience—my reward! Then I know it’s all been worth it. And I’m again astonished, and humbled, to discover that a mere book can mean so much to people. The job of writing is indeed a special one. And the work truly is greater than the workman!

An extraordinary encounter of that kind happened one unforgettable day a couple years ago at the Missoula (Montana) County Fair. That time I did have several children with me, but they were all off watching the pig races. A couple came in the door of the Culinary Arts Building, where I’d just wound up a chicken-butchering demonstration. They were carrying a copy of the book, holding it together, out in front of them. They were both silently crying, unashamed, walking slowly toward me.

The audience for my chicken-butchering lesson had been very small. There’d been an article in the newspaper that I was at the fair, and the demo was in the fair schedule, but it obviously didn’t hold nearly the attraction of the pig races. Just as well. It was embarrassing to realize that most of the people I was talking to knew more about chicken butchering than I did. But there were also a few genuine novices there, for whom I was so grateful. They were the ones I’d hoped to help when I put the event on my program. I knew it wouldn’t be fun, but I’d been determined to do it. I knew nobody but me would ever have the gall to teach a chicken-butchering class. And that’s among the things people tell me they most often have to do for the first time, depending only on what it says in the book.

Before it started, while my audience waited inside, I had to remove the poor “subject” from its wire carrying cage and dispatch it out back of the building with a few of the “students” observing. As I had arrived in what I imagined would be a proper alley, I observed to my horror there were hundreds of dressed-up fair attendees strolling by the site. And the knife I’d been provided turned out to be so dull it was a considerable achievement merely to draw blood, to say nothing of managing an elegant and humane execution of the bird. I was also trying desperately to keep my bird’s head way down in the 5-gallon bucket I had available, so it wouldn’t escape to do a flopping, blood-splattering extravaganza before all those noncomprehending and curious eyes. That achievement by the bird would probably have gained it the sweet revenge of landing me either in jail or in an asylum.

Well, I did finally manage to get the job done and brought my headless bird back into the exhibition hall. There I demonstrated its immersion in scalding water, picked off its feathers, singed away the remaining hairs, and finally demonstrated how to cut it into frying pieces. I felt so relieved when it was all over. I sat chatting with some of the people who’d come to watch, autographing books, answering a few last questions about the fine points of chicken butchering.

That was when I saw the couple come in the door and head straight for me, bringing their beat-up old book for an autograph. They hadn’t bothered dressing up, or maybe they didn’t have any better clothes. They slowly approached, eyes fixed on me. I stepped away from the people I’d been talking to and waited until at last the middle-aged couple stood before me. They were a decade or two younger than I, but still gray and dusty, shabby, holding that frayed green-covered book out toward me as if it were their ticket to enter—as if it were something so precious to them. The tattered book was darkened by years of . . . Was it smoke from a wood cookstove in a small, poorly ventilated cabin? Did their lungs look like that inside? I wondered.
I smelled dope. They were both just reeking of mari­juana. They were both looking at me, silently crying, tears running furrows of wetness down their dusty cheeks.

What to do?

Like me, I thought, they were once so young and handsome, so full of hopeful dreams. Looking at them, I already knew the story: how they'd left a big city together years ago when they were young and moved to some version of the rural outback with such an optimistic, beautiful vision. How they'd struggled, worked, raised food, raised children, been scorned by some of their neighbors and their kids' teachers—and finally, perhaps, even by their kids. But they never gave up. And they still did have their acres—I hoped—and each other, obviously. And that beat-up, much-used old book.

Well, they were definitely more "my people," aroma and all, than those who sometimes show up—real-estate agent types, dressed to the nines, beaming at me, able to buy several more books to take with them, tickled pink with my role in their prosperity and, clearly, lifetime straight.

The couple stood crying before me.

I felt a sudden crushing emotion of shame. They'd taken it all literally, I thought. They actually went out and tried to live it—all of it. They stayed with it, never wised up, never went back to town as so many of the others had—others who bought the book and wrote me a Hooray-Carla-we're-back-to-the-land letter, but later—a year or two, or five—the book was in their garage sale. They were outta there.

I felt so guilty, so sorry for this couple. I started crying too, looking in their eyes and knowing all that, all the suf­fering they'd gone through because of keeping so loyal to the Dream. Always raising and butchering the dang chick­ens themselves instead of buying them ready-to-fry at the supermarket.

Should I be punished for articulating and promoting so hard, so costly, a lifestyle? Maybe I should be horse­whipped, tarred-and-feathered, dragged forever through a field of organic mud behind a stubborn mule in just retri­bution for setting their feet on that more rural path. How their parents who, years ago, must have planned an easier, more prosperous, more respectable life for them, must have been disappointed. Their parents probably hated me. I felt so guilty.

But I took a step toward them, toward the beauty inside them that radiated from under the shabby cloth, the aging skin, the trappings of poverty, the smell of burnt grass. Then they took the last step forward toward me.

We, all three, put our arms around each other, and cried and cried. We cried together with the bittersweet intensity of summing up a life's meaning in a moment: mine as writer, theirs as readers. We were three people made one through the mysterious magic of a stack of printed and bound sheets of paper. We were so close, and it was so beautiful.

After a moment, whatever it was we were doing was done. The tension broke. Our wordless solemnity and tears suddenly turned to easy chatter and laughter, the way people act when they're coming out of church after services. Then they told me their story. Sure enough, it was all just as I had figured—except they didn't want me to feel guilty. They were grateful for the vision and the guidance I'd given them!

Then the woman confided that she wanted to be a writer like me and asked my advice. I gave my blessing and what wisdom I could, for that's another hard path.

I autographed their book. I gave them the latest edition (they couldn't afford to buy it) and was promised some home-grown food in trade (which they later sent to me). Eventually it all wound down, and they left. But I'll never forget that day . . . that meeting . . . them. They left me a gift of canned jam and a searing emotional memory I'll never forget and never escape. Sometimes it's scary being that involved in people's lives.

Five years later, I see the woman's articles in homestead-genre magazines quite often. It makes me happy and proud for her. She keeps getting better. She'll be doing her own book someday, I reckon.

Five years later, I see the woman's articles in...

GOATS, COWS & HOME DAIRYING
723
wouldn’t move a foot when I tried to chase her, and she turned out to have a solid distaste for stanchions. Fifteen minutes later I was squatting in the middle of the barn holding crying Sara with one arm, trying to milk with the other, and admonishing the children and Thor by turns to be quiet. The chickens were in the manger eating the cow’s grain. At that moment Dolly yelled from the house that I drive her anywhere because her notion is to follow me, and if I get behind her she just stands there. There’s always a period of adjustment when a new animal joins your family. A cow has a different mentality from a goat. Cows are very steady animals. Once a cow gets a notion of how things are supposed to be, that’s the way she’s going to proceed, and it’s unreal for any mere human to try convincing her otherwise. But if you learn to yield a little to a milk cow’s preferences, she can be really loving and giving in her own way.

So now I gather up the milk bucket. I use a plastic bucket because it’s so much quieter—doesn’t rattle and ping and startle the animals or me out of our reveries. And I fill a jar or pitcher part way with warm water and put a rag in it, for udder-washing and seduction. Then I go directly from the house through the gate into the field. Nelly sees me and comes right away. It’s not good for milk cows to run. My father drilled that into me—never, never run a milk cow. Nelly used to run to me when she saw me, but that was when she was new and so nervous. When a 700-lb. cow runs up to you, that’s too much love. You’d really rather she walked up—just in case her brakes slip. But now as soon as Nelly sees me she starts coming, following me to wherever I decide to stop. That will be a flat spot inside the barn or in the field, depending on the weather. If I bring grain and the chickens follow, Nelly starts eating the grain along with the chickens. She’s used to them now. She has a much bigger mouth than the chickens. She’s used to them now.

The homesteading literature is somewhat slanted toward goats. Goats are small, and they are playful, mischievous, and fun. But I’ve had experience with both cows and goats and let me tell you—cows may not jump around, but still water runs deep, and they sure enough have an emotional life. This morning I was getting ready to milk number 108, now called Nelly. I’ve submitted to her disinclination for stanchions and discovered it a blessing. I finally realized that I couldn’t

INTRODUCTION

This chapter is dedicated to the discriminating woman who would rather own... a cow or a goat! September 1993. Almost done with the ninth edition. I am amazed at the sophisticated and widespread knowledge that exists these days among home-dairying people. Once, perhaps, I had a lot to offer here. I’m not so sure any more, but I’ve done my best to catch up on things and to update this section while staying within my time and space limitations. There are so many good books written about this area, so many opportunities for education and self-education, and so many dedicated dairy extension agents with information to offer. This chapter can now be thought of only as a place to begin. (Actually, the same can be said of every chapter in this book.) My hope is that I can still be of use—by providing a little information on just about everything and leads about where to find more.

Marietta, the shorthorn cow, got mastitis Christmas Eve. So from then until now (April 1974), we had no milking cow. We finally squeezed out enough money—$350—to buy a Jersey carrying her third calf, due to calve in August. She was number 108. I had a notion I’d go out and milk her for the first time and tell about the experience for the introduction of this chapter. I figured it would really be rapturous and poetical.

Well, that morning I couldn’t get out the door without an entourage of Becca, 4, Luke, 2, and Baby Sara, 11 months. And for some reason they were all in bad moods and Sara was crying more on than off. We arrived at the barn accompanied by our dog, Thor, who not only chases chickens but also thinks he must impress milk cows with his importance. A cast of about 30 chickens were with us, too, pursuing the grain can I was holding, figuring on sharing the cow’s feed.

Number 108 apparently had never been in the presence of whining children, a barking dog, or cackling, crowing, thieving chickens. She was wanted on the telephone, and I thanked God for mercifully giving me a release from my suffering.

When I returned to the barn after the phone call, I was alone because the baby was asleep in her crib, due to calve in August. She was number 108. I had a notion I’d go out and milk her for the first time and tell about the experience for the introduction of this chapter. I figured it would really be rapturous and poetical.

She had their tummies full of the cow’s grain, so they were off looking for something more exciting-fat bugs perhaps. And I’d locked the dog in the house. By the time the milking was over, number 108 had developed such an affection for me that she followed me back to the house and walked around it for the next 2 hours, mooing longingly.

The homesteading literature is somewhat slanted toward goats. Goats are small, and they are playful, mischievous, and fun. But I’ve had experience with both cows and goats and let me tell you—cows may not jump around, but still water runs deep, and they sure enough have an emotional life. This morning I was getting ready to milk number 108, now called Nelly. I’ve submitted to her disinclination for stanchions and discovered it a blessing. I finally realized that I couldn’t
Dairying

SELLING DAIRY PRODUCTS: There's a big difference between home-dairying and dairying in order to sell your products. Even in places where milk can be sold raw, licensing is required, and the nannies or cows must be carefully tested and kept free of brucellosis and tuberculosis. Do you have money to invest in a special outbuilding for dairying, or a cheese-making place? (You could sell stocks for financing.) Can you write a 5-year business plan? Have you studied your state's dairy laws? (In at least 21 states, for example, goat milk when retailed must be pasteurized—requiring an investment in equipment.) Have you talked to your dairy extension agent? That's somebody who's willing to explain everything, shepherd you through all the preparatory steps, guide you through the legal requirements for your building and equipment, and later regularly inspect for cleanliness and test your milk samples to be sure they don't contain bacteria or antibiotics. (Dairy production is the most heavily regulated and supervised food business there is.)

If so, then you're ready to start your dairy business. You could sell milk, cheeses, yogurt, maybe even meat and sausage products. But the more products you sell, the more start-up money you will need to build approved facilities. You'll also need a lot of marketing time and know-how—especially for selling goat's milk. Usually, the hardest part is finding the money to pay for everything you need for the start-up of a commercial operation. The easiest commercial dairy areas to get started in, are cheese-making in particular, and the special services and specialty products markets in general. (For example, whole milk with cream that rises to the top and that is home-delivered in bottles is coming back in some areas.)

But to sell fresh dairy products (as opposed to processed ones), you must have the highest possible sanitary standards. Milk direct from a cow is 100°F. In a commercial dairy the milk moves through hoses directly from the cow to a plate cooler that in just a few seconds chills the milk to about 38°F. Then it probably goes to a stainless-steel tank, then to a pasteurizing unit where bacteria are killed and enzymes are neutralized. Then it is separated into skim and butterfat. Then a sophisticated system mixes butterfat in again but only in the amount right for the particular product: nonfat, 1 percent, 2 percent, etc. Then the milk is homogenized, a process that breaks big fat globs into ones so tiny they can't get together and float to the top but remain evenly distributed in the milk. Then the milk is piped to a machine and put into containers. Some dairy farms can't afford all that equipment and prefer to be part of a co-op, so they can truck the milk from their holding tanks to a center for the rest of the processing. But, one way or another, most dairies get their milk from the cow to the grocery store within 48 hours.

Dairying, like many kinds of farming, is a hard business to survive in and an easy one in which to lose your shirt. Between 1981 and 1991, the amount of money that farmers in Washington State received for milk decreased by more than 20 percent, even though the retail price of milk at the store increased 27 percent. During that period a lot of the Washington's dairy farmers left the business.

Dairy farming has changed a lot since my grandfather's day, when cows ate grass in meadows and were milked by hand. The basic trend has been to get big or lose out. Washington is one of the top dairy states and one where there are still many medium-sized herds harvesting the rich coastal mainland grasses. Here an average dairy farmer markets $350,000 worth of milk each year from an average of 210 milking cows. That same farmer also has maybe 200 more calves, to be sold for beef, and heifers not yet come to milking age. Each year, the farmer will buy $175,000 of feed, especially hay. Washington's dairy farms are small compared to the average California dairy operation, where 1,000-5,000 cows are the industry standard.

So you can see why commercial dairying tends to be a sophisticated big business, and why so many small dairies have gone under. The industry, nationwide, is increasingly dominated by mega-dairies, each with over 1,000 cows—almost always Holsteins—bred for maximum production, fed for maximum production, and living computer-monitored lives designed to wrest every possible ounce of milk out before the cow goes to the hamburger line.

They work hard for a living—the cows and the dairy farmers. And their product, milk, is a wonderful food, a high-protein food that is far, far more pure (as best I can figure it) than almost any captured-in-the-wild food. Milk is the most monitored food in the food chain! And if you have a bit of land with enough room for a couple goats or a small cow, you can have your own organic milk, butter, ice cream, etc., from animals who were fed organic foods. Because what comes out is as pure as what goes in!

DAIRY INFO AND SUPPLIES
Caprine Supply offers a huge free goat supply catalog, including cheesemaking supplies: 800-646-7736; fax 800-646-7796; 913-585-1140; Box Y, 33001 W. 83rd St., DeSoto, KS 66018; caprinesup@aol.com; www.caprinesupply.com.
Cheesemaking Supply Outlet: call/fax 440-968-3770; 9155 Madison Rd., Montville, OH 44064; rmhcso@alltell.net.
CreamLine: This quarterly newsletter for small-scale dairy owners interested in on-farm processing also contains useful info for folks just making dairy products for
family use. It's packed with hard-to-find sources for small-scale equipment, facts on pasteurization, cheese-making, packaging, etc. It profiles successful small dairies and provides recipes for dairy products. Cost is $40/2 yrs; $2 sample copy. Contact: Vicki Dunaway; call/fax 540-789-7877; PO Box 186, Willis, VA 24380; ladybug@swva.net; www.metalab.unc.edu/creamery. Vicki has also published The Small Dairy Resource Book, a 56-pg. annotated bibliography of books, periodicals, videos, etc., on farmstead dairy processing: cheese, ice cream, butter—both production and marketing—which is first in providing small dairy info! To order a print copy ($8), go to www.sare.org/san/hdocs/pubs/ or call 802-656-0484. Vicki also publishes Home Dairy News.

Dairy Center Inc.: PO Box 2564, Ontario, CA 91762-6690; 909-628-4784; fax 909-627-8781.

Glengarry Cheesemaking & Dairy Supply offers equipment, supplies, etc., for making cheese, including molds, ingredients, and courses: 613-525-3133; fax 613-525-3394; RR #2, Alexandria, Ontario KOC 1A0, CANADA; morris@cnwl.igs.net; www.glengarry cheesemaking.on.ca.

Hoegger Supply Co. offers all a goatkeeper could need, reasonably priced: 800-221-4628; fax 770-461-7334; PO Box 331, 160 Providence Rd., Fayetteville, GA 30215; hoegger@mindspring.com; www.Hoegger goatsupply.com.

Lehman’s Hardware sells ready-made or custom goat and cow bells, each with a unique tone; milk pasteurizers; carved butter molds; milk cans; strainers; cream separators; butter churns; cheese presses; milk funnels and strainers; anti-cow kickers; milking stool, etc.: 888-438-5346; www.lehmanns.com.

Nelson-Jameson is a “food and dairy supplier”: 800-826-8302; www.nelsonjameson.com.

New England Cheesemaking Supply offers equipment and info to make and sell cheeses. Free catalog: 413-628-3608; fax 413-628-4061; PO Box 85, Ashfield, MA 01330; www.cheesemaking.com.

Small Dairy Project/Second-to-None Dairy Supplies sells and loans customers small-scale dairy equipment: 603-927-4176; HC 65, Box 45, Bradford, NH 03221; nunsuch@conknet.com; www.nunsuch.org.

Milk a Sheep? Cow? Goat?

If you’re just getting started, your first big decision is what kind of animal to milk. Around the world not only cows and goats are milked, but also sheep, reindeer, camels, water buffalo, and others. Any dairy animal is a miracle of efficiency. Grass, vegetables, grain, water, and salt go in one end. Milk, baby animals (meat), and manure to build up your garden soil come out from various other locations. There is no waste. She can be purchased reasonably, moved from location to location—and will love you! But what kind to buy?

**Sheep:** How about dairy sheep? Yes, you can milk sheep! They have wonderful milk. See Chapter 11 for more on this. Nevertheless, most home dairiers will choose a goat or cow.

**Goat or Cow?** Worldwide, goats are milked more than cows. Figured by percentage of body weight, a goat is more efficient and produces much more milk than a cow. On the other hand, cows produce much more meat from their surplus calves and can get along better on a basic pasture/hay feed. Any cow eats much more than a goat does and requires hay in quantity in winter, whereas goats can get along on less hay and quite a bit of vegetable food and brush. Cows give more milk per animal by far, and their cream can be more easily separated to be made into butter, whipping cream, or plain cream. A milk cow can be bred annually to a beef-type bull in order to have a beefy calf for eventual slaughter.

**Expenses.** You can keep about 5 goats to 1 milk cow as far as the expense of feeding goes. You won’t have near the struggle keeping the cow out of the garden as you would with the goat. On the other hand, if 1 goat dies you haven’t lost anything. Around here, a home-dairy-type Jersey could sell for $800. A Holstein would cost much more—$1,000 for an average dairy-quality Holstein, $1,800 for a good cow that’s bred-back to a good bull. If you get offered a cow for $500 or less, it’s somebody’s cull, giving maybe 2 gal. per day. The least expensive cow would be a first-freshening (“to freshen” means to calve and give milk) heifer, but if it’s your first time, you might be best off starting with a cow with some experience.

The best cow is one that isn’t too old and is already re­bred and trained to milk. How much milk should she give? Twenty years ago when I was first writing this book, a cow who gave 6 gal. per day was super. Dairies now have cows that are giving 12 or 13 gal. per day. That’s how much dairy cows have been selected upward. But these super Holsteins are more prone to mastitis now than they used to be. And that’s a ridiculous amount of milk for a family cow unless you’re going to raise other animals on the surplus. Dairies usually sell off a cow as a cull when she gets down to 4 or 5 gal., and that’s still a lot of milk for a family. One of the small, old-time home-dairy breeds, like a Jersey, may be more what you want. It’s simplest for you if she’s bred and in at least her second lactation.

Incidentally, by the time you get a cow or goat home, through the period of adjustment, and allow for exaggerations on the part of the seller, she may turn out to be giving a little more than half what you were promised. Which still can be a lot of milk.

Dairy-type bull calves now sell for $140–$185, a beef-type calf for $185–$250. If you bought from the dairy itself, you might get one for $95–$110. It’s hard to find a young heifer calf for sale. People hang on to them. A cow grows up to weigh between 700 and 1,500 lb., depending on the breed. A bull can weigh around 3,000 lb. That’s a lot of meat compared to a goat.

The price of goats is much less than that of cows, but is still much more than it was 25 years ago. Back then, a non-purebred milking nanny changed hands for as little as $5, when you could get somebody to take one. Now a registered show-type milking nanny might sell for $100–$150, a grade milker for $70–$75, a young grade doe for $35–$65. Kids back then were generally given away. Now at the livestock auction, a 2- or 3-month-old buck may sell for meat for $25, a doe for $35. A year-old goat for butcher might bring $75–$110 from the ethnic meat buyers.

But livestock prices are volatile, responding mercilessly to the laws of supply and demand. I’ve lived long enough to have seen them take amazing crashes several times. I remember one such time—February 1, 1974—when the bottom dropped out of the beef market, and beef-type bull
The Land Factor. Whether you have a cow or a milk goat (or goats) is a very individual matter and depends a lot on what kind of land you have, as well as on how much money you have to get started and your personal preferences. Some people get really hot arguing one against the other. I started out with goats because I started out poverty-stricken on 3 acres and had a chance to get the goats at $5 a head. I’ve had as many as 20 at one time.

If you have a brushy cliff behind your house and just enough flat land for a vegetable garden, I’d say get a goat—it would thrive. If you are planning to homestead in dense timber where there is no open, grassy meadow, don’t buy a cow. You’d have to buy hay year-round for her because you wouldn’t have enough grass. Get goats. Their instinctive feeding habits are like those of a deer. By preference they eat twigs instead of grass, so they’ll be delighted with a forest and will help make a clearing for you. They like to eat the young tips of trees and bushes—just the way you’d protect your orchard!

If you have a nice alfalfa pasture and plenty of capital and you’d like to raise baby calves and pigs and lots of chickens, a cow would be very sensible. If you get a cow, you raise calves and dine on beef-steak instead of goat-burger. But how much land for a cow? You need at least 1 well-watered, good green acre for her grazing, either all at once or divided for rotation. Another lush acre will grow her winter feed, since an acre can grow almost 2 tons of hay and that’s how much winter hay she’ll need. With luck you can also graze her on her hay field—maybe the month of March before it seriously gets going, and then after your last hay cutting is off in August and September. A further eighth of an acre of garden will grow lots of winter veggies for her.

Goat’s Milk vs. Cow’s Milk. Like I said, I think any animal that shares the fruit of its body with us, be it milk or meat, is wonderful. I think it’s disrespectful to cows to get too prejudiced toward goats. And by the time you’re done reading this dairy section, you’ll see that I love goats, too, just as much as any confirmed goat-lover does. The fact is that milk is milk, and it’s food, and that’s the important thing.

A poor goat in her first lactation may give only a couple of cups a day. A prime milk goat may give as much as 5 quarts a day. A small Jersey cow will give 2–4 gallons a day. Really fresh goat’s milk tastes very like cow’s milk. It does develop a strong taste more rapidly after that, but there’s no need to drink old goat’s milk unless you’re trying to get cream to rise to the top of it. In that case you need to let it rest a few days. Don’t judge fresh goat’s milk by canned goat’s milk. That stuff is pretty awful.

Goat’s milk is prehomogenized like store milk, although given enough time some cream will finally rise to the top. You can skim it off with a dipper and have it on something for a real treat. Cow’s milk is fun because the cream rises fast and clearly to the top, so you just skim it off and there’s your whipping cream and cream for butter-making and cream to go in a pitcher on the table to pour over the strawberries. Some people struggle to make butter from goat’s milk. I did, too, and made it. But I think the most sensible thing, if you’re going to use goat’s milk, is to just plan the menu around whole milk the same way you would if you were living on reconstituted powdered milk and you couldn’t afford to buy cream or butter—only this way is so much better because the cream and butter is there—you’re eating it—it’s just not separated out so you can see it.

Goats

You can raise goats for fun, for milk and/or meat, or to make a living. Here are some commercial options for goat keepers:

1. Use nanny goats to raise calves (25 goats can raise their own offspring plus 25 to 35 calves).
2. Sell milk from a goat dairy (you need pasteurization and bottling equipment, a big market reasonably nearby, and a willingness to work hard and constantly). You can get extra income by selling kids for meat at Easter time. There are hundreds of prospering 50–150-doe goat dairies in the United States, even some 500–900-doe dairies.
3. Manufacture goat cheeses: blue, caerphilly, camembert, cheddar, chevre, feta, semi-aged, soft-ripened, shepherd’s, tomme, and capriano are all classic goat cheeses.
4. Sell fresh goat’s milk curd (used in sauces and for making cheese—in 1988 goat curd sold in New York City for $6.98/lb.), and goat yogurt (sells for more than regular cow yogurt).
5. Sell goats for meat (to the fancy restaurant trade) and for fine leather. This works well for people with a going grassland operation of sheep and/or cattle because meat (and/or Angora) goats eat some plants that sheep and cattle don’t, and the three animals pasture well together.
7. Train wethers (castrated male sheep) to pull, either alone or in a team. One can pull a small cultivator or a light wagon loaded up to 2 times his weight. He should be taught to lead at 2 months, be halter-broken by 6, harness-broken by 8, pulling loads by 10. Use
verbal commands as with oxen. Dairy-goat suppliers sell goat harnesses and carts.

GOAT INFO: Raising Goats for Milk and Meat, by Rosalee Sinn, is available from Heifer International: 1015 Louisiana St., Little Rock, AR 72202: 800-422-0474; www.heifer.org. This spiral-bound training manual has been used worldwide to teach goat care. It’s suitable for 4-H. You might also read Practical Goatkeeping by Jill and John Halliday (1990); and Raising Milk Goats Successfully by Gail Luttmann (1986). Older classics are Raising Milk Goats the Modern Way by Jerry Belanger; The Goat Owner’s Scrap Book by Dr. C. E. Leach; Management and Diseases of Dairy Goats by Samuel Guss, DVM, and Fundamentals of Improved Dairy Goat Management by Robert A. Jackson, DVM, updated by Alice G. Hall. One Day with a Goat Herd by C. J. Stevens is good for beginners. Your Goats is G. Damerow’s 172-pg. guide to raising and showing goats, including how to buy, raise, choose a breed and equipment, etc. The Illustrated Standard of the Dairy Goat by Nancy Lee Owen covers buying, breeding, showing, and milking.

English books are All About Goats by Lois Hetherington (1992) and Goat Farming by Alan Mowlem (1992). Mowlem’s book covers goat keeping in developing countries and exotic/tropical goat diseases. It’s available from The Smallholder Bookshop (44-1366-500466; www.smallholderbooks.co.uk).

The Pack Goat, by John Mionczynski, explains the use of goats as pack animals. These bright, cooperative animals are good for rough trail hiking. A goat can carry a load that’s 20 to 40 percent of its body weight. Life in the Goat Lane by Linda Fink covers shows, breeding, kidding, etc.

MAGAZINES, NEWSLETTERS, STORES, CLUBS

American Dairy Goat Association offers a wide choice of books and videos on goats, and it’s the biggest registry for the six major dairy breeds. It publishes a directory plus info handbooks and has a question-answering service: PO Box 865, Spindle, NC 28160; 828-286-3801; fax 828-287-0476; adga@adga.org; www.adga.org.

American Goat Society also registers main dairy and pygmy goat breeds and trains judges: 543-349-4709; PO Box 330, Broad Run, VA 20137; office@americangoatsociety.com; www.americangoatsociety.com.

Boer Goat and Meat Goat On-Line Magazine is a busy commercial site with announcements, advertisements, a breeder’s directory, and articles: www.boergoats.com/.

Cornell University’s web info at www.ansci.cornell.edu/extension/marketfact1.html advises on starting a meat goat operation. Additional info is offered at two other Cornell sites. (To access these sites use the same address, substituting “fact2” and “fact3.”) They also offer an Ethnic Calendar and the Empire State Meat Goat Producers Ass’n: www.ansci.cornell.edu/extension/esmpga.html.

“Cyber Goats,” at www.cybergoat.com/, is a busy website that offers classified ads, breeder’s links, auction notices, list of caprine vets, breed lists, online auctions, national breed show announcements, and links to various breed talk lists.

Dairy Goat Journal has served goat owners since 1916: 800-551-5691; fax 715-785-7414; W11564 Hwy 64, Withee, WI 54498; $21 for 6 issues/yr; $35 for 2 yrs (12 issues); csymag@tds.net; www.dairygoatjournal.com.

(The) Goat Farmer calls itself “the largest circulation goat magazine in the world,” the only professional magazine dedicated to goats only, and the one magazine which takes an international overview of the goat industry, largest collection of goat articles on the web, online A-Z of goat diseases, poisonous plant list, and free entry in their breeder directory: PO Box 641, Whangarei, NEW ZEALAND; thegoatfarmer@caprine.co.nz; www.caprine.co.nz.

(The) Goat Magazine is an all-breed goat periodical “for the serious goat breeder as well as those with just a few goats.” Topics include goat health, beginner’s basics, goat nutrition, pack goats, guardian animals, reader experiences, breeder directory, and upcoming goat events. Cost is $24 for 6 issues/yr, each 72–76 pp. A sample issue costs $5: 830-789-4268; fax 830-789-0006; 2268 CR 285, Gillett, TX 78116; editor@goatmagazine.com; www.goatmagazine.com.

Homesteader’s Connection is a 24-pg, newspaper-format bi-monthly. It covers homesteading and simple living, featuring dairy and meat goats, small livestock, gardening, alternative energy, etc. Cost is $18/yr; sample $2: Andy Oliver; 915-653-5438; PO Box 5373, San Angelo, TX 78902; www.homesteadersconnection.com.

Institute for Goat Research offers courses and demonstrations: Box 730, Langston, OK 73050; 405-466-3836.

Jack & Anita Mauldin Boer Goats is a website that shares Boer goat info and some general goat info also. Articles on “Goat Birthing from Beginning to End,” “State and Federal Scrapie Requirements Program,” etc.: 2400 County Rd 100, Georgetown, TX 78626; jack@jammauldin.com; www.jackmauldin.com.

Meat Goat Monthly News and/or Ranch & Rural Living Magazine ($25 for 12 issues/yr) covers meat goats, the wool and mohair industry, and goat shows: 915-655-4434; fax 915-658-8250; PO Box 2678, San Angelo, TX 76902; 915-655-4434; info@ranchmagazine.com; www.ranchmagazine.com.

GOAT VET RESOURCES: Fundamentals of Improved Dairy Goat Management, by R. A. Jackson, DVM, and Alice Hall, combines the know-hows of a goat keeper with the expertise of a vet. Goat Health Handbook provides diagnosis/treatment info for goat diseases. Both are available from Winrock International Institute for Agricultural Development, 38 Winrock Dr., Morrilton, AR 72110; 501-727-5435; receptionist@winrock.org, $8.50. The Goatskeeper’s Veterinary Book by Peter Dunn, B.Vsc. (an English book), and The Management of Diseases of Dairy Goats by Sam B. Guss, DVM, an older book on this subject, are available from Caprine Supply. You may find Natural Goat Remedies,
by Karen Ray, also helpful: 616-621-6000; 59520 Springdale Dr., Hartford, MI 49057; www.karenelizabethray.com.

DIETARY SUPPLEMENTS: I deeply appreciate the nutritional supplements I take. Your hard-working dairy animals may benefit from some, too. You can buy herbal supplements, vitamins, minerals, colostrum, milk replacers, medications, etc., from Nutritional Research Associates (800-456-4931; Box 354, South Whitley, IN 46787) and Vita Stress (360-794-9663; 12119 Bollenbough Hill Rd., Monroe, WA 98272).

A footnote: I enjoy noting a resemblance between people and their favorite animals. (I've always had Border Collies, or a Collie/Husky-cross—strictly working animals for this workaholic woman!) Is that true of the chosen milk animal also? Goat keepers do seem to produce far more books and magazines than cow keepers! Is that because goat keepers, like their inquisitive charges, are a more paper-loving (literary?), or more social and lively group? Are cow keepers, like their bovine milkers, more sedate and reserved, with less appetite for newsprint?

COURSES ON GOAT KEEPING: You can study "Dairy Goat Production #225" by correspondence. Write Independent Study, University of Guelph, Guelph, Ontario, Canada N1G 2W1. The course teaches breeding, feeding, housing, herd health, and kidding. Slides and tapes included. Incidentally, this is the best mail-order education I know of on food production skills in general. The program is managed by the Ontario Agricultural College, (519) 767-5050, fax (519) 824-9813. You can take courses just to learn or for a diploma. There are dozens of possible choices from "Making Maple Syrup" to "Greenhouse Management" to "Livestock Biology and Butchering" to "Marketing for Small Rural Enterprise." Their program combines manuals, videos, tapes, assignments, and a telephone counselor.

You can also enroll in the Dairy Goats correspondence course from Pennsylvania State University, 307 Agricultural Administration Bldg., University Park, PA 16802, for 9 lessons covering dairy-goat origins, characteristics, feeding, care and management, breeding, housing, and equipment. In-person courses and demonstrations are offered by the Institute for Goat Research, Box 730, Langston, OK 73050, (405) 466-3836; the Dairy Goat Research Facility, University of California at Davis, Animal Science Dept., Davis, CA 95616, (916) 752-6792; and also at the International Dairy Goat Research Center, Prairie View A&M University, Box 4079, Prairie View, TX 77446, (409) 857-3926, fax (409) 857-2325.

Barney Harris, Jr., Extension Dairyman at the Florida Cooperative Extension Service, 203 Dairy Science Building, University of Florida, Gainesville, FL 32611, (904) 392-1958, is eager to send people goat information. Or you could study there in the Dairy Science Dept., where he is a professor, and get a degree in dairying!

GOAT ASSOCIATIONS: There's the American Dairy Goat Association, Box 865, Spindale, NC 28160, (704) 286-3801, a registry for the 6 major dairy breeds (the biggest). It also puts out a directory plus informational handbooks and has a question-answering service. Canadians can join the Canadian Goat Society, Box 357, Fergus, Ontario, Canada N1M 3E2. If you want to research goats, try the International Dairy Goat Registry, Rt. 1, Box 265-A, Rossville, GA 30741, which registers all breeds and also offers a library and archive.

GOAT-KEEPERS’ SUPPLIES: Hoegger Supply Co. has a $1 catalog that offers everything the goat keeper could possibly imagine needing. Write P.O. Box 331, Fayetteville, GA 30214, (404) 461-4129, or (ordering only) (800) 221-GOAT. There's also Caprine Supply, Box Y, DeSoto, KS 66018, (913) 585-1191.

GOAT WORDS: I’ve heard you shouldn't use “billy” and “nanny”—you should use “buck” and “doe” instead. But “nanny” is also commonly used and the goats don't care! I hate to hear a non-pedigreed goat called a “scrub” though. It really puts her down unnecessarily. The word “chevon” means a goat intended for meat, or goat meat itself. A “wether” is a castrated male goat. "To kid" is to give birth, when speaking of a goat.

Getting Started with Goats

HOW MANY GOATS? Let me deal in conservative figures in case your goats turn out to be average or worse. Such a goat gives about 3 qt. milk per day. You’ll need 1 qt. per day to feed her kid, and more later, leaving only ½ qt. or so for your family. Yearlings won’t give even that much. They aren’t as large as full-grown goats and their teats and bags are smaller. At one time I milked 2 mature nans and 2 yearlings. I got only about ½ gal. per day, and that barely supplied the 2 nan kids that I was feeding plus our 4 children, me, and Pa. Now, as I write this section about goats, I’m milking 7 goats and that includes some really good ones. I get about 6 gal. per day. With this supply I always have plenty for the family, for making butter and cheese, and for raising 2 pigs. You really can’t have too many does. You can get them to adopt a calf or a bum lamb or let them raise their own kids for meat or market crop if you don’t want to bother milking them. If you feed a milk goat really well, including vegetables and grain, she’ll give more milk and can be milked for as long as 2 years on one freshening. The basic rule of thumb though is that you need 1 goat per person in your family in order to have all your dairy product needs met.

COMPANIONSHIP: Goats need companionship to be happy. But it doesn’t have to be another goat. A sheep, a cow, or your children can serve the purpose. Chickens can’t, though. A chicken just does not have it—except to another bird. Dynah Geissal, whom I am honored to call friend, and who regularly writes for many of the best homesteader magazines, advises: “A goat is a herd animal. If she must live alone, you will become her herd. This can be fun sometimes and maddening the rest of the time. She will get along with other livestock, or even a dog, if there are no other goats, but she is happier being one of a goat herd.”

By the way, Dynah generously shared her wisdom for many parts of this section on goats. You’ll find that she and I don’t always agree on the details, but she may be right and I wrong, and I wanted you to benefit from her experience.

WHAT AGE TO BUY? Says Dynah Geissal: “Buying a kid has some advantages: you learn while she learns, but you’ll wait a long time for milk. An older doe who is past her prime, but still in good health, may be a good bet. If a goat owner shows you an older doe who has been a special favorite, a good milker, and a good mother, you may have found a goldmine. You may be inexperienced, but your older doe is not.” Let me add that a yearling usually doesn’t produce well, but if she has good genes, she probably will.
Questions to Ask Before You Buy a Goat

1. What breed or cross is she?
2. How old is she?
3. Is she bred?
4. To what kind of goat?
5. When will she freshen?
6. How many times has she kidding before?
7. How many kids did she have? (Goats can have anywhere from 1 to 4. I had a goat who had 3 every time.)
8. Or, how long has she been milking?
9. What is it like to milk her? (Try it yourself, if possible.)
10. How much milk does she give?
11. How many teats does she have?
12. Does she jump fences?
13. Is she hard to catch?
14. Does she bite or butt other goats?
15. Has she had a distemper shot?
16. Are there tumors or abscesses in her udder?
17. Will she lead?
18. Can you watch her being milked? Examine her milk for signs of mastitis: strings, clots, blood, etc.
19. Have a look at her parents if she's young, at sisters and brothers if she's older, to view her wider gene pool.
20. Ask her owner to show you how to do hoof trimming and where stud service is available.

NOTE: Tuberculosis and brucellosis are rare diseases but are worth taking care about because they can infect humans through the milk. Buy animals that are guaranteed free of these or get them tested yourself before drinking any milk.

Your goat will give more milk each freshening up to age 6 or 7, with the years 4–6 being usually her highest production time. But with good care she'll keep freshening and milking well right on to age 10 or older.

Breeds: I won't state a preference among the full-size dairy goat breeds. They're all wonderful. But individuals vary. There are more than 50 goat breeds (more than 200 worldwide). Visit the website at Oklahoma State U. for profiles on each one: www.ansi.okstate.edu/breeds/goats/kinder/index.htm.

Boer: These stocky, muscular, meat-type goats were developed in South Africa in the '30s. They came to the U.S., by way of New Zealand, in 1993. They are most common in the Ozarks, Southwest, and Texas where they clean up brush and are marketed for butcher (best prices near Moslem holidays and in winter). International Boer Goat Ass'n (IBGA) membership info is available from Casey: 877-402-4242; PO Box 310, Bonham, TX 75418; ibga@netexas.net. Boer Goat Breeders' Ass'n of Australia offers literature and info, registration, etc.: (02) 6773-5177; fax (02) 6772-5376; c/o ABRI, Univ. of New England, Armidale, NSW 2351, AUSTRALIA; boer goat@abri.une.edu.au; boer goat-une.edu.au.

You can buy Boers from Bill and Nancy Hatton: 719-683-2556; 25945 E. Farm Rd. 48, Springfield, MO 65803; 417-833-3790. Or Meryl Winsten, Sunnytimes Dairy Goats, PO Box 19875, St. Louis, MO 63144; rhibbs@msn.com. Or Sheradee Peyton, 4496 N. 172nd, Walkerville, MI 49459; scottpeyton@hotmail.com.

Kiko. This New Zealand meat goat was imported to the U.S. in 1991. Dr. An Peischel has an outstanding herd: 530-679-1420; fax 530-679-1430; PO Box 29, Rackerby, CA 95972; kiko@inreach.com; www.home.inreach.com.

Spanish. This is the goat equivalent of the beef cow, a meat rather than dairy breed. Spanish goats are tough, thrifty, and hardy. They may be kept in flocks of 350 to 400 does if you have lots of pasture and some Pyrenees dogs or equivalent to keep coyotes and wild dogs off. Available from 8-Mile Ranch, Jim Willingham, PO Box 1828, Uvalde, TX 78802-1828; 830-278-3884.

Dairy Goats

Alpine. Alpines come in a variety of colors and patterns. French Alpines were very good milk producers for me. Alpines are Dynah's favorite breed: "They are independent, quiet, hardy, and give large quantities of milk. They are friendly and affectionate, yet go about their business when you are not working with them." Hazel McTeer raises both Alpine and Saanen dairy goats: 1753 E. Farm Rd. 48, Springfield, MO 65803; 417-833-3790. Or Merryl Winsten, Sunnytimes Dairy Goats, PO Box 19875, St. Louis, MO 63144; rhibbs@msn.com. Or Sheradee Peyton, 4496 N. 172nd, Walkerville, MI 49459; scottpeyton@hotmail.com.

La Mancha. No ears and full size means it's a La Mancha, a great milking breed. Saanen, French Alpine, and Toggenburgs have a similar size and milk production, erect ears, and are of Swiss origin.

Nubian. Nubians are the same on size and milk production as LaMancha, but have long, drooping ears. They're from Africa and withstand heat well. They have good dairy temperament. Available from Vickie Liguori; 540-377-2530; 334 Old Providence Rd., Spottsville, VA 24476; meadobrk@cfw.com.

Oberhasli. This is a relatively new breed of full-size Swiss dairy goat. They're available from Kim Emery, PO Box 478, McEwen, TN 37101; 931-582-3134; emery@mcwenc.net. Or from G'day's, 2600 Phipps Rd., Applegate, MI 48401; 313-633-9528. Or Audrey K. Hallowell, 2479 Newcomer Rd., Chambersburg, PA 17201-9397; 717-264-4786.

Saanen. These are among the largest and most popular of the Swiss breeds. Mature does weigh 135 lb. or more and
Angora goats. Other states such as Oklahoma, Arizona and South Dakota have been kept for their luxurious fiber for centuries. They are known as Angora.

Toggenburg. Toggenburs are always some shade of brown with white markings on the face and rump. Among the goat breeds that I've had experience with, Toggenburgs far and away impressed me the most. Mine were persnickety aristocrats. It was an old Toggenburg that usually bossed the herd. Toggenburs had very definite notions as to how I ought to handle them and were more independent than the rest, but, wow, did they ever give milk. They were also in the front line when it came to fighting coyotes. The Toggenburgs always got the most blood on their horns.

Fiber Goats

Angora. Angora goats originated in the Himalayas. At this point I am interrupted by a polite but testy letter from writer-about-Angoras Sue Drummond, who did me the favor of stating: “I have no idea where you got your information on Angora goats, but most of it is way off base. The following is what I would suggest you print about Angoras.” So, yours-truly-always-and-humbly-grateful-to-be-corrected cut out all the “off-base” stuff, and here's the word from a true expert instead! Bruised feelings aside, I'm honestly grateful anytime somebody who knows better takes the trouble to straighten me out. Now here's Sue:

“Angora goats originated in the Himalayas and have been kept for their luxurious fiber for centuries. They are white, long-haired goats that produce mohair. Angora goats are not kept for their milk. Their hair grows around one inch a month all year round. They are the most efficient producers of fiber of all animals except for a few breeds of wool sheep. Angora goats are sheared twice a year in the spring and the fall. An adult doe produces from 10 to 16 lbs. per year.

“Mohair is valued for its properties of sheen, loft or fluff, strength, fire resistance, soil resistance, and its ability to take dye brightly. Raw mohair can be processed for hand-spinning by washing and rinsing it in 140°F water using dish-washing liquid. Care must be taken not to agitate the hair too much during washing and it must not be dried in a dryer. The mohair can be carded and spun and dyed in the yarn or dyed before spinning.

“Texas is the largest producer of mohair in the world after South Africa. Texas is the home of around 2 million Angora goats. Other states such as Oklahoma, Arizona and New Mexico also have substantial Angora goat populations and Angoras are found in nearly every state in the United States.

For more info on Angoras, contact the American Angora Goat Breeder’s Association: 830-683-4483; PO Box 195, Rocksprings, TX 78880. Ranch Magazine prints articles about Angora goats: PO Box 2678, San Angelo, TX 76902. And check out The Complete Angora Goat and The Angora Goat Book & Guard Dogs, a guide for beginning Angora goat raisers by Jean Ebeling, $26 (postpaid): 5443 CR 401, Marble Falls, TX 78654. And the Northeast Angora Goat Breeders Ass’n, Bob Ramirez, Pres.: Keldaby Farm; 413-624-3090; 12 Heath Rd., Colrain, MA 01340. Cerulean Farm offers Saanen dairy goats, Angoras, Anatolian shepherd guard dogs, and spinning equipment: PO Box 100, Harrah, OK 73045; 405-356-2612; bluemohair@earthlink.net. Cashmere. These goats are another fleece type. They produce “cashmere,” which is not the same thing as the mohair that angoras produce. Cashmere is a fine underdown that cashmere goats grow between the longest day in summer and the shortest day in winter. Their body hormones are triggered by shortening day-length to grow it. They shed the cashmere in the spring, unpredictably any time between January and May. You can’t comb the down out until it becomes loose. If you leave combing too long, you’ll lose it. The finest cashmere goats are said to be in China, but they’re also grown in Turkey, Iran, Iraq, New Zealand, and Australia. Some are being imported into the United States.

Cashmere goats are available from Cashmere Goat Registry of America: 219-784-2989; 22819 Stanton Rd., Lakeville, IN 46536. Or Flying M. Manor, Sarah Mace; 920-836-2769; 3788 W. Breezewood Lane, Oshkosh, WI 54904. For more info, contact Northwest Cashmere: Carole Laughlin; 503-625-8816; 21935 SW Lebeau Rd., Sherwood, OR 97140. Or International Cashmere Co.: 614-493-2401; 614-493-2595; PO Box 845M, Piketon, OH 45661. There are three cashmere processing plants in the U.S. (eight in the world). One is the Forte Cashmere Co.: 21 Eliot St., South Natick, MA 01760; www.Cashmere.com. Forte prefers clean white cashmere fiber, the longer and finer the better. More info is in the Cashmere Goat Manual, which started as a project for the El Paso County 4-H Club. It’s $10 from Jim Osborn, 3585 Spazat Rd., Monument, CO 80132; 719-488-8860. And read Angora Goats the Northern Way (1988), by Susan Black Drummond; and Angora Goat and Mohair Production (1993), by Maurice Shelton. Or contact the Australian Cashmere Growers Association: call/fax 03-9629-2390; PO Box 380, Kellyville, NSW 2155, AUSTRALIA; cashmere@acga.asn.au; www.cashmere.com.

Nigerian Dwarves. These little spotted or patterned, naturally horned, dairy goats come from West Africa. If milked, they give about ½ gal. per day. They will mate all year round and can be bred every 8–10 months. Kathy Claps wrote me: “This is a small breed, as small as the Pygmy, and it has a more refined, dairy-type conformation. They are found in a great variety of colors and milk quite well for their size.” The American Nigerian Dwarf Dairy Association is the national breed club: PO Box 96, Monticello, NM 87939. Or contact Penny J. Tyler: Tupence Nigerian Dwarf Goats, PO Box 799, Allyn, WA 98524; 360-275-4236; tupence@htcc.com.

Pygmy. An adult goat that never gets more than 20 inches high is a Pygmy. They can be milked but only give about ½ as much as a full-sized goat.

Or you could have a cross between any 2 or more of the above breeds.

Moving Your New Goat: When you buy a goat, find out how the current owners get her places. Do they lead her with a rope or shake a can of grain in front of her nose? This information immediately becomes very important. It’s nicest if she’s broken to lead. All my new or naughty goats wear collars with a short rope attached. It makes it easier to grab them and get them started leading. I don’t like the grain-can bit because with a big herd and...
some calves and horses in there too, I'm liable to get trampled. But for just a few goats it's a good technique to train them to follow as you walk along holding the can, occasionally shaking it so they can hear the scrumptious noise. Stop and give them just a bite before they start or whenever they look like they're losing faith in you and the can. Or you can grab the horns and just drag them along with somebody behind to push — a time and place when horns are useful, but still a desperation measure. Or you can carry them — another desperation measure.

**The Butting Order:** Goats are rough on each other. They occasionally even bite each other. A big goat with big horns will bully a new goat, especially a small one, and keep it away from the food. If you're planning to have just 2 goats and have small quarters for them to live and eat in, it would make sense to get 2 goats that are dehorned or naturally hornless. And make that either 2 yearlings or 2 adults while you're at it. There are exceptions, though. I had a yearling once that was so mean to the big goats I had to sell her. Generally, though, once a herd gets established and used to one another, they all live together fairly peacefully. Given time, any combination of goats will become pals. A boss goat always emerges, too, usually a big, older nanny. She will lead the herd out to feed in the morning and back home at night. But goats aren't necessarily charitable to the weak. If a goat seems hurt or sick, put it in a pen by itself with water, straw or hay bedding, and good food. The other goats probably wouldn't let the sick one get its share of food and might persecute it to boot.

**Fencing, Housing, and Food**

**Fencing for Goats:** The biggest problem with any goats, male or female, is controlling them. They can jump over, crawl through, or squeeze between — and they can do terrible damage terribly fast if they get where they don't belong. Wrap the trunks of your fruit trees with chicken wire 6 feet high if you have goats. This keeps the goats from eating the bark. If the goats are sticking their heads through and getting stuff they shouldn't, fence them in with chicken wire. Keep them well fed so the garden won't look so tempting. Even so, they may get out just for the principle of it.

Dynah Geissel wrote me: "Just as you would prepare a place for a new baby, preparing a place for your new livestock will save a lot of anxiety and confusion when you bring them home. First, check your fences. Each goat should have access to ¼ acre. The minimum fence height is 4½ feet. A determined goat can clear a 6-foot fence, but if she is properly cared for and has not established bad habits, 4½ feet will generally restrain her. Obviously the fence should not lean out. Also, if the top is wire, there will be no 'step up.' There should be no vertical gap greater than 14 inches and no horizontal gap greater than 8 inches. You'd be surprised what a goat can slip through.

Don Fallick wrote me: "Rail fences for goats don't work well, unless the rails are so close together that a goat just can't get through. Even then, the goats can see through, and may jump right over even an 8-foot fence. But goats (and deer) won't jump a fence they can't see through or over. Many goat breeders have found a solid wood fence 5 feet tall keeps their goats at home. If you decide to build a solid goat fence from slabs, nail the vertical slabs to horizontal stringers, with the bark side away from the goats. Goats love to chew on bark and can loosen up even the hardest driven nail just to get at the tiny piece of bark under it. If you intend to fence goat kids, make the top panel inward-sloping, or make it of chicken wire, to prevent them from caroming off the corners and flying out.

"Goat fences need gates that hook shut with spring-lock hooks. Besides being able to jump unbelievably high, goats have prehensile tongues, and can unlock most standard latches, even including spring hook latches. Goats have prehensile lips and can reach and unlock latches that many people have trouble with. I once rigged such a latch so the hook was inside a coffee can, which made it difficult for me to let myself out of the pen when I was working inside it. After I got it finished, I tested it by going inside, unlocking the latch and letting myself out. The goats watched in fascination. Then I went out, locked the hook, shook it to make sure it was latched — and got less than 3 paces from the gate before a goat nudged me. That's how quick they figured out how to unlock it! So if all else fails, use a chain and padlock!"

---

**Curing a Fence Tester:** If a young goat starts going through (or over) fences, Mike finds a forked tree branch shaped like a "Y." The goat's neck goes into the "V" and the ends of the stick are tied above its neck with leather or something. It can't squeeze through fence holes anymore, and jumping isn't convenient either. If a goat grows up thinking it can't do those things, it will give up trying. After 6 weeks you can take off the yoke and there won't be a problem again. If the goat does jump again, just put the yoke back on as a reminder. That's how to raise goats that don't test your fences.

**Picking a Goat:** If a goat knows it can and wants to, it can jump over a 5-foot, or even a 6-foot fence. If I get a goat that has a bad jumping habit, I sell it to somebody who has the kind of situation where they have to picket a goat anyway. To picket the goat put on a collar or halter and attach a light-link chain. The chain is attached to a metal stake that you can drive into the ground with a mallet where you want her to browse. Or use a "stay." That's an old tire or a heavy piece of iron instead of a stake. You can move the stay around occasionally without the trouble of pounding in the stake. None of my goats have to be picketed because we have plenty of room here.

**Catching a Goat:** How do you deal with a goat that jumped the fence and is happily eating your neighbors roses and doesn't want to be caught?
1. Try the grain-shaken-in-a-can bit. Turn the grain so he can see it.
2. If he's leery, walk past him carrying the grain but completely ignoring him. Go pick up some curious object beyond him and examine it. Then put down the object and walk back past the goat, still carrying the grain, and still carefully ignoring it. Whistle if you can. The goat will be overcome with curiosity and follow you. Slow down. At a point of closest approach dive for legs or horns, whichever you think you have the better chance of grabbing. I love horned goats because in desperation I can usually catch them by those handles. Then yell for help.
3. If that didn't work, rope him, and put him up for sale.
4. If you can't rope him, shoot him and make goat sausage.

**GOAT SHELTER:** Goats don't need fancy quarters. Just a good dry place to get in out of the rain or snow. An indoor home with an open door to pasture is perfect. Goats or cows both have plenty of sense to know when to go in and are happiest choosing that for themselves. But Dynah Geissal, who lives in Montana, pointed out 2 important exceptions: "... kidding and extreme cold. Goats can tolerate very cold weather if their shelter is dry and draft free. When the temperature drops to around 20 degrees below however, there may be problems. Newborn kids are especially at risk, as are unprotected udders. At this temperature I add extra bedding, close the barn door to maintain as much warmth as possible, leave a light on to encourage movement even at night, and feed extra hay."

**Goat Hutches.** A quick and easy shelter from rain and sun can be made by putting 4 posts in the ground, adding a sheet of tin for roofing, and wrapping some tin around 3 sides. Dynah Geissal wrote me: "There should be deep bedding, which is changed once or twice a year, fresh air but no drafts, and at least 6 x 6 feet per goat. Never allow ammonia to form. One door may be left open without creating a draft. Bedding should be dry at all times. In case you're wondering—no heat. If your barn is heated, your livestock will not be acclimated to the outdoors. Keep them dry and draft free, and they will be fine. You will also need a keyhole feeder for hay and a method for giving them fresh, clean water. A milking platform or stanchion is also required."

Don Fallick: "Goats love to push on anything handy, so I've learned that goat barn walls must be sturdy. To build a goat shelter, I have the wall boards nailed onto the walls from the inside of the barn, not the outside. I frame 2 opposite walls and slide them from the inside, then scab studs to the corners and frame the other 2 walls. Also, since goats in the wild do not live in caves, they'll never be comfortable in a barn that has no windows, and you'll want light to see by when examining kids, or milking. But windows can be a problem, as goats, and especially kids, jump around so much. There is real danger of them breaking the glass unless it is protected with expanded metal mesh, if you can get it, or 2-inch mesh welded wire fence (not woven wire—it's not strong enough)."

**Goat Sheds.** A quick and easy shelter from rain and sun can be made by putting 4 posts in the ground, adding a sheet of tin for roofing, and wrapping some tin around 3 sides. Dynah Geissal wrote me: "There should be deep bedding, which is changed once or twice a year, fresh air but no drafts, and at least 6 x 6 feet per goat. Never allow ammonia to form. One door may be left open without creating a draft. Bedding should be dry at all times. In case you're wondering—no heat. If your barn is heated, your livestock will not be acclimated to the outdoors. Keep them dry and draft free, and they will be fine. You will also need a keyhole feeder for hay and a method for giving them fresh, clean water. A milking platform or stanchion is also required."

Don Fallick: "Goats love to push on anything handy, so I've learned that goat barn walls must be sturdy. To build a goat shelter, I have the wall boards nailed onto the walls from the inside of the barn, not the outside. I frame 2 opposite walls and slide them from the inside, then scab studs to the corners and frame the other 2 walls. Also, since goats in the wild do not live in caves, they'll never be comfortable in a barn that has no windows, and you'll want light to see by when examining kids, or milking. But windows can be a problem, as goats, and especially kids, jump around so much. There is real danger of them breaking the glass unless it is protected with expanded metal mesh, if you can get it, or 2-inch mesh welded wire fence (not woven wire—it's not strong enough)."

**Goat Hutches.** This is ready-made, portable goat-sized housing. You can buy molded plastic huts for kids from the Pet Castle Co.; 915-643-2517; 800-381-1363; PO Box 1059, Brownwood, TX 76801. VIC offers fiberglass hutches, both small and large: 507-498-5577; 800-537-7145; 111 Maple Dr., Spring Grove, MN 55974.

However, Don warns: "It's tempting to make a goat barn no taller than goat height, to conserve materials and heat in winter. This is false economy. You will eventually need to get into the barn to remove composted manure. Goat manure, with a little bedding thrown in, composes into an extremely dry, tough layer of felt-like substance that must be cut before it can be shoveled. If you don't have room to swing a pick or a mattock, you'll wish you did!"

**Sleeping Platforms.** Says Dynah Geissal: "A nice addition is one sleeping platform for each goat. Some use them; some don't, but the ones that do will really appreciate them. Each platform should be 12 inches wide, 2 feet off the ground, and 4 feet long.

**GOAT FOOD AND WATER**

**Water.** Like other animals (and you), your goats need fresh, clean water available all the time. Freely available water helps goats have good health and do their best milk-giving.

**Food.** I've just read a book that said goats could starve on grass. True, but it's not that simple. Goats need some brush in their diet, but they can get along on brush plus grass and a wide variety of weeds (herbs) and/or vegetables just fine. The vegetables can take the place of brush. They don't do as well just on grain and grass—say, oats and hay. They need some veggies, too. Goats can eat grain, stock beets, corn fodder, carrot tops, lettuce, nice second-cutting alfalfa (they don't care for the coarse stuff), melon rinds—anything from the garden. They like brush, rose bushes, and apple branches, so if you have fruit trees, roses, and berry bushes, you'll have to protect them. Chicken layers' mash will kill goats. Grain or alfalfa will bloat them if they aren't used to it. (If you live near somebody's alfalfa field, install especially good fencing.) In fact, any major sudden change of diet can be rough on your goats.

**NOTE:** Some plants are poisonous to goats, such as azaleas, laurel, milkweed, and wild cherry. Ask your extension agent about problem plants in your area.

**WINTERING GOATS.** I know that in a pinch you can winter goats purely on hay because I've done it. But to keep milk production up and to keep them happiest they need some vegetables, a grain ration, and access to brush. Just what quantity it takes to winter goats depends on the quality of your feed and the method you use to feed. A good winter ration in an average winter around here—which is not a real rough winter—is 6—9 bales of good hay (second-cutting alfalfa) for the whole winter. You ration it out to them —plus a handful of chopped grain apiece per day. They like squash, mangel beets, and carrots, too. That's a good liberal diet for a milking doe. Goats that aren't being milked don't need any grain at all.

**Feeding System.** Feeding in a manger does go farther than throwing feed on the ground. Dynah says a "keyhole feeder" is best of all. And have your hay stored so they can't get in and walk around on top of it because they've no judgment, and will get it in such foul condition that they won't want to eat it.

**Goat-Feeding Myths.** I read recently in a very popular book that goats are "wasteful" eaters. That same book instructed its readers to give them what seemed to me an amazing quantity of grain per day. Well, if you gave any goat that much grain, of course it would "waste it," because they can't eat that much. It also described goats as "finicky" eaters. They can be. Goats are a lot like cats and dogs.
Everyone has heard of Aunt Minnie’s tiger tomat that won’t touch anything but chopped liver and she has to buy it fresh every day for him—or some such. You can do that to a goat if you work at it.

But not everybody has a large range area with a large variety of plants, which is the way goats would naturally meet all their nutritional needs. Consider Dynah’s feed-store-based system.

Dynah’s System. Dynah Geissal has published “20 or 30 articles” on food-growing subjects. I am so grateful she shared her experience in this goat section. This longtime goat-keeper recommends: “Obtain some top-quality alfalfa, 3-way, a mineral salt block, a dairy mineral mix (and a box in which to feed it).

“Her main feed should be top-quality alfalfa—second or third cutting. Feed her free choice in a keyhole feeder. Don’t continuously feed more than she will eat or she will pick out the tastiest bits and leave the rest. A goat is fastidious and will waste any feed that is soiled, and a keyhole feeder will minimize waste. Grain should be fed 1 lb. for each 3 lb. milk produced. Three-way is a good feed for goats and may be mixed half and half with ground barley. Top off the grain with 2 T. apple cider vinegar for each goat. This will aid in preventing mastitis and in keeping down the parasite problem. In the spring, introduce fresh pasture gradually. Feed plenty of hay first and only leave the goats on pasture for a short time. Never turn them out for their first spring grass onto wet or frozen pasture, for this may lead to bloat.

“In addition, provide . . . a mineral salt block and . . . a good dairy mineral mix. It will probably have salt in it; if not, mix it half and half with salt. If your area is deficient in selenium, it should be provided here. Put this mineral mix in a feeder high enough off the floor that it isn’t easily soiled. And . . . provide a natural cattle block. This is a protein mineral supplement. Be sure it has no urea. Urea is poisonous to goats and should never be fed to them. This block should contain molasses, which is good for them any time but is necessary during the winter and 2 months before kidding. They will eat whatever they need of these additives. If they have not been provided previously, they may devour them at an incredible rate at first. After they have obtained what they need, this will drastically decrease.”

Goat Reproduction

Goat Facts of Life: Goats are in their prime generally from 3 to 6 years of age. It is best to breed young does from 15 to 18 months, or at least 10 months old. Too early breeding will stunt growth and heighten risk for dead babies and poor milk production. The usual number of kids for a mature doe is 2—or 1—even 3 or 4. Keep records on your does. They will tend to repeat themselves.

Goats in Heat: Young goats may vary about when they come into heat the first time—breeding them for the first time at about 10 months is ideal. Older ones that birthed in the spring won’t come into season again until fall. In that case, the first chill frosts of September will bring it on. Don’t bother looking for heat signs in summer unless the goat went through the fall and winter without a chance to conceive. Goats come into heat from September to January for 1, 2, or 3 days. So, you have to notice them fast and get them bred fast. The period between heats is 17–21 days.

October and November are the months she’s most likely to conceive. Dynah Geissal: “Some does come into heat in August. You may want to let your buck run with the does early in the season to allow any early breeding to take place. Winter milk is usually scarce.”

Detecting Heat. You can tell when a nanny is in heat because she bleats all day long, runs up and down the fence looking longingly out, and wiggles her tail provocatively and constantly. She is spotting blood if you look closely, and the labia of the vagina are swelled up and red. Dynah Geissal: “Rub a rag on the most fragrant buck available and store it in a lidded jar. In October, display the rag to your doe each day. When she comes in heat, you’ll know! Keep track of each heat so you’ll know her cycle. Then plan for her breeding. After breeding, watch for her heat to be present or absent so you’ll know if she’s bred. A doeling may be bred at 7 months if she is well grown, approximately 70 lb.”

The Buck: You can keep a buck of your own, or maybe take your nan to someone who has one when she needs him. Or artificially inseminate. Twenty-five years ago artificial insemination for goats ranged from uncommon to unheard of. Now it’s a third good option. Goat breeds are basically the same size except for the pygmies. You can breed a goat of any breed to a goat of any other breed, and the results will be goat and will get born fine (that isn’t always true of cow breeds, which vary greatly in size).

Keeping Your Own Buck. The buck is always ready. All you have to do is put them together and he does the rest. A half hour should do it. Bucks are unpopular inside city limits and in crowded neighborhoods because a mature buck goat has a tremendously strong odor. Every time you handle him you’ll walk away with a tremendously strong odor, too. If they aren’t always handled carefully and gently, they can develop some very bad butting habits. If horned, they can be quite dangerous to small children, because a point of one of those horns could come up and get an eye. I rescued my 2-year-old from being butted against the chicken house wall after a friend played at “wrestling” with our buck and awakened his butting instinct. I had to get rid of that buck. Unfortunately, no matter how careful you are, sooner or later bucks will get that butting instinct awakened.

To get your own buck, you can buy a young one fairly cheaply in the spring. He’ll be able to do the job by fall breeding time. Some folks keep the billy goat in a special little house—but I let mine run with the herd. That way I don’t have to worry about trying to tell when the nannies are ready for him.

Dynah Geissal wrote: “Once a year the services of a buck will be needed. Keep a buck, [artificially inseminate], or take your does elsewhere. With 1 or 2 does, a buck would be superfluous; but with a larger herd, a buck would be a significant part of the natural order of herd life. Whether you are buying your own buck or renting the services of one, find out his reliability as a stud and the milking and mothering history of his mother. If possible, obtain a purebred buck, and one that the owner assures you is easy to handle. Inexperienced people should consider a hornless buck.

“The best bet may be to raise your own. In this case, breed the best doe (preferably purebred) to the best buck obtainable. Hopefully, she will produce at least one buckling who will be left with his mother. You don’t want him
thinking that you are mother. Start working with him as soon as possible, but don't make a pet out of him. It could be dangerous if he thinks you are part of the herd. Be firm, even more so than with your does. Put up with no rough-housing, and always let him know that you are boss. Never allow him to get away with challenging you. Teach him early to lead and stand quietly for grooming, shots, hoof trimming, etc.

“Your buck may be used to breed a limited number of does at seven months. He should be separated from the does during breeding season. Otherwise the does will be bred indiscriminately. I once left a 3-month-old buckling with the herd because he was quite small; but surmounting a great difference in height, he managed to breed the entire herd, producing fourteen kids who looked amazingly like him and quite tiny.

“I have never had trouble with the smell of the buck getting into the milk, but it will if the does and buck are closely confined. With plenty of space and fresh air, it shouldn’t be a problem. I wouldn’t want to separate the buck for most of his life, for he’s an important member of the herd.”

Rent-a-Buck. If you can tell when your doe is wanting the buck you can take her and bring her back the same day with fair confidence of success. But it may be expensive. If too pricey, that’s a good reason to keep your own buck, or check into the availability and price of artificial insemination.

Artificial Insemination. Artificial insemination for goats was uncommon or even unheard of 25 years ago. Now it’s a third good option. Ask your county extension agent or local goat folks about local bucks. Or ask Buck Bank about semen, breeding supplies, collection, and training. They offer your choice of champion Alpine, LaMancha, Nubian, Oberhasli, Angora, Boer, Cashmere, Nigerian Dwarf, and Saanen bucks: 541-826-2729; fax 541-826-9717; 2344 Butte Falls Hwy, Eagle Point, OR 97524; dheaney@jeffnet.org. Or contact Wayne and Carol Rhoten; Magnum Semen Works: 301-374-2927; 2200 Alben Hill Rd., Hampstead, MD 21074. To read up on the subject check out Artificial Insemination and Genetic Improvement of Dairy Goats by Dr. Harry A. Herman; or Artificial Insemination Handbook by Vaughn Solomon and Donna Forsman.

Gestation: The gestation period ranges from 146 to 152 days (about 5 months). So wait 5 months minus one day, and then watch for her to spring. Dynah Geissal: “If she has little milk, stop milking when she has 2 months left until kidding. If she has a lot of milk, feed her well (not to fatness), and keep milking her. I’ve had goats who milk well for 3 continuous years with no problem, but they need top quality feed. If she isn’t milking, don’t give any grain the last 2 months before kidding, for a fat goat may have birthing problems. Give shots, worm, and trim hooves 6 to 8 weeks before kidding.”

Ketosis. Stress, overfeeding, underfeeding, and lack of exercise can all be contributors to this pregnancy-related illness. Dynah: “Symptoms are dullness, disinterest in feed, pressing head against something, teeth grinding, and aimless walking. To prevent ketosis, provide blackstrap molasses during the last 2 months of pregnancy. Detection is by using Ketostix to see if her blood sugar is low. The cure is to feed glycerin, exercise her, and keep her eating.”

Kidding: We had a white Saanen buck goat named Miracle. His mother’s name was Mary. He was the first goat born on our farm. He was Mary’s first baby and neither she nor I had gotten into the farm kidding routine yet. She gave birth to him on a miserable rainy day in late February on the manure pile. Mike and I had been through a birth rather recently ourselves when he was with me in the delivery room, and I cried with the wonder of it when he and I found them, and that’s why I named the kid “Miracle.” There isn’t that much difference in the basics. The miracle of life is the same whether it begins among sterile sheets and bad-tempered nurses or in the rain on a manure pile.

And I always cry with joy when it’s over, whether it’s a goat, cow, or me.

Signs of Near Birthing. When the lips of the vulva swell up and the opening becomes longer and larger and the nanny is springing, delivery is near but not imminent. When hollows appear under the tail above and to the left and right of her vagina, delivery will take place within 2 hours. Dynah Geissal: “Kidding may occur as many as 5 days before or after the doe’s due date (5 months, 1 day after breeding). Signs of an imminent birth are a full udder and a thin, clear mucous discharge. This is different from the thick yellow mucous pus which may appear as much as a month before kidding.”

The Kidding Place. When you know a free-running goat is near kidding, check on her every morning. If she doesn’t show up, go find her. If your goats run free in the open, you need to discover the mother with her kids as soon after kidding as possible. Goats, in my experience, aren’t super picky where they have their kids. If she kids in cold weather out in the open, the kids will die if you don’t help them. And we have lost newborn kids to predators. So I would advise that, especially if you live near the woods, keep a goat about to kid near the buildings or in a protective custody until she has kidded and her kids are able to run as fast as the rest of the herd. (Kids develop jumping and running abilities very quickly.) Predators are less likely to come in where the human smell is heavy.

Provide a sheltered place—inside a shed or barn. Cover the floor of her shelter with dry bedding such as straw, hay, or sawdust. Dynah Geissal adds: “A lead goat will choose an appropriate place to kid, but a lower one may not because of being harassed. So be sure to isolate her in shelter before kidding. When it’s been determined that your goat will be kidding within a few hours, isolate her in a place that is familiar to her. Be sure that it’s dry, draft-free, and has plenty of bedding. Provide fresh, clear water in a small bucket (to minimize the chance that she will drop her kid into the water). Give her plenty of good hay.”

The Birthing. Kids are usually born in the early morning hours. The mother probably won’t need any help from you with the birthing itself. But if she does, here’s Dynah Geissal’s expert instructions on what to do:

“Generally speaking, a goat should be left alone to kid. If she is very attached to you, she may be reassured by your presence. Most goats, however, prefer to be alone, although they do seem to be more at ease if they are able to see their herd sisters. Be sure to check on her frequently during her labor. It may be many hours before hard contractions start. If she seems at ease and eats or chews her cud, all is well. When hard labor begins, your doe may lie down, pant, and call out during a contraction. Between contractions, she will get up and resume cud chewing in the early stages. This may last several hours.”
“When the kid is showing, check to see which part is presenting. If the front feet are first, with the head resting on them, everything should proceed normally. This stage may last as long as an hour. Unless things proceed rapidly, clean the kid’s nose and mouth before it is born.”

**Assisting in Kidding.** Dynah, again: “There are certain circumstances where you will have to aid in the birth or get someone else to help you: ... If the water breaks and more than 2 hours have elapsed and there is no kid in sight, your goat probably needs help. ... If she seems to be in great pain, wait no more than half an hour before assisting her.... If she seems exhausted, wait only a few more minutes—maybe fifteen.

“If the kid is presenting, you may have to do no more than pull gently downward with each contraction. This is sometimes necessary with an especially large kid. When the kid is presenting, but in an abnormal position, you will have to enter the vagina. Scrub your hands and arms thoroughly, paying special attention to your nails. Oil your hands and arms. A presentation that is normal except that the head is turned back is easy to correct, but almost impossible to give birth to if not corrected. The same is true if one or both feet are tucked underneath the kid. A kid that is presenting normally but upside down may be turned. A breech birth may proceed successfully if the feet come first; but there must be no delay once it is presenting. The cord may be constricted in the birth canal. When the kid is coming rump first, it may be born with some help from you during contractions if it is fairly small. Otherwise, you will have to push it back and bring out the feet first.

“If the kid is not showing, but you have decided that your doe definitely needs help, reach in very carefully to prevent rupturing the vagina. In a situation where you cannot feel the kid, the cervix may not be open. In this case, you should consult a vet. Assuming you can feel the kid, determine its position and reposition if necessary. This is probably all that is necessary. On the other hand, when her water has been broken for a long time or if she is exhausted, or if the kid is very large, you may have to also pull the kid during contractions.

“A goat who has serious birthing problems 2 successive years should be butchered. I once had a goat who seemed to be giving birth normally: 2 feet were out but then nothing. When I began to examine her, I found that one leg was much larger than the other; 2 kids were trying to be born at once! I had to push one back to free the first. Then the process repeated itself, and 3 healthy kids were born.”

Sue Bradford, Kansas, IL, wrote me: “My best milker, Storm, almost died giving birth. I knew she was in trouble. Phoned my boss, explained, and was told, ‘She’s only a 2-dollar goat and you’re going to lose a day’s pay!’ She’s a pure bred Nubian, but that doesn’t matter. She was in pain and any animal in my care will not be left to die. Anyway, this was my first experience delivering. She had delivered a kid hours before. I found she had the next kid sideways. I got him out and of course he was dead, but then out popped a beautiful little girl kid! I gave Storm a pail of warm water with blackstrap molasses to drink. She drank it all, but wouldn’t stand up. She wouldn’t even look at her kids and wouldn’t stand up. I still don’t know how I did it, but I lifted her up enough to get enough milk to get both kids started on the bottle. It was a few days before Storm could stand without help, so I held her up every day while my husband milked her. Her next kids were born without problems. I love this life! I was raised in town, but my husband, Lee, and I have lived on his family farm (90+ acres) for 26 years now. We now have a ½ acre garden, fruit trees, goats for milk and meat, and chickens for eggs and meat. I’ve learned to sew, make quilts, can and freeze garden get, make jelly, milk goats, make cheese. I even cut up a deer and goat and made salami.”

**Does’ Post-Birth Feeding.** Dynah Geissal recommends: “Feed mother 1 lb. grain plus warm water containing molasses.” That drink of warm water with some molasses in it is a real help to a goat that is kidding. She may drink as much as a gallon. If she seems chilled and seems to be having difficulty expelling the afterbirth, the drink of warm water also helps.

**Afterbirth.** The afterbirth comes out after the kid. It may take a long time to finish coming out. Leave it alone. I know how miserable it is when the doctor gets in a rush about afterbirth. It will come out in time. You put her more at risk by pulling on it, because that may make her bleed! When she gets done passing the afterbirth naturally, she may or may not eat it. If she does, it’s recycling. If she doesn’t—well, after all she’s not a meat eater by nature.

**Care of the Newborn Kid:** Carry a towel with you and dry the newborn as soon after birth as possible (getting born is a wet business). There is no reason for you to tie the cord. My advice would be, in fact, don’t. Leave that part of it up to nature. I usually don’t find the babies until after nature has taken care of that part anyway.

Dynah Geissal’s system: “Have dry, clean towels ready and either iodine or alcohol. When the kids are born, clean the faces immediately. Let mother take over, but if she doesn’t do a good job, you should. Dip the cord into an iodine solution as soon as possible (don’t dab it on). The cord is a wick to bacteria and infection. ‘Navel ill’ is an infection of the umbilical cord which spreads to the kid’s entire body, especially the joints. It is prevented by dipping the cord in iodine or alcohol immediately after birth. It is treated by antibiotics or sulfa.”

**Helping Kid Nurse.** Dynah: “There are usually 2 kids born and 3 is not unusual. The kids should be up almost immediately. Be sure the kids receive colostrum right away—hopefully within 15 minutes of birth. If not, help them up at least to nurse. If the kids have a strong sucking response, hold the teat and the kid until its initial hunger is satisfied. When the sucking response is weak, get some milk into the kid and then try in a couple hours. If a kid is not nursing on its own, you’ll have to help. If the kids are weak, or there are multiple kids, you may have to help for as many as 3 days. You will learn quickly how often they are hungry—usually every 3 to 4 hours. Once you are certain that a kid has nursed on its own, it won’t need your help any more.

“If there is no sucking after several hours, you will have to bottle feed the kid, if you want it. Once is usually enough to get it strong enough to nurse. Give the bottle as few times as possible so the kids learn to nurse the mother rather than depending on the bottle. Don’t keep the kid in the house or its mother may reject it and it won’t have adapted to the temperature of the barn. If the kids are bottle fed, they tend to become pets. You’re their mom and, personally, I don’t think livestock should be pets. I have
dogs and cats for that. A pet goat is usually intractable and as obnoxious as an untrained dog. My goats are friendly and affectionate, but they are members of the herd, not the family."

Chilled Kid. If a goat kids outdoors in cold weather and the kid seems to be inactive, it's probably chilled. You may even find a kid that's weak, or prostrate from the cold. Just pick up that little baby in your arms and carry it into the warmest room of your house. Keep it wrapped in warm cloth and put it in a cardboard box near the heat source until it dries off and gets warm and is thoroughly recovered. When the kid climbs out of the box and wobbles all over the house nuzzling at everybody optimistically, it is doing fine for a 6-hour-old baby. Its little tail will wag and its disposition already demonstrates the incurable curiosity of goat.

Separation of Kid and Mother. One school of thought advocates taking the kid away from the mother immediately so she won't get attached to it and be harder to milk later. Another is to leave the kid with the mother for 3 days and then separate them. But since the latest research has shown that animals nursed by another animal are more respectful of humans and much safer to have around when mature, owners are trying harder to find a way to keep the kid on the goat. You can't change your mind in the middle because, if the kid is taken away from its mother for the first 6 hours or more, on its return she may well butt it viciously and refuse to mother it. Here's Dynah's system for leaving the kid nursing its mother:

“Kids should stay isolated with their mother for 3 to 5 days or until they are strong, active, and nursing well on their own. Then turn them out to the herd. The only time I have had a problem with this is when a yearling calf crushed 2 kids behind a door. So if you have large livestock sharing their barn, keep them separated a few extra days.

“Check the mother's udder twice a day to be sure it isn't too full. She will probably need milking after 3 days, but if not, you could wait up to 5 days. Except for the grain milked or handled her much before, you'll find birthing has made her completely gentle and she'll cooperate fine with you. Save that colostrum milk to feed her baby if you will be bottle-feeding. Take the milk to the house, put some into a small pop bottle, using a lamb nipple on the end of it, and feed it to the baby. Just get the nipple in its mouth and it'll get the idea. Never feed cold milk. After a few feedings and a really good warming the baby goat will be fine and can go back out to the barn to live. Or if it still seems to be doing poorly, you could keep it in the house until you feel sure it's strong. If the kid is too weak even to nurse the long, soft lamb nipple, you can feed it with an infant syringe (the rubber bulb you use to clean a newborn baby's nose), available at drugstores or a spoon.

Don't use a human baby bottle. It's the wrong style nipple. You should have several "lamb" nipples on hand (baby lambs are treated exactly the same way) well before the birthing. It's terribly important to get that first good nourishment into a chilled newborn animal. You'll be amazed at the change. I've found kid goats that looked almost dead. But after they were warmed up and had a meal in their tummy, they stood up, bleated, and wagged their tails. After 2 hours and another meal they were just fine.

Lamb nipples don't have an internal air supply like baby bottles that feed air in through the rim. The kid has to learn to let go of the nipple every so often so air can rush in and equalize the pressure; otherwise the milk will stop coming.

Timing the Feedings. Feed every 2 hours the first day, 4 hours the second day, 8 hours the third day, then morning, noon and night for about 10 days, and from then on morning and night after you milk. Notice how much they are eating and finally get over it, but sometimes it kills them. Goat kids have a hard time on any milk but their natural milk. That powdered stuff is the worst thing I know of; powdered milk is next; and cow's milk is best for them. (Bigger kids can handle cow's milk better than little ones.) If a goat kid on anything but goat's milk is scouring, then a half bottle, a bottle, or all goat's milk for several feedings will usually clear it up. I am always very reluctant to sell

Scours. The turds of goat kids should be round and firm, miniatures of mama's. When goat kids (or calves) get a loose diarrhea; it's called "scours." Chilling and overfeeding are the 2 greatest dangers. Sometimes they scour a while and finally get over it, but sometimes it kills them. Goat kids have a hard time on any milk but their natural milk. That powdered fake stuff is the worst thing I know of; powdered milk is next; and cow's milk is best for them. (Bigger kids can handle cow's milk better than little ones.)
unweaned kids to people who don't have goat's milk to give them because I know they'll have a hard time keeping the kids healthy.

If you are milking goats and have yearlings, or a poor milker, or they all have triplets—you don't have much choice. You're going to have to kill some kids to insure your family milk supply or else find homes for them elsewhere. You can't afford to buy milk for them. They are worth only a few dollars, if you can find somebody to take them. They aren't as important as having milk for your own children. If you try to raise them on that cheap milk substitute they'll be scouring and sick most of the time, and you'll spend whatever you saved on Kapectate and antibiotics trying to help them hang on.

**Surplus Newborn Kids.** I try never to kill a nan kid because it is a waste, but when I have more billy kids than I have extra milk for, and nobody wants them, I kill them. This is hard to talk about and hard to do, but I'm going to tell you how because I'm writing this book for people trying to do real things in difficult situations, and sometime you may need to know this. Dynah Geissal says on this subject: "Before your kids are born, decide how many doelings you will keep and stick with it."

If I'm going to kill the kid I get there as soon as possible. I check for sex. Then I take the little billy out of earshot of the mother and hit it as hard as I can on the head with a hammer. That blow probably suffices. The newborns don't have much stamina, but I hit it a couple more times to make sure. Better have it quick, certain, and complete if it has to be done.

**Calf Adoption.** It takes about 2 good goats to support 1 calf. Get your goats milking well first, and then you can acquire the calf. One really good goat can support a calf if she can be persuaded to adopt it and let it nurse her.

**Kids for Meat.** If you do have extra milk, then by all means raise your extra bucklings and cull doelings for meat. If you don't have a market for them, you might as well eat them yourself. Since goats typically have more than 1 kid at a time, and they can even kid twice a year, you have extras pretty fast once you get started. The animals can be butchered when they're big enough to suit you. Even a kid 6 weeks old will add 15 lb. of meat to your supply. But the longer you wait the more meat you'll get—up to a point. Calves keep growing until they are about 2 years old, and the same with goats.

**Sexing Kids.** What you plan for the kid may depend on its sex. Boy kid goats have small testicles hanging from their tummy, just to the front of their hind legs. They pee from the middle of the tummy so it runs straight down as they stand. Girl goats don't have those testicles and they pee from the rear, squatting backwards as they do so.

**Of Big Kids and Weaning.** Incidentally, big babies that are still nursing tug so hard they are liable to pull a rubber nipple off a bottle. You'll have to hold it on the bottle as they suck. A goat can be tapered off when he is eating other feeds well, weaned completely at about 4 months.

**Castrating.** Male kids, like bull calves, are usually castrated for easier management. Dynah says, "Male kids should be castrated by one month of age. I use an elastrator and have never had a problem. Don't wait any longer than a month or it will be too traumatic. I castrate the males so they can run with the herd. If they aren't castrated, they must be separated from the does by four months."

---

**Goat Manners:** Dynah Geissal: "Goats are very smart and can be taught manners. Don't allow your goats to jump on you or to jump up to get feed you're carrying. A slap on the nose and a loud "no" will save a lot of irritation and hassle. Don't allow loose goats to butt or to steal food from a goat who is confined in a stanchion."

**Goat Vetting and Grooming**

See the general section in Chapter 8, "Introduction to Animals." Dynah Geissal: "Disease is not usually a problem with goats if they are fed top-quality feed and additives, get their shots on time and are well maintained."

**Toenails:** Some goats never seem to have toenail problems. Others have toenails that grow and grow, and you have to cut them off to keep the goats from becoming virtual cripples trying to get around with all that nail on each hoof. A young goat has fairly soft hooves and you can trim them with a knife. Make them look like a newborn's hooves, but don't go far enough back to get into the quick. Though it may make them nervous, it doesn't hurt. On an old goat the hooves are very hard, and you'll need a meat saw or regular hoof nippers to do the job. I bought an old doe once who had 5 inches of toenail that had to be sawed off from the front of each hoof. The best way to keep up with it is to trim once a month. But don't trim hooves right before or right after kidding.

**Parasites:** Dynah Geissal says, "If other goats come to your farm, assume they have parasites and act accordingly. Never loan out your buck, but have the does brought to him."

**Worming.** Dynah, again: "Worming should be done 3 times a year. The whole herd should be done together (within a few days of each other) at least one of those times. Does should be wormed 6 to 8 weeks before kidding. Other times could be before confining for the winter, before turning out in the spring, before breeding, etc. I use TBZ, which can be used during pregnancy and during lactation."

**Lice.** Dynah: "You will probably need to dust for lice each year in the spring. Choose a dust that is safe to use on lactating dairy animals and poultry. These are the safest as well as effective. Dust immediately after the morning milking and do it outside. Kids under 8 weeks should be dusted with ashes."

**Shots:** Dynah: "The best time to inoculate goats who have been confined for the winter is just before turning them out and no closer than 6 to 8 weeks before kidding. Don't forget your buck. If red water is a problem in your area, you will need to give 8-way. Ask neighboring ranchers or your local extension service. If they vaccinate their cattle for red water, so should you vaccinate your goats. If not, use 7-way."

**Horns:** Dynah: "Horned goats will tend to scatter, then stand and face the predator. Hornless will just run, which encourages chasing and may lead to injury or death." For dehorning see Chapter 8.

**Bleating:** Some goats are very noisy. If your choice is to have a silent goat or no goat at all, get a goat, and if the bleating becomes a problem you can have it debleated at the vet's. Keeping the kids and mama out of sight of one another and separating them before they have a chance to get really attached helps. A nan in season will be noisy, and actually that's a convenience because it lets you know when she is ready to be with the billy. To me, debleating is a last
Dealing with the head glands doesn't solve the problem entirely; there are also leg glands that produce scent.

Goat Butchering

We've eaten a lot of goats. Goat meat is "wild" flavored, resembling venison in taste. I've made goat stew, goat steaks, and goat burger. I prepare those all pretty much on the same basic plan as other meats. If serving goat meat to a guest who isn't used to the taste, I might camouflage it in a wild meat recipe. We never have cut roasts off our goats. I'd rather serve and eat the meat fried, or in burger, or made into sausage, so it's always either sliced or ground. Goats are easy to butcher and cut up. If you've ever done a deer, it's the same thing. Goat meat is technically called "chevon"—and in the Southwest market, "cabrito" or "cabra" means young goat, just like pig meat is "pork" and cow meat is "beef."

Of Goat Age and Butchering: You butcher a kid goat the same way you do an adult, basically—only the whole thing is quicker because there is less of everything. If you need milk more than meat, it makes sense to butcher kids at birth. Use the rabbit butchering directions for that size. Most people don't butcher before 12 weeks of age because you don't get much meat. There is quite an Easter/Passover market for milk-fed kids that are about 20 to 30 lb. To maximize their meat production from a buck kid, however, most homesteaders butcher surplus kids at 5 to 9 months old. That way you have an animal big enough to make small steaks and even small roasts.

After the kid is skinned and gutted you can roast it whole on a spit, barbecued, like for the Fourth of July when you have lots of guests. Or you can quarter it for barbecuing or roasting, a quarter at a time for a regular meal. The other age at which goats are most frequently butchered is "old"—mostly cull does. These are nans that can't be bred, or don't give enough milk to bother, or can't be milked or can't be controlled. Older goats are generally boned and the meat ground for goat burger or sausage, appropriate uses for strong-tasting, nontender meats.

Cutting Up: To cut up a goat, follow the directions given in Chapter 8 for cutting up a deer. You have to use your own judgment and cut your meat according to the size of the animal and the use you need of it. How you cut it up also depends on whether you have power meat-cutting equipment available. If you have a band saw, cutting meat is so easy that mini-steaks (the kind you'd offer about 3 to a serving) are fine. But if you have to saw out each one the hard way (sawing through the bone by hand), there is scarcely enough meat on them to make it worth the trouble.

Goat Recipes: Use any recipe from the wild mammals section in Chapter 8, especially if it's suggested for deer. Goat meat is so much like that of deer, antelope, moose, elk, etc. Or get Chevon Recipes from Caprine Supply, for more than 70 good goat-meat recipes. And get the Dairy Goat Cook Book by C.A. V. Barker, available from Dairy Goat Journal.
The main source of power. They pull the plow and furnish beef and dairy breeds: (1) Gentleness: Beef-breed cows are the water-buffalo-type animal most common in Asia. In the most heavily populated parts of the world, cattle are the not usually to be milked by ordinary mortals. Angus, for example, are very excitable animals. You'd never be able to catch one to milk her. If you want to milk a cow, you want one that is born with dairy-cow genes. (Yet somebody somewhere has made a milk cow at some time out of every beef breed there is.) (2) Milk production: The main difference between beef and dairy breeds, besides gentleness for milking, is milk production. A good beef cow has enough milk to raise 1 healthy calf without a grain supplement. A dairy cow can easily raise 2 or 3 fine calves (which you can generally persuade her to adopt by shutting them up in the barn together for a while), with a grain supplement. (3) Difference in build: "conformation." The dairy cow is lean, bony, has less muscle in places that would make high-priced steaks and roasts. When you buy a dairy-type animal you're buying a greater percentage of bone, but the lower price will compensate for it.

**Dual-Purpose Breeds.** A "dual-purpose" breed has a beef conformation with a dairy-type ability to produce milk. The Shorthorn is a large cow in this category—the "milking shorthorn" more so than the "beef shorthorn." The Brown Swiss is another beef–dairy combination cow. The river buffalo is a triple-purpose breed: milk, beef, and draft!

**Dairy Cattle**

Cows, at their best, are really multipurpose animals. They make meat and manure as well as milk. From the beef point of view, milk and all its wonderful by-products like yogurt, cheese, butter, and ice cream, are just an extra added bonus. And then you can also use the extra milk to raise more meat and eggs by feeding it to the pigs, baby calves, and chickens. I think the most efficient way to get your beef is to have a milk cow and use the extra milk to raise a couple calves a year. You'll get them cheapest if you buy them at 1 day old.

**Dairy Cow Information:** Check out Joann Grohman's *Keeping a Family Cow* (1984); Phyllis Hobson's *Raising a Calf for Beef* (1976) (good up to 6 weeks old); and Dirk van Loon's *The Family Cow* (1975). For a periodical, if you're interested in commercial milk-production from cows, subscribe to *Hoard's Dairyman*, 920-563-5551; fax 920-563-7298; PO Box 801, Fort Atkinson, WI 53538-0801; [www.hoards.com](http://www.hoards.com). Hoard's also offers dairy books such as *Calf Care, About Cows*, and *Dairy-Related Careers*. A word of caution: There is a lot of baloney in cow/calf books written for the family farm. Even certain ones I've recommended here have some really stupid misinformation mixed in with the good information.

**Dairy Cow Age:** A cow can bear calves annually and be milked until she is 10, 12, 14, even older. The old-timers sometimes kept one going to age 20. But, sooner or later, you'll find it impossible to get her bred again. So a 4-year-old cow is a fine buy.

"Heifer" used to mean a female cow that had not yet had a calf; now some folks use the term to mean a female cow that hasn't calved a second time. Heifers sell cheaper, but they may be unaccustomed to the calving and milking routine—which could be a problem if you are too. They may have trouble calving if it's their first time, and cows, like goats, give only half as much milk the first year they are fresh as they will later on. One way to avoid this calving difficulty is to breed the heifer with a bull of a small dairy breed, like a Jersey, or with a bull of a small beef breed, like a Black Angus, which are deliberately selected for small calves—hence easy calvings.

**Dairy Breeds:** Jerseys and Shorthorns have the reputa-
Questions to Ask When Buying a Family Milk Cow

You could watch the ads or advertise for a “family milk cow.” Don’t buy a milk cow at a livestock auction if you can help it.

1. What breed is she?
2. How old is she? One option—cheapest to get started, longest to wait—is to buy a calf, or a heifer, and raise her to be your milk cow.
3. How many seasons has she been milked? For a milk cow, a bred heifer would probably be most affordable, but a 3–5-year-old cow in her second to fourth year of milking has experience calving and being milked.
4. Has she ever been hand-milked or is she accustomed to machine-milking? Not a problem, you can teach her. But it will help to know.
5. Watch her being milked if possible. Examine her milk for signs of mastitis, such as stringy milk, clots, blood.
6. Is there proof the cow doesn’t have tuberculosis and is immunized against brucellosis?
7. How many calves did she have? Twins? Cows usually have single births, but if she’s had a double you will be forewarned next calving.
8. Any delivery complications? Once a problem raises the odds of having a problem again.
9. Is she fresh (milking) now? Or, when will she come fresh (give birth)?
10. How long has she been fresh (milking)?
11. How much money do you want for her?
12. How many gallons of milk does she give per day? (Or if not fresh, how much did she give last time she was fresh?)
13. How much of that is cream?
14. Any health problems?
15. Behavior problems? Does she go through fences? Does she self-suck (milk herself)?
16. Is she gentle? (Test that by walking up to her. Put your hands on her udder and legs and see if you get kicked.)
17. How much does she weigh; and see if you get kicked. How much food would it take to get her through a winter?
18. How low does her udder hang? (You want to be able to get a bucket under it rather than just a cake pan.)
19. Does she have nice long teats or would you have to milk with 2 fingers and a thumb? Can you reach all 4 teats from one side of her?
20. Is she pedigreed? If so, get her papers because then you might be able to sell a heifer calf for a little more. But avoid paying a breeding-stock price when what you want is just a family milk cow.

NOTE: Tuberculosis and brucellosis are rare diseases but are worth taking care about because they can infect humans through the milk. Buy animals that are guaranteed free of these (vaccinated as calves for brucellosis and tested free of tuberculosis). Or get them tested yourself before drinking any milk.

NOTE: If you buy a cow that is being separated from her calf for the first time, watch her carefully for the first 12 hours. She is going to be very emotionally upset—enough so as to go wandering all over the country, mooing loudly, if you leave a gate open. Cows are very home-oriented, but she doesn’t know yet that your place is home.

Jersey. The Jersey is a small, dairy-type cow that gives lots of milk with a high butterfat content, the highest of any breed. Jerseys are the smallest breed, half the size of Devons (and so eat half as much). Guernseys are next bigger. Milking Shorthorns, Brown Swiss, and Holsteins are next up in size. Red Poll and Devon cows are also dual-purpose breeds. They are exotics and the biggest I’m going to mention. To a certain extent your cow will be priced by the pound, and that makes the larger breeds more expensive. Rare breeds are likely to be the highest priced of all. Milking Shorthorns and Brown Swiss are among the dual-purpose breeds, stocky builds for meaty calves, plus easy calving and good milk production, which are dairy characteristics. The amount of milk you get from an individual cow is a result of her breed, plus how much and what richness of feed you give her.

Ayrshire. Another fine basic dairy breed. For more info, contact the Ayrshire Breeders’ Association: 614-882-1057; fax 614-895-3757; 267 Broad St., Westerville, OH 43081; info@aurshire.org; www.aurshire.org.

Brown Swiss. A Brown Swiss is large, tan-colored. Brown Swiss may have some calving difficulty on the first calf because they have large calves. Brown Swiss Cattle Breeders’ Association: Box 1038, Beloit, WI 53511; 608-365-4474.

Dexter. The Dexter is a small dual-purpose (meat and milk) breed from Ireland. For more info, contact the Dexter Cattle Association, 404 High St., Prairie Home, MO 65068; 660-841-9502; info@dextercattle.org; www.dextercattle.org.

Guernsey. A Guernsey is yellow and white. Only Jerseys are smaller than Guernseys. The Guernsey has a lower cream percentage to its milk than the Jersey, but more than the Holstein. Guernseys have a reputation for being very docile and manageable, as do Jerseys. Their milk has a slightly yellow tint. American Guernsey Association: 7614 State Ridge Blvd., PO Box 666, Reynoldsburg, OH 43068-0666; 614-864-2409.

Holstein. The Holstein cow is a big, lean, black-and-white animal—a bony, pure-dairy type. It used to be that they gave up to 6 gal. per day, but now that’s up to 10–14. Their milk has the lowest butterfat percentage of any dairy breed. Because of typical Holstein size, there is actually a lot of beef on a Holstein bull or steer. So a Holstein bull calf could actually be a good choice to raise for a beef calf. Holstein owners wisely breed their heifers to Herefords (a small, beef animal) for easy calving, and later, to a larger-breed bull. Almost the only dairy cow being used these days for commercial operations is the Holstein. Holstein Association USA: 1 Holstein Place, Brattleboro, VT 05302-0808; 800-952-5200.

Jersey. The Jersey is a small, dairy-type cow that gives lots of milk with a high butterfat content, the highest of any
breed. They are wonderful family cows. A Jersey gives about 3 or 4 gal., 4 in her prime—which for almost any family would be plenty. The Jersey costs less to keep than larger dairy cattle because she is smaller and eats less, but she gives less milk, and the bull calf (your meat) doesn’t grow as large as most others. Jersey bull calves sell especially cheap because Jersey fat is yellow. On the market this is confused with old bull fat, so feeders won’t touch them. But for homestead use they make fine meat. Jersey and Milking Shorthorn are the 2 most popular in our area for home milk cows. Although Holsteins are the dominant cow in the United States numerically, I’ve heard that worldwide the Jersey is most common. American Jersey Cattle Club: 6486 E. Main St., Reynoldsburg, OH 43608-2362; 614-861-3636; www.USJersey.com.

Water Buffalo. This misunderstood and underestimated Asian bovine has extraordinary potential. It’s large and not particularly good looking, but very gentle. The 2 major types of water buffalo are the swamp buffalo, or carabao, and the river buffalo. Both are good draft animals and good meat producers. The carabao is rarely milked, but the river buffalo is an excellent dairy animal. River buffalo are now being used in Latin America, working in tropical mud that would bog down a tractor. Their working life as a draft animal can be 20 years.

Mozzarella cheese was traditionally made from the milk of river buffalo. River buffalo milk has more butterfat (7–9 percent) and more nonfat solids (18 percent) than cow’s milk. River buffalo are the basic milk producers (70 percent) for India, Eastern Europe, and many Middle Eastern countries. Both river buffalo and carabao produce meat that is leaner than beef (50 percent cholesterol), and just as tender. They do better in hot weather than cattle, but still need access to shade or a pond.

Shorthorn. Milking Shorthorns can be fine dairy animals too. But pure white Shorthorn heifers sometimes have an inherited defect that prevents them from conceiving. And in our experience they were somewhat more disease-prone than the average, especially to pinkeye. Shorthorns give plenty of cream. Their butter is white, rather than yellow. American Milking Shorthorn Society: 608-365-3332.

Crosses. Gardening and food writer Lane Morgan, who reviewed the manuscript of this book, says their milk cow is a Holstein–Hereford cross and a very good family cow! You just have to decide what is best for you.

### Beef Cattle

For raising these animals practicality has to be the bottom line. A beef cow has to raise a calf each year or . . . become hamburger. You can’t afford to keep beef cattle if it costs you more to raise their only product, the meat calf, than what you can sell it for. Expenses come from feed, medicine, and vet visits, fencing, and the cost of the grassland you pasture them on. As with any business, you have to keep production up and costs down. Rotation grazing on a good pasture works well.

#### Beef Cows in Print:

#### Beef Breeds

**Angus.** If you’re worried about pinkeye, get the Black Angus breed. They’re as good at foraging as Herefords, plus very disease-resistant. Angus are as wild as the proverbial March Hare, so they don’t make family milk cows. They’re not big, so there isn’t as much meat per animal. And their small build causes calving problems; you’ll have to get good at recognizing and helping with calving problems.

**Beefalo.** This is a buffalo-cattle cross with, some feel, the best of both breeds.

**Buffalo.** This close relative of cattle is a low-cholesterol, low-fat, high-profit meat animal (producers can get $18 a pound for buffalo tenderloin, $28 a pound for jerky). If there are plenty of boys and girls, food, and water, and you’re lucky, they may stay inside your fencing. They can be fed a grain and hay diet just like a feedlot cow and be kept under similar circumstances. One lady keeps 9 buffalo on 10 acres. Eighty percent of this country’s buffalo are now privately owned (Ted Turner and Jane Fonda have the biggest buffalo ranch: more than 5,000 head). However, these animals can be hard to control.

**Exotics.** Charolais, Limousin, Simmental, and a whole list of new breeds called the “exotics” are simply huge beef animals. Charolais cows tend to have trouble with their first calves because their calves are so big. A farmer nearby who raises them loses about 1 calf in 5 born to his Charolais heifers.

**Hereford.** The famous red-and-white Hereford cows are small like Angus, with a terrific foraging ability. Their small-boned structure is comparatively efficient at food conversion. A Shorthorn would starve to death on the deserts of southern Idaho and Wyoming, where Herefords can wander and grow fat. But, as with Angus, the smallness also brings less meat and more calving problems. A breed of miniature Herefords is now also available: (08) 8388-8393; info@oradala.com; www.mini-hereford.com.

Miniature cattle breeders have a society and registry. They provide info on all 24 breeds of these mini-cows and also publish a newsletter: *International Miniature Cattle Breeders Newsletter* (6 issues, $25); 253-631-1911; fax
253-631-5774; 25204-156th Ave. SE, Kent, WA 98042; info@minicattle.com; www.minicattle.com. For example, there are Lowlines.

Lowlines: These black miniature cows were created in Australia. A 14-month-old may weigh 314 kg live. Lowlines are docile, polled, with marbled meat: info@oradala.com; (07) 3202-9414; (02) 6226-5222; www.lowlinebeef.com.au.

Longhorns. If you want dramatic (scary) big horns on animals who can look after themselves very well, thank you—get Longhorns.

Scottish Highland. These cows have horns resembling the longhorns, but also coats of long, shaggy hair which makes them very hardy against both weather and predators. Joyce Hetrick gives tours of her operation and sells registered breeding stock, halter-trained and gentle: PO Box 667, Greenbrier, AR 72058; Joyce@Heifercreek.com; www.Heifercreek.com. The American Highland Cattle Association is the national breed association, offering info, a quarterly magazine, and breeder's list: 200 Livestock Exchange Bldg., 4701 Marion St., Denver, CO 80216.

**OXEN: Cattle That Pull**

Any bovine that has been trained to pull is a “draft ox” or “bullock.” If you have 2 or more of these trained cows, you have a “yoke” or “pair” of “oxen.” Technically, a steer calf, yearling steer, 2-year-old, or 3-year-old can be pulling, but it’s not until the animal is practically mature at 4 years that it fully qualifies to be called “ox.”

**DRAFT BREEDS:** Any gentle breed of cow can be trained to pull. Usually people work with steers from a large dairy breed, such as Holstein, because they’re easy to get hold of. The Charolais, a French variety, are very large, powerful animals that were traditionally used as oxen in that country. They aren’t terribly bright but are of a peaceable nature. Best of all are the water buffalo.

**OXEN VS. DRAFT HORSES:** Farmers argued for generations over whether bovines or horses were better as draft animals. Jared von Wagenen, Jr., wrote in The Golden Age of Homespun of “great patient brutes with hooves that grip the earth, mighty shoulders, heaving flanks, and drooping heads, placid eyes, and spreading, gleaming horns—the glorious ox team.” Draft horses are more popular in the United States, to the point where the knowledge of how to train cows for draft work has teetered on the brink of extinction. A wonderful book called Animal Traction by Peter Watson (1981, revised 1983) offers solid information on every aspect of using oxen for cultivation.

**ADVANTAGES OF OXEN FOR DRAFT WORK**

1. Many a pioneer family whose cow pulled their 2-wheeled oxcart or wagon were grateful that she also gave milk and gave birth to calves.
2. Oxen use a far less complex and less expensive, less perishable, harness than horses. They simply have their wooden yoke which is low-cost and easy to make and lasts a lifetime. The yoke gets directly attached to the tongue of the farm implement or wagon, or to a chain that is attached to their load. In the woods, there is no need for whiffletree or trace chains, only the chain going to their yoke. The traditional wooden ox yoke is cheaper than horse harnesses, although the old-timers sometimes harnessed with leather rather than yoked their oxen—and considered them less hard on harnesses than horses!
3. Oxen are generally less likely to jerk and startle than horses, more gentle and docile by nature.
4. A typical ox is heavier than a typical horse, with more pulling power. Von Wagenen wrote, “It was in the rough, hilly sections that oxen were found in the greatest numbers and lingered longest.” But that is hotly disputed; I’ve heard elsewhere, “It takes 2 yoke of cattle to do the work of one 1,200-lb. team of horses.”
5. The pioneers considered oxen to be better among stumps and stones than horses.
6. Oxen can be shod, but aren’t as needy of it as horses. And don’t shoe your oxen until they’re at least 4 years old because before that their hoof isn’t strong enough yet for a nail. And, once shod, an ox holds a shoe longer than a horse. (If oxen are worked a lot, they need shoes. A horse takes a single shoe per foot. An ox requires 2 shoes on each foot, 1 for each half of their cloven hoof. A horse will allow its foot to be picked up and held; an ox usually won’t easily cooperate, but it can be done.)
7. Oxen are claimed by their owners to be healthier than horses. The old-timers believed oxen could do more work on a diet of plain hay and pasture than a horse.
8. The price of a potential draft cow is less than that for a draft horse—bull calves are cheap to get if you have milk cows.
9. Oxen are good in deep snow.
10. An old, or retired ox can be converted to hamburger for the family. Old horses get sold for dog food, but are not eaten at home.
11. Oxen are more patient and less likely to injure themselves. (Horses are faster.)

(For all the good things about draft horses, see The Draft Horse Primer by Maurice Telleen.)

**RESOURCES**

Association of New England Ox Teamsters works to preserve New England traditions: Linda Wilbur, Secretary; 603-357-4197; 989 Old Walpole Rd., Surry, NH 03431; lhwmoo@earthlink.net; home.attbi.com/~cynthial23.

Berry Brook Ox Supply sells ox equipment: new and used yokes, bows, ox shoes, goads, whips, logging equipment, horn knobs, horn weights, yoke hardware, books, videos, etc. Their newly manufactured logging/farming fore cart and logging scoot are of good...
quality and reasonably priced: 603-335-4475; 394 Meaderboro Rd., Farmington, NH 03835; berrybrookoxen@aol.com.

Drew Conroy teaches dairy farm management at the U. of New Hampshire, Thompson School of Applied Science, 291 Mast Rd, Durham, NH 03824-3562; 603-862-2629; oxwoodfarm@aol.com. He's the expert on training and using oxen as draft animals who wrote Oxen: A Teamster's Guide.

Mid South Ox Drovers Ass'n is for people interested in cattle trained for draft purposes (oxen). Demonstrations and newsletter available.

Midwest Ox Drovers Ass'n holds a wonderful annual meeting and has a regular newsletter ($10) focusing on education and sharing info: c/o Jeff Hieb, 1119 Porter St., Green Bay, WI 54301; 920-468-6420; oxdrover@execpc.com; www.execpc.com/~hiebej/.

Tillers International: Take a "Yoke Building and Fitting Workshop," the "Ox Driving Workshop," or one of the many other relevant classes in nonelectric skills offered by Tillers International, 616-344-3233; fax 616-344-3238; 5239 S. 24th St., Kalamazoo, MI 49002. They also sell ox-power publications and products: The Pride and Joy of Working Cattle, successful techniques for ox training, by Ray Ludwig; and In Praise of Oxen, by Terry James and F. Anderson, photos of Canadian teams. Membership in Tillers gets you the Nigh Ox, their newsletter. Other ox books from Tillers include Advanced Training of Oxen; Training Young Steers; Selecting and Teaming Oxen; and info on how to build an ox yoke, cart design, single-cow yoke design, yokes, yoke rings, and training videos.

Training Oxen: Begin training with calves, so they have a long time to get used to all that is involved. The old-timers looked for an animal with ambition and that "light-footedness." True draft breeds or dairy breeds are preferred for their docility, once steered. The old-time English Devon was treasured for its draft ability. Von Wagenen wrote that "the breed had a certain snappy activity and light-footedness." Nowadays Devons are rare; and Holstein steers make a fine oxen, too. Oxen are normally used in a set of 2.

Oxen can be trained to work by voice commands, combined with a prod or whip used by a driver who walks next to them, or to work using a harness and bit and driven with reins like a horse team. In either case you start by getting them used to wearing a halter and teaching them to lead. To drive using a bit and reins, train like a draft horse. Work with them at least half an hour a day. If you work right "backwards," and oxen yoked backward will be very confused! If your nigh ox, for example, dies, replace it with another trained nigh ox—or train a green steer. Don't try to use an off ox there. The old-timers in New England usually called that nigh ox, "Buck," and the off ox "Bright." That way they knew which side an ox was trained for by his name.

Gad. The voiced command is supplemented by the "gad" or "whip," traditionally a 4- or 5-foot length of narrow hardwood sapling with 2-3 feet of thin leather strap attached to the end. Let me make it clear that the gad is used for touches to get Buck and Bright's attention, to direct and manage them, rather than to punish. Some teams, in some circumstances, work fine with only voice.

Yoke. The traditional hitching system is based on the yoke, a large carved wood shape that fits over each animal's neck and is held there from underneath by a U-shaped bow under the cow's neck. To see how a yoke is made, check your local pioneer museum! You can make a yoke by cutting it out of a block of wood with a chain saw and trimming with a knife. The bow under the cow's neck can be made of any strong, flexible wood, steam-bent into that U-shape.

You'll be putting them into a series of yokes, of ever-increasing size, as they grow. To fit them properly with a yoke, start by tying them up standing parallel and with their sides 6 inches apart. Measure the distance between their necks and build their yoke accordingly. When they've grown enough that their sides are rubbing, it's time for a bigger yoke.

A modern variation is a bridle and bit on the animals by which they are directed from behind with reins just like with harnessed horses, but combined with a yoke.

Training Oxen to the Yoke. At the center of the single yoke that binds them together there is a metal ring. You fasten the tongue of the farm implement that they are to pull there, and that's it. While still young, they can pull a pole with something noisy attached to it to help them develop calm nerves—later a light sleigh or cart. At 18 months old they can start more seriously working. For tough work like plowing, even 4 yoke of cattle might have been combined in the old days.

Cattle Handling

Cows vary wildly in gentleness from a sweet pet of a Jersey family milk cow to a huge, mean, wild range bull. The following wisdom is specially applicable to working with range beef cattle, but there are wise reminders here for any handler.

Cow Psychology and Senses: Your cow's closest relative on the farm is the sheep. They're both herd-oriented, humble animals. (For least stress and best production keep 2 or more calves or cattle.) There will be a
boss cow, same as the boss goat described in that section. Large cattle herds will form smaller subherds with an order of dominance in each group. A cow's best sense is her smell. She can smell her calf 3 or 4 miles away. A bull can smell a cow in heat that is miles away. Cattle have good hearing, too. They dislike high-pitched sounds like the crack of a whip.

Cow psychology is influenced by the design of a cow's body. A cow has 360° panoramic vision. That means she can put her hind foot into the bucket or kick it over on you, and it's not a lucky accident for her. She can actually see beside and behind herself without turning her head. But cows can't see color. Everything is black and white to them, so it doesn't matter what you wear. They are very sensitive to stark black and white contrasts, though, and have poor depth perception. White lines painted across a road can look like a cattle guard to them. It's hard for a cow to tell the difference between a shadow and a hole in the ground so a dark shadow can scare her into going around it.

SECRETS OF SAFE CATTLE HANDLING

1. Move your cattle patiently, quietly. Avoid exciting or hurrying them because a running cow does its own unpredictable thing whereas a slowly walking one is likely to go where you want.

2. Cows follow the leader. If you can coax the first 1 or 2 through a gate, etc., the rest are likely to follow naturally.

3. To turn a cow you can make some noise and make yourself look large by waving your arms widely, but do this from an angle, not right in front of the animal because you may lose. Being straight ahead in the cow's way invites you getting knocked down and hurt.

4. Teach your cattle to come to a certain familiar call to get a treat of grain or a bale of hay. When you feed them frequently and handle them gently they learn to trust and depend on you. Then you can call and lead them where you want. (Always follow the call with the food reward or they'll lose faith.) This, of course, works best if they're hungry.

5. Cows are frightened of new places and made nervous by change in their daily routine. They don't take easily to learning anything new. They resent being forced to do anything. The best approach is true patience and a plan to outsmart rather than outfight them.

6. Build good fences and keep them repaired.

7. Build a corral and a loading chute.

8. A knowledgeable horse or dog can help a lot.

10. When dealing with a cow-calf pair, have a means of escaping available, such as a pickup that you could run around or vault into; the cow's protective instinct might get aroused, in which case she would attack using her head. She's most likely to charge you if her calf bawls. (The strong maternal instinct of beef cattle is a usually good thing. They've been known to protect calves successfully even against lions and bears.)

11. Before you help a calving cow, first halter her and tie her to a fence post, tree, or (worst choice) pickup bumper.

12. Be careful around a cow in heat. She may try to mount you.

13. Be even more careful around a bull. Never forget its potential danger. Never come near it without having an escape route in mind. Never turn your back on it. If possible always have a second person with you. If a bull does become threatening, hamburger it. Never let children into a pasture or pen that has a bull in it.

Cattle Housing

Don Fallick, Davenport, WA, wrote me: “Cattle lean on things. And they're heavy. Anything built for use around cattle simply must be very sturdy.”

Loafing Shed

A loafing shed for cattle should be anchored by posts at least 8 inches in diameter, extending below ground at least 3 feet. Old telephone poles work well. The phone company pulls poles when they get too rough to stand up to the punishment cattle will give it. Corrugated metal roofing is so good and so cost-efficient, it has virtually become standard. Such a loafing shed is cheaper than one built of cement blocks, and much cheaper than one with concrete walls, but it won't last nearly as long. A good compromise is to build the bottom 4 feet of the walls of reinforced concrete or reinforced cement blocks. Then build the top of the walls of wood.

Milk Parlor: Your “milk parlor” is an outbuilding where you will milk your dairy cow(s). Don Fallick says: “A milk parlor for cattle should be built similar to a barn, but for cleanliness I favor walls of concrete, at least at the bottom. If you use cement blocks, painting them will make them easier to clean. To fasten the frame tops of the walls to the concrete or cement blocks, set L-bolts in the top of the concrete, or fill the cement blocks with sand where the L-bolts will be set, except for the top course. Then fill with cement and set the L-bolts in every third block. The L-bolts will be used to bolt down the bottom plate of the frame portion of the wall. A slick way to position the L-bolts exactly is to drill the bottom plate first and install the L-bolts in it loosely, then use it to position the bolts in the wet cement. After the cement is dry, the bottom plate can be removed and the wall framed, installed, and bolted down.” Believe you me though, says Carla, it can be simpler than that.

Feeding Cattle

Any cow needs grass or hay, water, and salt. (There's lots more about pasture, hay, and silage in Chapter 8.) Cows that are giving milk have special nutritional considerations.
(see below). They all always need water and salt. Mature cattle are true symbionts, in that they cannot live without the help of millions of microscopic critters that live in their rumen and do their digesting for them! A cow's stomach is literally a big fermentation vat in which their friendly bacteria and protozoa are constantly digesting the food and fiber they eat.

NOTE: A cow is designed to eat with her head down. If your feed trough isn't low enough, her saliva won't run well.

**Water:** Cows need lots of clean water. If you have trouble with it freezing in winter, you can buy an electric heater that keeps the tank warm enough so the water doesn't freeze. Mike just goes out twice a day and chops a hole with the ax so they can drink and hopes for warm weather and a thaw. It's nice if you have a way to warm their water in winter, but it doesn't have to be warm. And, given a choice, cows would much rather drink unchlorinated water and thaw. It's nice if you have a way to warm their water in winter, but it doesn't have to be warm. And, given a choice, cows would much rather drink unchlorinated water and will drink more and produce more milk on it.

**Salt:** You can get various kinds of salt blocks. Some of them have minerals added. There is even a kind that contains a medicine to help fight the burrowing flies that cause worms in their backs. (Can't give that kind to milk cows.) Your block will last the longest if you keep it sheltered from the weather.

**Feed for Beef Cows:** You don't need to give beef animals any grain. In general, beef fat is one animal product there just isn't much use for. You can take some beef tallow on the end of a fork and use it to grease a pancake griddle. You could make soap with it. You can grind a little bit in with your beef hamburger, but it's a comparatively high cholesterol fat. Our cows for eating are entirely grass-fed: grass in summer, hay in winter. They've never tasted grain.

**Secrets of Dairy-Cow Feeding**

1. Provide lush pasture—or the equivalent in hay and supplements. In an average temperate zone your cow can be well-fed on pasture from early May to late November.
2. Pasture is most nourishing when it includes legumes (clover, alfalfa, lespedeza), several kinds of grasses, and a variety of herbs (natural, healthy “weeds” or fenugreek, lavender, marjoram, mustard, rosemary, sage, thyme, etc.).
3. Feed hay during winter: tender, green, cut just as it blooms.
4. Every day feed 2–3 lb. good hay per 100 lb. body weight of your cow, as much as she'll eat during winter. If you're feeding silage, give 3 times that much, since it isn't nearly as nourishing as good hay. If you do feed silage or green chop, best feed some hay too.
5. Feed only an amount of hay that she'll eat up before the next milking. Cows don't like stale feed and the surplus will be wasted.
6. You have the option of feeding your dairy cow only such good hay and/or good pasture. She will still produce plenty of milk for an average family.
7. When pasture or hay quality falls, your cow will give less milk.
8. If you supplement with grain (oats, barley, corn, wheat) and other high-protein foods (peanuts, soybeans, legumes, sorghum, milo, kafir, soybeans, peas), you can increase her milk production by 30–40 percent and prolong her production period. You can buy this type of supplement from a feed store or provide it home-grown. Store feed grains in a covered, metal container to prevent losses to rodents.
9. Feed supplements morning and evening at milking time.
10. If your cow isn't used to them, add them gradually, increasing the amount slowly to avoid bloat.
11. Start feeding supplements after calving and increase gradually as she produces more heavily, then taper off gradually as she slows in production, nearing the end of her lactation. Thus you match your supplementing to her milk production since the reason you're giving supplements is to replace the protein lost in her milk production. She normally peaks in production a month after calving, stays high for the next 3 months or so, then tapers down until the end of her 10 months lactation when it's time for you to stop milking her.
12. Every cow has a maximum ability to give milk, beyond which extra feed is just wasted on her. You can learn that by increasing supplement until her milk supply stops increasing. Then stop increasing—give her a little less than the peak amount for her 8-month production high. An average cow can use up to 1 lb. grain per 3 lb. milk produced. But with quality pasture or hay and ½ lb. grain each day, she'll give about 90 percent of her capacity. And that may be more than enough for your needs.
13. If you choose to supplement and/or winter her only on home-grown food, the easiest system is to give her corn and cornstalks starting in late summer. As long as the corn is still somewhat soft you won't need to grind it for her. Starting in about November add supplemental hay. Starting in December feed as much good hay as she'll eat, plus several ears of corn, ground, at each milking until the pasture is ready again in late spring. You can also give her root vegetables (carrots, beets—washed and sliced), crushed beans and peas, whole sunflower heads, cabbage, turnips, beet pulp, squash, pumpkins, buckwheat—actually, any grain (see animal-feeding instructions under that grain), and winter-growing green leafies such as comfrey and kale. It takes a lot of root vegetables or leafies to supplement for a cow. Figure about ½ acre of garden per cow to grow her supplementary feed at 25 lb. per winter day.
14. If pasture is overgrazed or the hay is poor-quality, she'll need extra-rich supplements.
15. Or, if she is gentle enough to wear a halter and be staked out—and many family milk cows are—you can put her out to graze on unfenced patches of good green grass in summer and make good use of feed that would otherwise be wasted. A staked-out cow needs a large water container nearby kept filled, especially if the weather's hot; or else somebody must lead her to her drinking place at least 3 times a day.
16. Know your cow's normal appearance. If she's fat, cut back on supplements. She could have calving difficulty from being overweight. If she's getting thin, give her more feed! If she refuses to eat, call the vet!

**About Roughage and Protein:** A dairy cow needs 2 kinds of food in her diet to be healthy: roughage, which can be supplied by any kind of grass, even straw; and protein. Alfalfa hay has both. Straw is high in roughage, low in
protein. You have to supplement straw with grain or good alfalfa hay, which is a high-protein hay. Straight grain isn't a good feed because there's not enough roughage. If you can supply your cow good green leafy alfalfa hay, almost any mixture of home-grown grains will be a fine protein supplement.

**More About Grain for Your Milk Cow:** Grains differ in food value. Barley is richer than oats, but more expensive than oats. A good grain treat feed for the milk cow is a mixture of half-chopped oats and half-chopped barley. Any grain that you buy for your animals should be chopped or ground before you bring it home. They can digest it better that way, so they'll get more food value for your dollar. If you raise your own grain, rigging up your own chopper is almost a must. Or you can use the coarsest grind on your home flour grinder. Whole grain is cheaper, so you can save yourself money by doing your own grinding. I give our milk cows about a half gallon of grain morning and night. That's really more than necessary. Oat-pea hay is a good winter feed for them. That, plus some alfalfa, contains everything they need—including enough grain.

**About Hay for Cows:** It takes a lot of hay. You don't need to give anything else but water and a salt block to nonmilking cows, but cows that are milking or getting ready to come fresh are grateful for some grain every day. Cows have the kind of digestive tract that needs a lot of roughage but also some protein. Alfalfa hay is ideal for them because it has both. But if you haven't got or can't afford alfalfa hay, you could use a poorer hay with a grain supplement to supply protein. Or a straw, alfalfa, grain combo. If you use straw, such as barley straw or oat straw (the stalks left after the combine has taken the grain heads), you should also give them some higher-quality food value in it to keep them in good shape. To winter a cow you figure about 2 tons of hay per cow per average winter.

**Cow Reproduction**

**Scheduling:** A milk cow can very neatly be put on an annual schedule. Keep your cow pregnant 9 months out of the 12. Dry her up about 2 months before calving time. (If her feed is mostly grass rather than grain and supplements, it's wise to dry her up 3 months before her due date.) The second time she comes into heat after calving (about 18-22 days after the first heat she'll be in heat again), put her with the bull or A-I. That way you are milkless only about 8 weeks of the year, and she is producing beef calves and replacement heifers about as fast as bovinely possible. Gestation is 285 days, about 9½ months. So she will calve again at about the same time next year, and you get 1 calf a year from her plus all that milk.

**Heifers:** It's better to not let a heifer get bred as soon as she is capable of it or you risk a difficult birth, a cow stunted for life, always a poor milk producer. They can conceive as young as 3 months. Don't let them conceive until they're at least 13 months old. To minimize calving problems, don't grain a heifer before she has her first calf.

**Cow Heats:** Usually her heat period is every 21 days, but individual animals can have a cycle as short as 18 days or as long as 24. Her first heat period after giving birth will be in 30-60 days. A cow stays in heat from 8 to 30 hours, on the average about 16 hours. If you notice heat, get her bred immediately, because the next day may be too late!

**Signs of Bovine Heat**

1. Restlessness, stamping around, twitching her tail an unusual amount.
2. She'll be doing a lot of bawling.
3. She may drop a little in milk production.
4. You may see redness and swelling around her vulva, plus maybe a mucous discharge there.
5. If you have other cows (even females), they'll be riding her in the manner of a bull.
6. If a normally peaceable heifer goes through your fence, it probably also means she's in heat.
7. If the neighbor's bull comes through your fence and breeds her, that's an absolute proof.
8. Lane Morgan warns, “Be alert. She may also try to mount you.”
9. If she lies down any time in the latter part of her heat period, she'll go out of heat.

**Breeding:** From the time of her first post-calving heat on, she'll have monthly heats until she's bred. A less frantic way of arranging her breeding than trying to get the A-I techie there first heat is to simply mark down her date, then make tentative arrangements for the next heat, which you now know the approximate date of—it will arrive in 18-22 days. Cows can thus conceive—and calve—at any time of year. The best schedule for cheapest food production is to time it so her calf comes in very early spring. Her first breeding may not take. (About 1 in 3 tries don't.) If not, try it again the next “month,” and that probably will settle her for sure.

**Bull.** You don't want to keep a bull unless you're running a serious cattle ranching operation. If you do, the bull needs more feed than a cow, but can make it on grass in summer and hay and roughage in winter. A bull for breeding should be at least 18 months old. A bull must always be handled with care. They are always potentially dangerous.

**A-I.** If you artificially inseminate, you can have a calf that's half anything. A heifer that hasn't had a calf before, or for safety's sake, that hasn't had 2 calves yet, shouldn't be bred to a bull of a larger breed than her own. Cow breeds vary too much in size. An unbred Jersey cow might weigh 600 lb. or even less before her first calving. On the other hand a Devon cow could weigh 1,600 lb. So you see, you wouldn't want to breed your Jersey heifer to a Devon bull because the resulting calf would probably be so big she couldn't bear it naturally. Breed her to a Jersey bull the first couple of times. Then you could try something bigger. Shorthorn is fine later on, because although the Shorthorn cow weighs about 1,200 or even 1,500 lb. on some of the Australian Illawarra exotics, the calf is not large.

The people who artificially inseminate are certified by the state after taking an A-I course. You can pay the inseminator to come, or you can take a course and do it yourself. The inseminator brings a kit in which he or she carries all kinds of frozen semen for you to choose from. Very fancy stuff—it can be from champion bulls of any breed you choose. The semen will cost an additional fee per ampule, price depending on the source. The cow has to be in heat for the A-I to take.

**Gestation:** The length of pregnancy varies somewhat, but in general a cow will calve 285 days from her date of service—in about 9½ months. If you don't dry up your cow that last 6 weeks it's hard on her, and the milk may get “strong” tasting.
CALVING: The same principles apply as with goats. Prevention of problems is the best cure. The dairy breeds of cows all calve easily anyway, as they are selected for that. It's some of the smallest and largest beef breeds that have the reputation of calving difficulty.

Because a cow's birthing instinct is to go hide in a woods and do it all by herself, it's wise to bring her into a pasture near the house in summer or into the barn where you're providing a warm stall with lots of clean bedding if the weather is awful. Do that at least a couple days before her calving date so you can keep a close watch on her. You'll know calving is getting near when her udder swells. Make sure it stays up. Alternately, you may see what looks like a mass up, make sure it stays up.

After that point, check on her several times a day. You have a big investment at stake here and will want to help or call the vet if she has calving trouble. But ordinarily your cow will calve, and you'll find her standing there nuzzling her baby, and you won't have to do a thing except provide the usual necessities of food, water, and shelter. She may very likely calve in the open. That isn't nearly the problem it can be with goats and sheep because calves generally are harder at birth.

If your cow is obviously in trouble and you live in the country near experienced neighbors, the first thing I'd do is ask them for advice. Most knowledgable cow people can help you judge what is happening very competently. If she isn't able to give birth after 3 or 4 hours of hard labor, call the vet to come. A cow is worth a lot of money and well worth what you'd pay the vet to get her fixed up. And then you save the value of the calf, too. A calf normally is able to stand, though awkwardly, soon after birth and nurse from its mama. If you're there when she calves, stay long enough to make sure that the calf indeed makes it onto its feet and found a teat.

Cow Down. Barbara Stone, Stites, ID, wrote me: "We had a cow that had just calved, but she had lain in such a position that she couldn't get up. She was in the middle of the field, but she found a place where she had her head downhill and her back area uphill. This had never happened to us before, so we didn't know exactly what to do, but we knew she couldn't stay there too long. With the help of a neighbor we got her feet dragged around with both areas on the same level. Put her on her knees and held her so she'd stay there. Within just a few hours she was up as if nothing happened. If this happens again, and it probably will sometime, we'll know what to do. If no one is around to help, use the tractor or the pickup, tie a rope around the front legs and carefully roll them around until they are straight. Watch the neck that it doesn't get hurt. All of these things a person has to learn sometimes the hard way. After the animal is up, make sure it stays up."

A cow might be down if she's been injured from slipping on a slick surface, or had a blow from another cow, or by calving, or by disease. A "downer cow" is indeed a crisis. She needs to be kept comfortable, fed, watered, and treated as needed. Pro cow operations use a "downer cow skid" to move her if moving is needed. (It takes at least 2 or 3 strong people to roll a downed cow onto even the lowest skid.)

NOTE: But if a cow goes down and can't get up just before or right after calving, I'd start by calling the vet quickly in case she has milk fever.

Newborn Calves

Take out a big towel or blanket to dry off the newborn calf with a good rubbing. Check to make sure it's in a relatively nice place. Calves are tougher than kids. If you want the cow and calf moved, just pick up the calf and carry in your arms. The cow will follow. She'll try to hide the calf as soon as she can. That's called "brushing up," and it's an instinct cows have. She'll go to the hiding place several times a day to feed and check on it. (Goats, on the other hand, will stay right by their babies.)

We usually give the newborn calf its Boser vaccine and maybe some A and D and Combiotic and hang around until it stands and finds its first meal. Even if you leave the calf with the cow you've still got to milk the mother out yourself at least once a day. That's because any milk cow in her second (or more) lactation gives much more milk than a newborn calf can use, and she will be miserable and risking mastitis if you don't help by taking the extra milk.

BUYING A YOUNG CALF: You can often buy a calf from a nearby dairy or farm. If you just want a calf to raise for meat, a male calf of a dairy breed is probably the cheapest to buy. A dairy-beef cross would give you a little more beef; they grow faster and have a meater carcass. Be sure you have a healthy one. A thriving young 'un holds up its head — back straight, tail out a little. A calf that won't stand or huddles in a corner with its head hanging, back hunched up, and tail down between its legs is probably sick. A bargain calf that brings disease, parasites, and vet expense to you—or even dies—is no bargain. It's best to take care and a little time in buying, though it will cost you more. Ask: When was the calf born? How many days of colostrum has the calf received? What vaccinations has the calf received? What diet is he on right now? How much milk per day? How many feedings per day? How much grain or hay?

milk. Later add a water supply and a hay manger if hay will be fed.

**White Muscle Disease.** We had a calf die of this. It was very stiff in the joints, moved little, slowly, with obvious difficulty, and was in poor health, generally. It couldn’t follow its mother and so didn’t get enough to eat. There is a lot of white muscle disease in our area, and it’s important that we get a calf immunized against it as soon as possible after birth because it’s just about impossible to cure once it sets in. We try to give the immunization shot the same day the calf is born. You can mail-order these and other serums or buy from your vet or vet supply.

**Chilled Calf.** If you find a calf prostrate, shivering, with tongue slightly protruding and eyes sunk in—one that cannot get up or eat due to the chill on an unseasonably cold night—carry it into the house. Lay a towel in the bathtub. Lay the calf on the towel and a blanket on top and draw in enough hot water to stop the shivering. In the meantime get a hot place ready for after it comes out of the tub so it doesn’t get chilled again. Keep the calf warm even when it seems to be pulling out of it. A chill may give it a fatal setback.

**Surplus Calves.** These are never just killed and discarded like kids may be. Even a newborn calf is worth at least $75 or can be butchered for meat. But a normal cow gives plenty of milk to meet both your needs and the calf’s.

**Milk for Calves:** You can take a calf from the mother anytime from birth on. If you take the calf away immediately, you get it without prejudices about how it should eat and without too much energy to fight your ministrations. If you wait 4 days, however, it has been well-started by the mother, but the mother’s milk production in the long run may benefit more if you take the calf off her immediately and milk her out twice a day.

**Colostrum.** Feed the calf all the milk you get from its mother for the first 4 days of milking after calving. You can refrigerate surplus until needed. Don’t use it yourself since it’s brownish-yellowish and not very appetizing looking for people food, and more importantly it contains antibodies the calf urgently needs. After that the colostrum taste is out, and you can use the milk, too. The colostrum milk is fine for pigs and chickens as well as the calf, so you don’t need to throw any away.

**Calf Adoption.** A dairy cow can easily raise 2 or 3 calves. To put a calf on a cow that’s not its natural mother, it works best to restrain the cow while the calf nurses until it learns how to sneak a meal from behind. Some folks put vinegar on the calf and on the cow—on their noses and other places—to try to fool the cow into accepting the calf more readily.

**Milk Formula for Calves.** If you have no colostrum, give the calf warm milk with egg yolk beaten into it. Cold milk can kill a calf. The egg yolk makes the first meal a little richer and thicker. Continue to give the milk and egg yolk mixture for several meals and return to it if the calf does poorly after that. After that, feed milk from another cow, just as it comes from the cow. If you don’t have that, you can feed fresh goat’s milk, diluted 1:1 with water. Lacking that, feeding reconstituted dried whole milk is next best. Dried nonfat milk is not as healthy but can work.

**How Much Milk?** A quart or so per day to start with, then work up to 2 qt. per day at 2 weeks, then 3 qt. per day at 3 weeks. It depends also on how much the calf will drink. You can give more of the cow’s milk than of a powdered milk—water mix or goat’s milk. Calves of different breeds, hence different weights, will take relatively more or less. A larger calf will be drinking 2–2 ½ qt. at each of its 2 daily feedings. The older the calf, the more it will take. Too much causes scours. A big calf would happily drink much more milk than it is ordinarily given. We force the calf to share his milk with us because we need it too.

**Temperature.** The milk should be warmed to body temperature, about 100°F.

**Calf Bottle/Feeder.** You feed them either out of a pan or from a calf bottle, calf feeder, or a calf group feeder (a box with several nipples). A calf feeder is a bucket with a nipple attached to the bottom. If you’re going to use the calf feeder you’ve got to start with it—the very first time you try to feed the calf. He’ll get a fix on whatever he is sucking when he gets his first good swig of milk and will be hard to change over. You coax the nipple into his mouth the first time. Same with a calf bottle, which is a big plastic bottle with the right-sized nipple. Try to stay with small calves drinking out of a calf bottle. Otherwise, they may yank the nipple off, end up inhaling their dinner, and get clinical pneumonia. The calf group feeder is the latest and greatest thing, especially for mass production of beef calves. Let’s say you have 5 calves in a pen. At feeding time you bring their milk in a big bucket and pour it into the group feeder. The group feeder sits on legs on the ground or is hung from or attached to the wall. It has 5 equal-sized compartments to hold milk, each of which is attached to an outside calf-sized nipple. The milk-holding part has marked lines on the inside like a measuring cup so you know how much you’re feeding. You pour the milk into the little trough; the calf sucks it out through a nipple. Have the group feeder high enough so young calves suck in the natural head-up position.

**Pan Feeding.** Or use a stainless-steel pan (but any kind will do) about 6 inches deep and about 1 foot across. I warm my milk and egg mix right in the pan. Make it a little extra warm to compensate for chilling on the trip to the barn. The calf has 2 strong natural instincts that you have to consider when you’re breaking him to a pan feed: one is to reach up to feed; the other is to suck on a nipple-type object.

So do this: Cup your left hand slightly. Dip your hand in the warm milk. Slip your middle fingers into his mouth. With your other hand scoop up milk and pour it into your feeding hand. Some of it will run down the grooves between your fingers and get into his mouth. You need some-
body to hold the pan while you are doing this. And the calf needs to be lying down to make it easier for you. You may have to spend a long time just doing this. Now try to gradually lower your hand into the milk. He'll suck up the milk and it will go into his mouth. Wiggle your fingers in his mouth a little if he seems to be losing interest. It takes a little effort to get him pan-broken, but once he is, all you have to do is take his pan and set it down and get out of the way. That's helpful when he grows to 200 lb. Note: It's actually healthier for a calf to nurse with his head up than down because that's the way he's designed—so there's another advantage to the bottle method.

**Frequency.** Feed the calf every few hours (5 times a day) until you're sure you are getting food down it. Then go to 4 times a day for a few days. Then feed him morning, noon, and night for a few days. Then only twice daily. He will be a ravenous glutton, but don't give him all he can drink, as it will make him sick. Twice a day continues until you're ready to start weaning.

**Calf Scours.** When we have a baby calf with scours we put him in the warmest, driest place possible, give him an extra calf starter pill if it's very bad, and give him half a 12-ounce bottle of Kaopectate. Kaopectate is a mixture of real fruit pectin and kaolin—a natural clay. It really helps. Then I give less milk and sometimes make it less strong by water—wait to wean until they are 6 or even 7 months old. After Mum dries up in preparation to calve again, the naturally nurse on this schedule, and thus don't get weaned fully until about 6–8 months of age.

**Late Weaning.** If the cow gives plenty of milk for your needs as well as the calf's, you can let it nurse until time to butcher it for veal or baby beef or until she dries up to have her next calf—and save money and hassle. This is basically demand feeding. The calf is shut away from Mum either at night or in the daytime, so the family gets at least one milking a day for their use. The calf eats grass or hay as wanted, and grain for treats and teaching and taming but not a regular diet of it. You can do the same thing with a bucket- or bottle-fed calf when you have abundant milk—wait to wean until they are 6 or even 7 months old. After Mum dries up in preparation to calve again, the naturally nursing calf will give it up forever (in case you have a calf that makes a liar of me and continues nursing, you can buy an anti-sucking device from Nasco), and will be physically ready to, even though still in the same field. Beef calves naturally nurse on this schedule, and thus don't get weaned until about 6–8 months of age.
able to sustain himself on other foods. A husky growing calf will need an acre or more of pasture, or less pasture plus several pounds of good hay each day. On this system he gets more and more milk at first—and then gradually less and less, until he's finally weaned at about 4 or 5 months.

Early Weaning. When grain is cheaper than milk, producers tend to push calves to early (premature) weaning. In this case, you start feeding chopped grain and hay and pasture to calves as soon as they will take it. As soon as they are eating this other food, the milk is cut back. Some growers take pride in a calf that's weaned by 6 or even 5 weeks of age. But be careful of trying this because too abrupt a switch from milk to solid food can result in temporarily stalled growth. Don't stop the milk ration until the calf has been eating grain for at least a month. The calf on a grain-based diet will grow fast, but only when mature enough to digest it efficiently. You can gradually increase the amount of grain and hay, if not pasturing, until a 6-month-old calf may be eating 4 or 5 lb. grain a day.

Winter Feed for Weaned Calves. Feed as much good hay as they'll clean up, about 2 lb. per 100 lb. of their body weight each day. Or give corn stalks and cobs; 3 lb. of that equals 1 lb. of hay; or grain; figure 1 lb. of grain equals 2 lb. of hay. The important thing is to feed what you naturally produce or can economically buy nearby; plant byproducts of almost every sort. But if you want organic meat, of course, then you have to be careful what goes into him. The easiest thing is typically to feed good hay plus some grain.

HALTER-BREAKING: Break an animal to lead while it is a baby, small enough to manage. You can't break an 800-lb. bull to do anything. So put a collar on it. Let the children tie something to the collar and lead it around and around and around until it gets the idea. Keep this up regularly and when it's big you will still be able to put the rope through the halter ring, give it a little tug, and your 800-lb. beast will follow docilely.

HEEL FLY: I just discovered a new one here. It's a fly called the heel fly that lays eggs in summer under the heel of a cow. The eggs hatch and the larvae crawl clear up the leg of the cow through blood vessels to live on her back. The next summer they bore an opening, change into flies, and leave the cow to find another host. I've got one cow that has this (she had it when I bought her), and the vet tells me at this stage there is nothing to be done. The preventive, an internal medicine, has to be given in the fall of the year. He says anything strong enough to kill them at this stage would kill her too. Oh, yuck!

Cow Butchering

AGES: What you'll call the meat depends on what age the cow was when butchered.

Veal. A calf that is butchered at 8–10 weeks will weigh about 180 lb., dress out to about 100 lb., and be called "veal." Veal is light colored and mild flavored and very tender compared to beef. Veal goes well in recipes for young chicken. In Victorian days when they really went in for a big variety of exotic meats for the tables of the rich—blackbirds in a pie and the gamut to a haunch of venison—veal was a delicate and delicious regular. But from the point of view of someone raising their own meat, veal is an uneconomical meat because in that last 8 months your calf will put on so much weight that to butcher him before is to be woefully inefficient. However, you can butcher a calf any time from the day he's born, and meat's meat.

Baby Beef. Breeds vary considerably in size, but, on the average, a calf 6–8 months old will weigh 300–400 lb. and about 60 percent of that will be edible. A calf that age is called "baby beef," a meat about halfway between veal and beef.

Beef. A yearling may weigh from 800 to 1,000 lb. An older animal may weigh 1,200–1,500 lb. or more. The butchering principles are entirely the same—only the scale is different. But I would recommend butchering no earlier than 15 months. Let's assume you get a spring calf. You give him milk that spring and summer and he's costing you milk and trouble. Throughout the winter you have to feed him hay, and that's money and trouble again. If you butcher him the next spring, well OK—but wait. If you let him go, he'll feed on all that good free summer grass all the second summer of his life, on through the fall, up to the time you would have to start feeding hay again, when the ground gets covered with snow. That's the natural time to butcher him. He'll put on weight at an amazing rate now that his basic frame is built, and that grass feeding is cheap and easy for you. If you let him go even to 24 months (when he is finally mature in build), he will continue growing all that time.

NOTE: Read "Introduction to Butchering" in Chapter 8 before you begin butchering your cow.

KILLING THE COW: If the animal is gentle enough, or if it is halter broke, maneuver it to where you want to butcher, preferably right beside the hoof you have in place for hanging it, because with that kind of weight it's a lot of work to move it. Hopefully a heap of grain or a salt block will persuade it to go where you want it. Don't kill the animal when it is excited or has been running. If you've just had a big struggle getting it moved to where you want to kill it, go away for a few hours and let it calm down before shooting. That will help the final quality of your meat.

You could use a .22 but a .30-30 or bigger is surer. Try very hard to get it right with the first shot. If you miss with the first shot, the animal may either go on a rampage and hurt somebody (come right through the side of your corral), or it may just turn around and that will make it even harder to get another shot into the right place. We had a really wild Angus heifer that Mike had to shoot 3 times to get down. She turned just at the last and wrong moment on the first shot. So you see, it can happen to anybody, even to a great shot like Mike.

Anyway, shoot your cow by mentally making an "X" with the top points on each ear and the bottom points on
each eye. Shoot where the lines cross. Tie the cow up if you can and 1 shot will be enough. Shoot straight in. You'll have to move around to do it, or wait until the cow turns to face you. Take your time and do it right. If you get it right the cow will drop to the ground instantly, exactly where it was standing when you shot it.

**Sticking:** As soon as the cow drops, start running toward it with your best knife to cut the throat. (Don't fall on it!) You want to open up the throat while the heart is still beating so it will pump the blood out well.

I used to think you were supposed to cut across the throat from side to side, under the ears or an inch or so back, clear to the backbone on either side of the esophagus, until the head was about half off. It helps if the head is slightly downhill. That's how we did it. But I've since heard that a better way is to cut the throat lengthwise, from the jawbone to the breastbone, and then push the knife under the breastbone and between the first ribs into the chest cavity to cut the carotid arteries. Try not to cut the heart, so it will continue to pump out blood as long as it works. Work the front leg back and forth for a while as if the animal were walking to help expel the blood. Wait until it gets completely quiet. Kicking reflexes will go on for a while and could hurt somebody. Keep the head downhill and the flow of blood unobstructed while you're waiting.

**Moving the Cow:** If the cow didn't drop where it was handiest for you, and you have a tractor or other strong vehicle, use that to drag the body where you want it. Use a towing-type chain. Fasten one end of the chain to the cow around its cut neck, the other end to the vehicle. Then drag the cow to the place you want to skin and gut it—preferably a place where you have a way to hoist it.

**Hoisting the Cow:** A tractor with a fork-lift (hoist) is the handiest thing for moving and raising your carcass. Cut a place to hook the singletree ends under the tendons of the rear legs. Cut on each hind leg just inside the back of the "knee." Do it just above the first joint. You will be over 2 feet up from the hoof. Don't cut the tendon. Hook up the singletree with the tendons.

Fasten the singletree chain to the fork-lift and raise the animal. If you are working with a pulley or a "come-along," which is a 1-person pulley, hook that up to your singletree and haul away to get that animal raised off the ground, upside down, to a height at which you feel comfortable working. From 18 to 24 inches above the floor is good.

**If You Don't Have a Hoist:** It's hard to do what needs to be done with the animal lying on the ground—but it's not impossible. We've done it that way. It's the same as when you kill an elk (a cow-sized game animal) in the woods. If the cow is lying on the ground, first cut the head off. When you have the skin and meat all cut through, give the neck a hard twist around and around until you feel it break. Then finish cutting it off. Now maneuver the animal onto its back, exposing the full extent of belly topside. Doing that to a big cow is hard. Popping up one side with a stick for a brace may help. Then use the directions given below, except with the cow on the ground the innards will not fall out by themselves—you'll have to help them out. Proceed to "Gutting the Cow."

**Cutting the Head Off:** Usually a cow is gutted before being fully skinned, whereas sheep, rabbits, or goats are skinned first. Finish cutting around the neck. Turn the head with a hard twist around and around until you feel the neck break. Then cut it all off. You'll have to finish with the saw. Some people use beef head meat to make sausage. Most people discard it except for the tongue. Cut out the tongue and put it in your organs bucket.

(After having already sold 1,500 of these books, I discovered to my awful embarrassment that at this point I left out how to remove the innards of the cow! Bad enough printing pages upside down, but that was worse. All those people depending on me—and I told them to get the animal raised up off the ground and then directly to commence sawing off steaks!)

**Gutting the Cow:** If you have a male you start by cutting around the genitalia, including a patch of skin around it. Then you slit up the midline (I'm assuming the animal is hanging by its heels so "up" means toward the hind end), cutting the hide first and then around the anus so that you free the gut for tying off with a twine, so nothing in there will come out. You lift free the genitalia along with the cord and then proceed to open the hide on down the belly line. The animal isn't skinned. You'll skin it after you gut it. Most folks run their hand inside the skin as they are cutting down from the outside to push back the intestines and prevent the knife accidentally cutting them open since they are right underneath. If you hear a hiss you did it. But don't despair. That happens a lot to amateurs. It's happened to us, and it needn't harm the meat. Just struggle on. Saw through the H-shaped bone, which is called the "aitch" bone. It's between the hind legs in front of the rectum. Cut all the way down the front before starting to pull the innards out. Have your washtub ready; they are big and heavy. After they are halfway out and the part that's out is in your washtub, you can take time out to find the liver and heart.

**Beef Heart.** This is really good food, but to find it you'll have to look hard. It's encased in tissue and fat. Cut it free and put it in your organ pail. (Later, back at the house, I give it a good rinsing under cold water, slice, and bag for freezing.)

**Beef Liver.** This is big and easy to see. Remember to get the gall sac off the liver. You have to cut it out plus discard the part of it by the liver to do it safely, but there will be plenty of liver left. Back at the house, give the liver a good rinsing under cold water and then slice it very thinly and freeze in meal-size bags. Remember to eat up the heart and...
liver fairly quickly because they don't keep as well as the rest of the meat. If you don't have refrigeration, you'll have to have beef liver for dinner that night and every meal thereafter until you use it up, because it doesn't cure or can well.

**Finishing the Gutting.** Cut through the breastbone now on down to the throat to finish opening up the belly side of the animal from tail to throat. That will make it easy for you to finish taking out all the innards and the tongue, which is very good to eat.

After you have the innards all out, stop and give your hands a good washing in the bucket with vinegar water. Sharpen your knives, if they need it. Now go back to work. Skinning is next.

**Skinning the Cow:** This is the hardest single butchering job I can think of—a long job. But stick with it because the cooler the animal gets as the body heat leaves, the harder it is to skin. The reason you butcher a cow first and skin it afterwards is that if you skinned first, those innards might wait in there too long for the meat's good. Use the goat-skinning instructions. There are good directions for handling your hide in the tanning section in Chapter 8.

**Halving, Quartering, and Aging the Beef:** If you cut the tail off and skin the top part of it, you have the makings for oxtail soup! For the rest of it, read on.

**Quartering the Beef.** Pork is usually hung in halves and best left just overnight because aging doesn't improve it, but beef is so big you need smaller sections just to be able to carry it around and to help it cool quicker, and aging does improve it very much. If you do the quartering right, each quarter will turn out to be from 90 to 140 lb., depending on the age of finishing—and all 4 pieces will be nearly of the same weight.

Saw down the middle of the backbone to divide the animal into equal halves. Use a wood saw or a chainsaw or whatever you can lay your hands on. It's a mean job, and it helps if there is more than 1 person so you can take turns—one resting while the other is working. Now standing on the "belly" side and starting with the rear end of the cow, look inside the chest cavity to see where the ribs begin and count them. Cut between the third and fourth rib from the rear. When you get the 2 ribs cut part way apart, make a slit between the fourth and fifth ribs and tie a rope through there. That's preparation so the front quarters can be hung by that rope in whatever place you have ready for hanging the quarters. Have someone else hold the front quarter off the ground while you finish separating it, then carry it to the hanging place and hang there by your rope from a rafter or whatever. Get the other front quarter the same way. Now let the hoist down enough so you can untie the hindquarters, and then move them to your hanging place for aging.

**The Hanging Place.** This should be someplace cat-proof, dog-proof, and fly-proof, if possible (you can use meat bags—even make your own out of old sheets or some such—to help with the fly problem, or, better yet, butcher out of fly season). You need a cool place, too, and if you haven't butchered in cool weather you'll want to put the animal in a neighbor's or butcher's walk-in cooler. But a lot of butchers won't let you use their walk-in cooler now because federal laws have made it illegal to have un-inspected homestead-type meat in there with the high-class fast-food-type meat.

**Aging the Beef.** Tenderizing the beef improves the taste. How, I don't know, but it really does. Age it at least a few days and preferably a week or even a little more. Aging just means letting it wait before you go ahead and cut it up, wrap, and freeze or can. The meat doesn't rot right away because there aren't any microbe seeds in there. It was just alive. When it does start to go bad, it'll start from the outside and work in, so you have plenty of warning and can trim off any bad parts. But handle the tallow (fat that you want to make special use of—maybe for soap) and hide promptly. Once they start going, it's impossible to get the bad odor out.

**Cutting Up**

**Timing.** When the time does come for cutting up the quarters, it's a good idea to do it no faster than a quarter at a time. I mean a quarter per day. Another day of aging will improve the remaining beef, and defrosting could be a disaster for food already in your freezer when you put the meat in. Defrosting is what happens if you suddenly put a whole beef in there. In my experience it takes nearly 24 hours to get 1 quarter of beef all frozen in a large chest freezer. Or rent a locker or make arrangements to have it quick-frozen and then move it all to your freezer.

**Making Cuts.** If you're a pro you know exactly what you want. If you're not sure what you're doing, cut steaks off the wide ends, make roasts out of the narrow ones, and hamburger out of the mistakes. Mike thinks that ½ inch
is a perfect thickness for steaks. I like ½ inch, but he
thinks that's really too thin for any beef steak except maybe
round. He says any steak with a bone in it should be at least
⅓ inch thick. Some people do cut them an inch or even an
inch and a quarter, but I think that's way too thick. But, bot­
ttom line, how thick you cut is entirely a matter of personal
preference. Or economy—a thinner cut yields more steaks!

To saw out steak, cut with your knife all around the
bone. Then saw through the bone. The tenderloin is the
most tender steak. The round is the toughest. The muscles
the cow uses the most (round, hind leg) are the toughest.
Don't trim off all the fat—you want some around the edges
of your steaks for flavor.

**Hindquarters**

1. Cut the leg from the body.
2. Starting from the top of the leg, slice off the round
steaks clear down to the "knee" joint. When packaging,
if you cut the round steaks in half, they will be easier
to thaw.
3. The next portion of the leg (working down) will be­
come roasts. If you make them about 2 inches thick or
more it's fine. You are slicing the same as a steak only
much thicker, and that makes it a roast. If you trim out
the bone that can be a soup bone for you.
4. When you get down to where there isn't so much
meat, cut the rest of the lower leg into chunks for soup
bones that are called "shank boil." Or you can trim off
the meat and put it in your hamburger pile, if you
want.
5. Cut the belly abdominal muscle flap away from the
rest. That goes into the hamburger pile.
6. On the piece that's left you can start from the "front"
end, taking odd rib steaks. There will be 11–14 inches
of rib steak on a big beef, 6 or 7 on a smaller one. The
big hind end of the loin is the rump roast. Saw it off. It
will have something of a triangular shape.
7. Now start taking off sirloin steaks. The porterhouse is
in the middle. The T-bones are clear to the front.

**Front Quarters**

1. Remove the "arm" at the joint. Have 1 person cut from
underneath as the other pulls the arm upwards. You've
got to force it on up and out, under and around that
shoulder blade. You now have an arm plus the rest.
2. Cut off the top one-third of the arm for a "blade roast" and
trim off some of the fat. Don't trim the roast completely
clean either. Some fat around it helps the taste
when it's cooking.
3. The next 6 inches can be a roast. And so can the next.
Make it into what you like. It could be a big roast or a
small one plus some stew meat.
4. You can make the rest of the leg into stew bones or
trim the meat away from the bone for hamburger.
5. With the meat saw, separate the ribs from the back­
bone and its accompanying muscle bundles—the
 tenderloin and backstrap. Saw about 8 inches from where
the ribs connect with the backbone.
6. You can see what your steaks are going to look like
now. Cut off the steaks. You waste less if you saw each
one out, but that requires tremendous time and effort.
If you're not up to that you can bone out the 2 muscle
bundles and make rib eyes of the larger muscle and
tips from the smaller backstrap.
7. The neck end, which you can identify because it curves
a little upwards, can be made into roasts and stew meat.
8. The remaining rib area is a vast ordeal of spareribs and
soup bones. Here you have the most work for the least
desirable cuts. Starting from the rear, cut between one
rib and the next all the way until they are completely
separated. Then between the next and the next all the
way and so on. Then saw across the individual ribs at
6-inch intervals or as your cook likes them. You'll end
up probably sawing each rib thus into thirds.
**Beef Recipes**

- **Dried Beef** Use the jerky recipes in Chapter 8.

- **Mock Turtle Soup (Calf's Head Soup)** Boil a beef or veal head (and feet, if you want) until the meat separates from the bones. Remove bones. Cut meat into 1-inch pieces. Boil an hour more (until tender) with an onion and bay leaf. Add 8 sliced small onions and 1 T. parsley, and season to taste with mace, cloves, and salt.

- **Basic Beef Stew** Cut 4-5 lb. of beef stew meat into 1/2-inch cubes and brown them in a small amount of fat. Add 2 qt. small carrots (or 8 chunked large ones); 3 c. onions, quartered; and 3 qt. peeled potatoes, quartered. To this very basic stew, add your own favorite seasonings, cover with boiling water and simmer until all the meat and vegetables are tender.

- **Canned Beef Bone Soup** Saw or crack fresh, trimmed beef bones to release their flavor. Rinse bones and place in a large stockpot or kettle. Cover bones with water. Cover pot. Simmer 3-4 hours. Remove bones. Cool broth. Pick off meat. Skim off fat. Add meat removed from bones to broth. Reheat to boiling. Fill jars, leaving 1 inch headspace. Adjust lids. Process in pressure canner only: pint 75 minutes, quart 90 minutes. If using a weighted-gauge canner, set at 10 lb. pressure at 0-1,000 feet above sea level; at higher altitudes, set at 15 lb. If using a dial-gauge canner, set at 11 lb. pressure at 0-2,000 feet above sea level; 12 lb. at 2,001-4,000 feet; 13 lb. at 4,001-6,000 feet; 14 lb. at 6,001-8,000 feet; or 15 lb. above 8,000 feet.

**What's the Beef?**

There are more myths out there regarding cows than regarding any other domestic livestock. Why do cows get picked on? Is it because of their size that they're less likely to be part of a family operation and more likely to be in a commercial ranch setting? Because they aren't cute like goats? Cuddly as rabbits? I am astonished to find outrageous untruths/ignorance, even in a how-to book that says it's going to tell you how to raise a calf for beef. Here's a partial debunking.

**Myths and Truths About Cows and the Beef Industry**

No. 1: It is best to use land to raise cereal grains for people, rather than using it to feed animals.

The answer is ... not that simple. Not all land can raise cereal grains. The most efficient and productive use of land is to raise meat animals off the parts of your land you can't cultivate—hillsides, woods, really dry places, or places with really short growing seasons. Those are natural forage areas. It would be truly wasteful if there were no grazing animals for the natural forage areas that grow enough cheap grass to fatten a cow in spring or enough brush to maintain goats. Even if all your land is tillable, you may not want to expend the time and labor to garden or farm intensively more than a portion of it. You may want to have a woodlot or to leave the land as near a natural state as possible. Your grazing livestock will do the work for you and harvest and put to good use the plants growing on that uncultivated land.

No. 2: If you don't feed grain to a growing beef animal, it will take 5 years to mature enough for butchering—and then be tough.

False. I can't believe I'm looking at that in a book about cow-raising, but I am. The truth is, beef animals, like other animals, don't grow as fast on natural as on concentrated feed; they don't get as big; they don't give as much milk. But they grow almost as fast (not counting fat) and mature at the usual time. And if you want tender beef, butcher a young animal, age 1-11/2, not a 5-year-old! It's that simple, grain or no grain. The "tenderness" created by excess grain-feeding is a false tenderness created by the presence of fat inside the muscle.

No. 3: Steers for beef are raised in feedlots under crowded, inhumane conditions.

Again ... it's not that simple. It used to be that most farmers had a few calves and finished them on their own grass and grain for home use and market. Now family farms still may raise 1 or 2 calves for beef, but overall the beef industry has become very specialized, divided between brood cow—calf and feeder operations. I think it's important to understand that cows are not ordinarily fed grain in the cow—calf operations. These cows eat grass in summer and hay in winter. The herd of brood cows stays on the farm and calves every year. The farmer sells the calves when they are between 400 and 800 lb. They are sold at so many cents per pound through the auction ring.

The calves sold by the cow—calf operation at auction may either be bought by a middleman or by a feedlot operator. The middleman is somebody who has surplus grass and wants to make his land pay by getting those calves onto it to eat the grass and put some more weight on before their return to the auction ring. Typically, the middleman doesn't keep brood cows, or doesn't have enough to eat up all the green bounty of his summer pasture. By buying extra calves in the spring, when his grass is starting to come on well, and selling them off in the fall just as his grass is dying back for the winter, he gets a profit from his grass crop. The difference between what those calves weigh when bought in the spring at the auction ring, and what they weigh in the fall, multiplied by the price per pound paid for them, equals the middleman's gross profit for that summer's operations.

Then, unless they go to the grass-fed beef market, which exists but is still comparatively (pathetically) small, they go to the feedlot. But it doesn't have to be that way. The calves could continue to feed, like their mothers, on grass and hay, to butcher weight.

No. 4: Trees are being cut down to grow beef.

Not that simple. A good bit of the U.S. landscape once was forested, but now isn't. Cows may or may not be what grows there. It would be nice if those trees could be replaced. Everywhere trees are being cut down at an appalling rate—to make toilet paper, paper towels, book paper, etc. After the quick profit from timber sales the land is then either tilled or ranched unless it is reforested. In Central America, tropical forests are indeed being cut down by cattle ranchers who want the cash profits of selling beef to fast-food restaurant chains. (This isn't a large issue in the United States, because we've already cut down most of our original forests and forgotten they were ever there.)

Logging isn't the cows' fault. The cow—of all animals—is the one best suited to take the roughest of all feeds—native grass—and turn it into quality human food. Like the buffalo, the cow is most naturally a dweller on grassy plains. Cow-calf operations are best situated in good, natural-grass forage areas. There, feeding your cows grass is no problem and they'll make the milk to feed their calves. If you have even a few acres of decent pasture, you can get a
lot of nice milk and meat off it for your family by means of a cow or cows, anywhere. For untillable, or untilled, grassy land, cows are also an excellent and ecologically appropriate choice. Cows can also graze among growing trees.

No. 5. Cows are fed grain that could end world starvation.

Not that simple. Cows are fed a lot of grain, which, as said, they don't actually require. But if cows weren't eating it, it probably wouldn't go to poor, starving people either because the first problem would be: Which poor, starving people? And the second would be: Who pays the grain grower for it? It costs money to grow every bushel of grain. Grain growing, like all farming, is a business—nowadays a petroleum-based business. The commercial farmer buys seed and makes his payment on the land and machinery and, if it's not an organic farm, also buys nitrate fertilizers, pesticides, and herbicides. When he finally harvests his crop, obviously he can't give it away or he'll not make his land payment, and some more practical farmer will be working it instead. So his grain crop gets sold to nearby bidders with money to buy—among them feedlot operators.

Woody Bernard, the Dairy Agent in Washington State who kindly reviewed this chapter, adds another good point: "Animals utilize byproduct feeds that people won't eat." That's so true. They eat the leftover from pressing seeds for oil, the corn cobs and stalks left after the corn is harvested, the beet pulp after sugar is extracted, seed hulls after the seeds are removed, and so on. Cows are wonderfully complementary to human beings because they can digest and change their food into good foods for us—milk and meat—all from food sources that people cannot eat.

No. 6. Cows have to be fed grain.

Not that simple. You can raise a calf for beef, and a cow for milk, and never feed a mouthful of grain, using instead quality pasture, good hay, and winter vegetables. Beef animals raised this way are called "grass-fed beef," and they're the best that money can buy: best for the environment, best for your health. But cows are generally fed a little grain even on a homestead operation because they love it so much. It helps gentle them. It's a wonderful way to get them to do what you want. They are natural grass eaters, and it's natural for them to love grain, which is grass seed: the goodness of grass in a concentrated form. Grain provides extra nourishment if you want to build up the health of an animal near to calving, or keep a milker going longer, or stimulate maximum milk production. If other foods are supplementary to human beings because they can digest and change their food into good foods for us—milk and meat—then your arteries.

There's a historical reason for this attitude. During the 1950s there was so much more grain being harvested than there was a market for it, that there was talk even of throwing grain in the ocean to get rid of it. But then certain cowmen bought that cheap grain. They built feedlots and there finished calves cheaper and faster on that grain than they could have otherwise. And the feedlot operators got a meat-grading system put through that favored their product over the grass rancher's beef product. The grain farmers backed that new grading system, too, because it in effect legislated a couple of hundred extra pounds of grain into every cow destined for the supermarket. Thus feedlots and grain for cows got written into the law of the land: marbled beef. Forty years later, it's still there. Through advertising, "choice" beef became commonly accepted as the best beef, and more than 1 generation of people who must eat out of supermarkets have never seen anything else.

Woody Bernard says: "The meat grading system has been changed to reduce the fat in beef. Also, the more exotic breeds don't marble like the old ones."

No. 7: Feedlots feed animals beyond their normal growth into forced obesity.

True. The feedlot operator buys calves either directly from the cow-calf operation or from the middleman. He keeps the animals confined to a small area called a "feedlot" and gives them a grain-based, rather than a grass-based diet. He wants to put more weight on them as fast as possible and get them up to profitable size and an acceptably fat grade of beef. The animals are in the feedlot from 2 to 6 months. Then the feedlot operator takes them back to the auction ring where this time they are sold to the meat packer. Some feedlots use the cow manure from the feedlot to feed pigs in an associated swine-growing operation, because the pigs can get food value from the surplus grain that is passed through the cows' system. If the cows were fed only up to a normal growth, the feedlot could be viewed, I suppose, as a space-efficient, work-efficient operation for growing meat so long as the grain is cheap and available. But I see 3 big problems with them: stress for the animals; feeding of antibiotics; and overfeeding to create marbled meat.

No. 8: The USDA meat-grading system protects consumer health.

False. The USDA meat-grading system protects the grain growers who want the feedlot operator's business, and it protects the feedlot owners. It's the big reason feedlots exist, the big reason why supermarket beef isn't good for your arteries.

The trend toward feeding cows beyond their normal growth developed largely in response to the USDA meat-grading system. Up to a certain point, the cow's body keeps its muscle and its fat separate, with the fat on the outside of the muscle. But if calories are forced upon the animal—if, as in the feedlot, physical inactivity is combined with a high-calorie diet—eventually that natural barrier is overwhelmed. Fat begins to appear inside the muscle, between the muscle strands. When this happens to beef muscle (meat), that cut of meat is called "marbled." "Marbled" beef is what the law and the supermarkets call "choice beef." But "choice" beef really isn't the best for you. A normal beef animal has red meat with no fat inside the muscle tissue. This is a good thing for humans because beef fat is high in cholesterol, higher than any other domestic meat, and we don't want to eat that cow fat. But according to the law as established in USDA grading standards, beef should be fat, and the fatter the better. The fatter an animal is, the higher its meat will be graded by the USDA inspector. So feedlots pour the grain into them to make them fat.

Therefore, there is a historical reason for this attitude. During the 1950s there was so much more grain being harvested than there was a market for it, that there was talk even of throwing grain in the ocean to get rid of it. But then certain cowmen bought that cheap grain. They built feedlots and there finished calves cheaper and faster on that grain than they could have otherwise. And the feedlot operators got a meat-grading system put through that favored their product over the grass rancher's beef product. The grain farmers backed that new grading system, too, because it in effect legislated a couple of hundred extra pounds of grain into every cow destined for the supermarket. Thus feedlots and grain for cows got written into the law of the land: marbled beef. Forty years later, it's still there. Through advertising, "choice" beef became commonly accepted as the best beef, and more than 1 generation of people who must eat out of supermarkets have never seen anything else.

Woody Bernard says: "The meat grading system has been changed to reduce the fat in beef. Also, the more exotic breeds don't marble like the old ones."

No. 9: Feedlot operators feed antibiotics daily.

True. To compensate for the crowding and stress, and because of its growth-enhancing effect, feedlot operators routinely feed low-level antibiotics as part of the cows' daily ration.
No. 10: Beef from commercial slaughter houses is always safe to eat.

Not that simple. Usually it is, but not necessarily. Under the Reagan administration, slaughter houses were deregulated. Now a big operation that once was limited to processing 60 cows an hour may be processing 300 cows an hour. At that pace, it’s easy for accidents to occur. E. coli naturally occurs in the intestines of all animals. If that animal/ cow is butchered and the contents of her intestines accidentally get on the meat, the meat will be contaminated.

NOTE: It’s important, whether in home or commercial butchering, that the contents of the intestine never get on the meat.

If a batch of contaminated meat is mixed in a big vat with the hamburger from many different cows, the problem spreads. That’s how hamburger for fast food places is prepared—and how it can become contaminated.

NOTE: Always look and make sure your restaurant hamburger is well-cooked, not pink inside, before eating it. If it’s pink, send it back to finish cooking.

No. 11: Cows give off methane gas that contributes to the greenhouse effect.

True, but it’s ridiculous to take that source of methane seriously. Other related animal species contribute to the problem, too. But the big reason this particular greenhouse gas is pouring into the atmosphere in unnaturally great amounts is the use of natural gas. Natural gas is mined from “wells” and then piped into homes and industries to burn. Some of the gas inevitably leaks out of pipes into the atmosphere. In fact, it’s people who make most of the gases that cause most of the greenhouse effect. I cannot comprehend this ranting against cows. What a convenient scapegoat. They contribute only a tiny percentage—far, far less than what the once-mighty herds of 60-100 million buffalo did. It would do far more good to reduce the numbers and improve the exhaust systems of cars, ban fossil fuel burning of all sorts, and restrict belching industrial plants. Those are the biggest source of greenhouse gases.

No. 12: Cows drink a lot of water.

True, but not as much as humans use. People use (waste?) on the average 77 gal. per day per person. The drinkingest cows, of course, are lactating dairy animals of the largest breeds. They produce as much as 14 gal. milk per day for human use. They drink as much as 30 gal. water per day. The more milk they produce, the more water they must drink. Beef cows drink much less. An average 400-700-lb. steer (a typical size growing for the meat market) drinks 5–10 gal. per day. And cows, if uncrowded and on natural pasture, recycle their water back into the ground as nutrient-rich urine, which help grows their feed. People waste theirs into sewer systems.

No. 13: Cows destroy salmon spawning habitat.

Again, a joke. You try swimming from the ocean up any river and see what happens: industrial and urban pollution running into the water, dams and more dams, development up to the water’s edge. And somebody is begrudging a cow drinking at the streamside? The cow, being closely related to the buffalo or elk or moose, is the most natural part of the equation. If there were only cows living in the United States, the salmon would be doing fine.

I can’t help but wonder if there isn’t some deep human need to identify and pick on a minority and persecute it. All varieties of human beings now being off limits for preju-

dice, the homely bovine tribe and their keepers are being subjected to these arguments for extermination.

No. 14: Nobody will buy cattle that have been only grass-fed and raised without growth stimulants or antibiotics in regular feed at the price it would cost to raise them.

False. You’d be surprised how many people who can’t grow their own are desperately looking for just such meat, from every kind of meat animal! Now you can at least get leaner hamburger everywhere. And in organic-type food stores you can get “grass-fed beef.” What is grass-fed beef? It is a normal animal that hasn’t crowned his preslaughter experience by standing in a feedlot being inactive and getting obese. When a grass-fed cow goes to regular market, he is the same age as the corresponding “finished” or grain-fed cow—18–20 months, up to 24 months. And no 18–20-month-old cow is going to be tough, grain or no grain—don’t let anybody kid you about that! Grass-fed meat is what the country people who raise their own call for beef have usually eaten, tender and delicious.

You can either advertise privately and take orders for your meat, or market it through the kind of co-op that’s always looking for organic food for their customers. Here are some sources of grass-fed beef:

Colman Natural Beef: 800-442-8666; 5140 Race Court, Unit 4, Denver, CO 80216; www.colemannatural.com.

Cordonnier Meats are free-range, homegrown, corn-fed, but no drugs. They sell freezer beef (half, quarter, or by the steak); beef summer sausage; their own canned beef, chicken, turkey, and pork; chicken fryers, roasters, and farm-fresh eggs; vegetables and fruits: 937-295-2297; 3333 Russia-Houston Rd, Russia, OH 45363-9736; BertCordonnier@yahoo.com.

Homestead Healthy Foods: 830-997-2508; Rt. 2, Box 184-A, Fredericksburg, TX 78624.

Kay’s HomeFarm Beef is tender and lean, raised without using synthetic hormones, maintenance antibiotics, or processed feeds. 262-377-7292; fax 262-377-5002; R0707 Kaehler’s Mill Rd., Cedarburg, WI 53012; slc@execpc.com; myexecpc.com/~slc/HomeFarm.html.

Lasater Grasslands Beef offers cattle that are finished on grass, never confined in feedlots and fed grain, no growth hormones, no antibiotics, no pesticide treatments: 719-541-2855; PO Box 38, Matheson, CO 80830; www.lasatergrasslandsbeef.com/

Tom and Martha Mewbourne sell pasture-raised Angus at Thomrntree Farms, 276-479-3057; Rt. 2, Box 776A, Nicklesville, VA 24271.

Rob and Alanna Reed offer all grass-fed Angus and Angus-crosses at Overlook Farm; 724-756-0540; 233 Spruce Rd., Karns City, PA 16041; www.greatbeef.com.

The bottom line is that real change for the better has to be market-driven—people who spend the dollars for food have to demand and pay for organically grown vegetables and fruit and grass-fed beef. Then ag chemicals and cows supposedly fed too much grain won’t be a problem anymore!
ABOUT MILKING
A Review of Dairy Sex

You can't just buy an animal, walk out to the field, and milk it. Milk comes only from female mammals that have recently given birth and have either been continuously milked or nursed since then by their young or some other species. (For example, you can put bums lambs or a calf on a goat.) So for a cow to be a milking cow, there has to have been a bull in her life about 285 days ago—likewise with a goat, 5 months ago. Even if you buy an animal that is already "fresh" (milking), time is going to run out on you. You can't just keep milking her forever. She will gradually dry up. You have to again give the cow access to the bull or the artificial inseminator at a time when she is receptive (in heat). (You probably knew most of that, but I'm trying to assume nothing. I've had people ask me if they should pasteurize the eggs, or why their chickens won't sleep in the nests but keep climbing up to the hen house rafters, or if a heifer and a Hereford are the same thing.)

Then she has a gestation (pregnancy) of 9 months, calves, and comes fresh (gives milk). Your cow is milking again, but you also have a hungry calf. A cow usually has plenty of milk for everybody, though if it's her first calf she won't be giving as much as she will after subsequent calvings. You can separate the calf from the cow, do all the milking yourself, and feed the calf its share out of a bucket, then turn the cow in with the calf until your family runs out of milk again. Or you can keep the calf shut away from the cow all night, milk in the morning, and then let them run together the rest of the day—meaning there will be no evening milking for you.

How to Milk

When you milk an animal, you're getting into her emotional life. You can't help it, so adjust gracefully. If she's upset about anything, if something scared her, if she doesn't know you or doesn't like you yet, she won't have the contractions that bring her milk down. If in the midst of milking something scares her, or if she has a sore teat and it hurts when squeezed, the milk may momentarily stop coming down.

EQUIPMENT: It's best to milk your dairy animal in an outbuilding, or in a part of one—a place that is special for milking and cleaner than where she sleeps.

Stanchion. If yours is a gentle, experienced animal, you can tie her up to milk her (have a halter on her) or even eventually you could walk up to her in the field and milk her as she stands. I've done it. But usually a stanchion works best. A stanchion is a frame that holds a goat or cow firmly by its neck while it's being milked. Stanchions always have a manger or platform for a bowl in front so the animal can eat a treat while you're milking. (Give and you'll be given unto.)

You can fashion a goat stanchion out of one made for a cow just by nailing a board on it to narrow its grip. There is a manger where the animal's head will be, in which to place grain or hay. The animal sticks its head in to feed in the manger. Then the movable slat is moved over at her neck and fastened so she cannot pull her big head back through until allowed to. Some animals just hate stanchions and will let down their milk better if you milk them in the open. But if you're milking a big herd or have nervous animals, a stanchion really helps.

Stool. A stool for you to sit on is needed to milk a big cow. A sturdy stool about a foot high will suit you and you can milk into a bucket—one with a bail (handle) for easy carrying.

Goat-Milking Platform. Goats are built nearer the ground, so some people have little goat stanchions (or a place to tie her) built on a special raised platform about 12-18 inches above the ground. It has a little manger up front or maybe just a place for you to set a low-sided can with her treat in it. Then you can comfortably sit on a stool, which may or may not be built onto the goat's platform. If your barn floor is nice and clean, you can just sit on the floor to milk. Or you could squat to milk the goat. But it's nicest and cleanest to sit on an extended side of her platform made for that purpose.

SCHEDULING: Milking is done every 12 hours. It works well to milk early in the morning, before the animals scatter to feed. Twelve hours later you'll milk early in the evening; in winter you'll still have some daylight to do it. Either that or you need to carry a lantern to the barn or have electricity in there. If you milk a very heavy producer 3 times a day, you may get even more milk if you need it. Milking is usually done all by hand, but some.
people raising a calf or goats leave baby and mother together all night. Then you can separate them in the morning and milk for the household supply in the evening. Or separate them in the evening, and then the morning milk is for the house.

NOTE: If you're late milking, the animal's udder hurts her severely. You lose production and increase her risk of mastitis.

**Step-by-Step Preparations for Milking:** First you call your milker to where you want to meet and accomplish this. You put her in the stanchion, offer a treat to eat, groom as needed, wash her udder and teats, and then commence seriously milking, from let-down, to stripping, to her release from the stanchion.

**Calling.** A good milk cow is a gentle creature. After a while she'll come when she sees you or knows that you want her. Once she has decided to adopt you, she'll call out and run to you when you call her. You're her baby and she's going to sustain you. Have a can of grain handy. She'll follow you to the barn.

**Putting Her in the Stanchion.** You have to start by getting your milker in a situation where you know she'll stand still and where you can comfortably work at her teats for 10 or 15 minutes. You could tie her up or have somebody hold her, but a stanchion is best of all for this. She'll soon learn to come voluntarily, even eagerly, when you call and stick her head right in there if you scatter some grain or other treat in the stanchion feeder area. (Don't expect her to eat all her feed in the 10 minutes you're milking. Her regular feeder will be elsewhere.) Once her head is in place, you close the stanchion so she can't back out again.

**Grooming.** I'll confess I looked 'em over for problems, but I never groomed a dairy animal. If you're a groomer, then maybe once a day—before 1 of the 2 milkings is a good time—brush to remove dry skin, loose hair, and parasites. Dynah Geissal says they love it.

**Washing.** Wash and dry your hands before milking. Take a pot of quite warm (120–130°F) water and fuzzy rag to the barn with you when you go out to milk, so you can wash her udder and teats. You may get more milk if you wash the udder and teats, and if she's been lying in the mud it keeps the dirt out of the milk. Debris in the milk means a high bacteria count—which means it sours quicker and is likely to get an off-taste. An udder that hasn't been washed isn't as easy to grip as a damp one either. And mud that got into the milk, even just dust, will go right through your strain cloth. You'll discover it as a sort of dark sediment at the bottom of your milk jar after it has set 12 hours or more. Woody Bernard, the Dairy Agent for Pierce, King, and Grays Harbor counties in Washington, reviewed this chapter and gave me much excellent advice for which I'm very grateful. He adds here: "Washing stimulates let-down. Wait 1 minute after washing." Then milk.

**Let-Down Contraction.** Each teat is like a syringe bulb, and the bulbs are empty when the milk is held up high as it is before the let-down. No matter how you squeeze, none will come out. Your stimulation of the teat (pronounced "tit") causes a contraction reaction called "let-down" to occur in the milk-storing area of her bag. This let-down is an involuntary response under both hormonal and nervous system control. That's why when you first handle the teats of a nervous goat maybe nothing happens. It helps if you keep harking dogs and romping, noisy children away at milking time. And that's why some dairy farmers play sweet, soothing music to their ladies. If your animal is happy and relaxed, and expects to give her milk to you anyway, as soon as you handle her teats the upper part of the udder contracts and forces milk steadily down. Then when you squeeze the teat, something comes out.

**First Squirts.** The teat ends are a hole into her body, and the first milk right there tends to be higher in bacteria. So dairy sanitarians urge us not to use the first 2 or 3 squirts from each teat. Just milk them onto the ground or better yet into a cup for examination for mastitis signs (later discard). The strip cup is a neat little invention: a cup with a screen on top that really makes the strings or flakes or lumps of mastitis milk show up clearly. (You can make a homemade strip cup by putting a small tea-strainer over a cup.)

**Milking—The Main Act:** This milking can be done by machine or by hand.

**Milking Machine.** Both goats and cows can be machine-milked. Managers of huge dairies appreciate them. You can buy milking machines from a dairy supply house. But with a few animals being milked for home use, a milking machine is as impractical and unreal as a 200-gal. bulk cooling tank would be. The machine is expensive and has to be washed after each use. You can hand-milk a goat as fast as you can machine-milk, and it's simpler and far, far quicker when you include milking machine wash time.

**Hand-Milking.** Now you've got to milk for all you're worth. The contraction reflexes in the bag won't go on forever, and you've got to get the milk out while it is on. Empty the filled cavity of the teat by squeezing the milk in there out the hole in the end. Then open your hand long enough to let it fill up again from the pressure above, and squeeze it out again. On one of my goats it took about 167 squeezes on each side plus stripping to get all the milk out. In effect, you block off the space above the teat with your fingers so it doesn't go back up, and then squeeze on the rest of it to empty it out the hole. Then open up at the top again to let more milk down. Once you get going, you can really move the milk out if the hole is big enough. The reactions on each side are separate. After you've milked a teat, you might still have to work a little to get the next one going.

**Grab high on teat near udder**

**Constrict top of teat**

**Apply gentle pressure with remaining fingers forcing milk down and out**
**Squeezing Technique.** A cow has 4 teats whereas a goat has 2. Just how you squeeze the milk out of them depends on the shape of the teats. A yearling goat with very small short teats is hard to milk and it takes a long time—even though she doesn’t give much. You milk those short teats by blocking off with your thumb and index finger and then adding your next 2 fingers (one at a time) to force the milk out on out. Or you can “strip” by starting at the top of the nipple and pulling your hand down to force it between your thumb and forefinger. This will also help to enlarge a small nipple.

You have to keep your hand above or away from the nipple hole or the milk will go everywhere but the bucket. On a good-sized teat you can use your whole hand, and then it’s easy. Just block with your thumb and index finger as high on the nipple as you can get, and then add your other fingers one at a time to force the milk out gradually.

**NOTE:** Don’t grab hold above the teat on the udder tissue because that’s not natural to her, and it can harm the udder attachment and milk-producing tissue inside.

Within a few days you can be pretty fast and comfortable with it, though at first your wrists will get tired. My son Danny could milk a goat when he was 4. He fired both barrels at once. Then sat and waited for them to refill. But the usual way is to alternate hands, squeezing with one while the other is filling with new milk. So while your left hand is blocking off at the top and then squeezing, your right hand is relaxing. Then your left hand is relaxing while your right hand is blocking off at the top and then squeezing. Try to develop a smooth rhythm. Speed will come later. Eventually it should take only about 10 minutes total to milk a goat.

**Stripping.** Dynah Geissal wrote: “Butt” the udder gently with your hands several times (light slaps), especially when the milk flow slows, to encourage complete let-down.” Woody Bernard writes: “I disagree. Gentle massage is better.”

Before milking, her bag and teats will look full and round. As you milk, the teats get a wrinkled, shriveled appearance and a cow’s udder develops 2 big folds on the backside. When the flow of milk slows very perceptibly and the teat takes longer and longer to fill, it’s time to switch to a stripping motion. Use your thumb and index finger and pull them down over the teat so the teat is pulled through your fingers from top to bottom, and you have the last few drops. (Some owners support a goat’s udder with one hand while stripping with the other to avoid unnecessary downpull on it.) Strip each teat about 5 times. When one teat seems to be empty move on with that hand to another. Then go back a couple of times before you finish stripping again to get what’s left. If you get every last bit you’ll keep her milking to the max. If you leave some milk in, she’ll produce that much less next time and may never come back up to that earlier level.

**Finishing Up.** When you’re done, open the stanchion. Pat her and say a kind word like, “Thanks, old bag,” and then chase her out of the barn. She’ll be feeling a lot more comfortable with the tension off her bag since you emptied it. If you’ve ever nursed a baby, you understand how she feels. A full mammary gland (breast on you, udder on her) is misery. One that’s overfull is hell. She was desperate to be milked to relieve the discomfort.

**Barnkeeping.** Milking stimulates contractions of other parts. Be prepared when your cow spreads her legs and starts to squat, and get yourself and the milk bucket clear away fast, because it tends to splash all over. Goats are so much nicer that way. At regular intervals, like every few days, shovel the scrapings out of the barn into a pile to age and ripen for the garden. It makes the barn nice to scatter straw on the barn floor after you have it shoveled out.

**Milking Problems and Problem Milkers**

Phyllis Vallette, missionary in Djibo, Burkina Faso, wrote me: “At our semi-desert latitude, the Africans manage their cattle and goats with absolutely no barns, and very limited use of pens. The Fulanis here do make a calf-pen, which they use at milking time—they corral the calves, then a child is posted to let them out one at a time on call. The calf starts to nurse, then the milker-woman takes it off the udder and ties its neck to the cow’s front leg (both an anchor and a distraction to keep her occupied). She squats, no stool, and milks into a wooden bowl, then lets the calf free to finish off—and calls for the next calf. If a cow is likely to goggle, a second person holds the head with a long stick and loop around the horns. Goats are milked by taking a hind leg and tucking it into the crook of your knee as you squat! The Fulanis keep the kids around the house and yard all day while the adults are sent off to the bush (without a goatherd, usually) to browse. They cut small branches of leaves to bring to the kids as necessary. About 5 pm the goats return, and the air is filled with the high and low bleats of the kids and goats as they reunite. The Mauritians keep all the kids and goats together, but they fashion a little bag for the udder and tie it over the back when they want to limit the kids’ nursing!”

**Changing a Milking Schedule:** If you bought a cow that is used to being milked at 6 am and you sleep until 9 am, that’s okay. Milk her 15 minutes to a half hour later each morning and evening until you get her on the schedule you want to keep. That way you minimize the drying-up tendency. And give her lots of grain in the meantime to help keep up the milk production.

**Milk Production Factors:** Lots of things can affect her milk production. If she is standing out in a cold rain with no shelter, not only might she get pneumonia but her milk production will go down. Goats must have shelter available. If she isn’t getting a variety of good food—ample brushy range and a little grain supplement in summer, hay, grain, and vegetables in winter—her milk production will
go down. She's a wonderful conversion machine. Grass goes in one end and meat, milk, and garden manure come out at various other points, but if you don't supply her with adequate raw materials, she can't do her thing.

The biggest effect on her production is reliable, by-the-clock milking. Her ability to give milk is a long-term investment, and if you skip a milking she starts to dry up—to say nothing of her suffering and pain. If you don't milk her regularly, or if you don't milk her completely dry each milking, you trigger partial drying up. Nature makes automatic adjustments for the "baby's" demands. If you milk your cow completely dry regularly (twice a day), Nature says to that udder that her baby is growing and hungry—she's eating all you have and wants more, so keep making that much, and more if you can. So she produces as much milk as she possibly can. On the other hand, if milk is left in the udder, Nature says to her the baby is eating other food and isn't so possibly can. On the other hand, if milk is left in the udder, Nature says to her the baby is eating other food and isn't so hungry now: make less milk. So the next day she produces less milk.

**Teat and Udder Size.** The speed with which you can milk a goat is—other factors being equal (her state of mind and the quantity of milk)—probably directly proportionate to the size, both length and width, of her teat. It takes a long time to milk a yearling or a goat that hasn't been hand-milked before because her teats aren't enlarged. A good family milker isn't a natural thing. Her udder is abnormally large to cope with saving all that milk for 12 hours when nature meant her to feed her calf or kid much more frequently. Her teats are long and large from hours of being pulled on during hand-milking. So when you see a goat with a big udder and big long teats, she's probably be a good family milk goat. One reason she's so expensive is because she didn't get like that overnight.

**Extra Teats.** A 3-teated goat—with 1 normal side and the other with 2 nipples instead of 1—isn't uncommon. Nor is a 4-teater with 2 nipples on each side. You can use them just for brood goats. That means you let them rear kids and don't try to milk them, or you can try to make them into a family milk goat anyway. The third nipple may or may not release milk. If it does, you may have to develop a special way of milking that double-teat to compensate for the problem of 2 nozzles. I had one that 1 milked from behind, between her legs, because somehow when I grabbed her from that angle I had more luck getting both squirts in the bucket. I wouldn't use the son of such a goat for a breeding billy for fear the trait could be passed on through him.

**Nervous Milkers.** Nerves can really affect the amount of milk she gives you. You may get some, but not as much as you'd expect. Feel her udder. You can tell if it's still round and not slack as it should be when emptied. Try milking into food-grade plastic because it is less noisy. Keep everything routine and keep children and strangers away from her, especially at milking time. If other animals are harassing her, isolate her. Speak softly to her, if at all, and be patient. An animal gives milk when a brain signal results in the release of the hormone oxytocin into their system. (Same as humans.)

**How to Turn On a Reluctant Milker.** Sharon Koskela, Troy, MT, wrote me: "Did you ever have a problem cow that no matter what you do, she just won't let her milk down? We have to inject her with oxytocin every milking—that means no breeding back until she's off that. We've tried milking 4 times a day, bag balm, and hot packs, massage, etc., all to no avail. Just wonder if you have any suggestions. Sure could use some!!"

A cow that gets a shot of oxytocin to turn her on is going to be less likely to have a normal let-down because the injection has become the let-down stimulus instead of the normal routine of udder washing, gentle massage, and squeezing (sucking). The oxytocin should never have been started.

So how do you turn on a goat or cow that doesn't want to be milked? The answer is: You seduce her. Do a good job with your warm water and cloth washing of her udder and teats. The combination of warmth, wetness, and manipulation (like the baby that would naturally push on her udder) goes a long way toward overcoming hostility and nervousness. If that didn't work—you're still squeezing and nothing is coming out and you're afraid she's going to dry up—I know an absolutely surefire way to get her to relax and let that milk down. Maybe she's upset because she's new in your family, or has just been separated from an old buddy, or because you just knocked her kids in the head and she heard them cry out.

Just take the teat in your own mouth and suck a little. She can't resist that—it's too real. Nature will get her and the milk will come. Once the bag contraction is started, you'll have no need to resort to that again. If you'd rather find some more artificial technique, use a syringe from a snakebite kit, and it will have somewhat the same effect. So as soon as you taste the milk coming or can tell it's started, just go ahead and finish the regular way.

But some cows never get easy to milk. You have to squeeze hard and work hard for each stream of milk instead of having a good let-down contraction helping you. She's called a "hard milker" and should be sold off or eaten up and replaced.

**Switching a Goat with an Older Kid to Hand-Milking.** If somebody sells you a doe with a kid 6 weeks old and keeps the kid, you are going to have a very hard time switching her over to hand-milking. It's much better to plan ahead and do it all one way or the other. The doe with kid at side probably gets milked out a minimum of 8 times a day. By the time the kid is 6 weeks old she is producing a lot of milk, but she never has very much in her udder at any one time. Her teats are short and small because that works fine for the kid. He sucks it out instead of manipulating it out
the way we have to. If you try suddenly to milk her every 12 hours, she's almost certain to abscess on you or at least be terribly sore and miserable. Her udder isn't used to holding all that milk that long. By the time you're ready to milk, she'll be so tight and sore her teats will be hard as rock, and she'll jump and tremble every time you touch her. By the time you've tried to milk out a half gallon, 10 cc at a time, she'll be bruised—and have a very bad attitude. If it has to be done, phase her over gradually by milking rather frequently at first and then making it less and less often all the time. It's a good idea to plan on milking 1 or 2 new nans every year, along with the rest of your herd. It takes about 6 months to get them well broken in. Then let them conceive and kid again, and you'll have a good milk goat.

**Yearling Milkers.** Dynah Geissal says: "Some does start off slowly, and for the health of the [not yet full-grown] goat, I think this may be best. A yearling milker may give only ½ gal. and ½ gal. a year later. That’s O.K. She’ll come around later. The best doe I’ve ever had produced a stillborn kid her first pregnancy. I tried milking her, but her teats were half the size of my little finger and her milk supply was meager. I kept her because her mother had been a fantastic milker and this doeling had excellent conformation. Her second pregnancy produced live kids and a decent supply of milk. Also her teats had grown to small but manageable size. Her third lactation was excellent and her fourth incredible. She’s eleven now, only producing one (healthy) kid a year, but producing milk in excellent quantities for 10 months a year. From ages 4 through 8 her production was phenomenal. You can coax a young goat into producing huge quantities of milk by feeding lots of grain, but it makes no sense financially and is probably harmful to her health."

**Training an Inexperienced Milker.** It helps if, even before the first birthing, you teach the animal to enter the stanchion to get a treat in her manger and then shut her in there and handle her for a bit. Put her through the grooming and udder-washing routine. Gently touch her udder and teats enough to help her get used to the idea of it. Goats soon learn to jump up on the milking stand. All animals learn to put their heads through the stanchion opening without a struggle. Once their bags are filling with milk they learn that going to the stanchion spells R-E-L-I-E-F from the pressure plus a food treat—and so meet you there happily.

**How to Dry Her Up.** Usually your milker will gradually dry herself up, but some generous animals will go on and on until you make them stop. If you want annual kidding, then you dry her up after 10 months of milking. But you don't have to. You could continue milking her until she dries herself up. My friend Imogene has milked goats as long as 3 years without a new freshening (kidding). (So she only needed to get them bred every 2 or 3 years.) But if you do choose to dry her up . . .

**NOTE:** It's important to dry up your animal gradually and correctly to avoid udder damage and unnecessary suffering for her. (As somebody who nursed 7 babies and stopped dead out of severalnings due to ignorance and reasons beyond my control, I have personal experience and strong feelings about this!)

The way you dry up an animal is to stop milking her all the way out. For her to stop producing milk, you have to leave enough milk in there that there's some pressure. Heavy milkers are harder to dry up. The secret is to allow enough pressure to slow her up more and more without causing so much that she is in pain and her udder bruised, even infected. You (1) stop feeding grain or rich supplements. (2) Temporarily reduce water drinking (don't eliminate it completely). (3) Don't take all the milk as you milk twice a day. Then (4) milk less and less often, dropping to a once-a-day milking for a week, then to every other day, then to every few days, then once more after a week, and that should do it. (5) Watch her carefully for signs of mastitis; this is a high-risk time for that.

**NOTE:** If you want to give a worming or a lice treatment, her dry time, when there's no risk of poisons getting into the milk, is the best time to do it.

---

**Possible Reasons for Off-Flavors in Milk**

1. Did you use something other than seamless stainless steel, food-grade plastic, or glass to milk into, strain into, or store milk in?
2. Was there exposure to sunlight or fluorescent light? That causes oxidation and off-flavor.
3. Is the drinking water for your milker extra high in iron or copper?
4. Did you add warm milk to chilled milk or let chilled milk turn warm?
5. Is it late in your milker's lactation?
6. Did you feed onions, garlic, cabbage, turnip, or other strong-flavored vegetables or silage closer than 7 hours to milking time? Most of those foods work fine to feed if given right after a milking. But don't ever feed onions or garlic!
7. Are there other strong-tasting weeds in your animal's pasture that she's eating?
8. Did the doe smell strong odors within the few hours before milking, such as from a buck? Or was the buck near the milk?
9. Are you milking in a dirty, manure-filled, ammonia-reeking barn? (The milking place is best separated from more fragrant parts of your barn by doors.)
10. Did any manure, dirt, or hair get into the milk? (It helps to brush your milker before you milk.)
11. Did you wash your hands and her udder and teats, then dry them, before you started milking?
12. Are you smoking around the milk?
13. Do you daily wash milk containers with homemade soap, then rinse with boiling water? Do you boil your straining cheesecloths in water with a little lye before reusing, or else dry them at high heat in a dryer?
14. Are you getting your milk cooled to 40°F or less within an hour after milking and then keeping it cool?
15. Did you serve the milk within 24 hours?
16. Is there something wrong with your milker's health?
To dry up a cow, if she is milking more than 2½ qt. per milking, start gradually taking less about 3 months before her due date for calving. Time it so that you stop milking completely by 8 or even just 6 weeks before she is due to calve.

**Culling.** I used to be more forgiving, but Dynah Geissal says: "Don't even consider keeping a kid from any but your best does. It is vital to cull ruthlessly and to not be sentimental. Be sure to check for extra teats on any kid you are considering keeping. I wouldn't keep any mature doe (or her kid) who didn't provide at least ½ gal. milk per milking throughout spring and early summer. Near breeding season, production will drop, but there should be a reasonable amount, gradually tapering to about a quart 2 months before kidding."

**Coping with Bad Attitudes and Bad Habits:**

If your cow or goat puts her manure-caked foot right in the middle of your milk bucket just as you are finishing milking her, don't kill her. You aren't the first one it ever happened to.

**Kicking.** You might think the front end is so far away it couldn't know what the hind end is doing, but a mad cow can kick with hind foot forward, to the side, or back, and she can put that foot right where she aims it; it can really hurt. Some of them really make a habit of it. In that case you'll have to develop a defense. If she does succeed, just consign any contaminated portion of the milk to the animal's milk-producing capacity (any lactating female can get it, women also), which is threat enough. I've seen animals near death because it went into a general systemic blood poisoning.

**Bodily Restraint.** If she kicks or is otherwise hard to control, you'll have to milk in a stanchion for sure. In the case of a goat you can hold 1 foot while you're milking with the other hand. For a cow, use hobbles on the hind legs of any animal that kicks the bucket or dances around. There are various styles of them. Lane Morgan says, "Another thing we've done with a kicky cow is to have one person hold her tail up while the other one milks. You have to grab it right at the base or you risk injuring the tail. Cows can't kick with their tails held straight up—I don't know why but it's true! After a few days—with luck and kindness—the cow calms down and forgets about kicking."

Some goats kneel on their front feet when you try to milk them. Some have the habit of trying to lie down completely. In the former case you can learn to milk her on her knees. In the latter, you can either rig up a body sling or make hamburger out of her. Part of breaking her of any bad habit is to refuse to stop milking—even if you have to milk on the ground. Then she may give up resistance as ineffectual.

**Tails of Woe.** One thing that a cow can do to you that a goat can't is switch you right in the eye with a manure-caked tail. If she's got that habit just include her tail in the middle of your milk bucket just as you are finishing milk-
(a cow's udder has 4 separate quarters, each with its own faucet-teat). If you can catch it while it is confined to one quarter you can prevent it spreading to the others.

**Cure.** Mastitis is very hard to cure even using antibiotics, which are about the only hope you have. For a suspected case, the vet can test a milk sample. Daily shots of antibiotic give me the best results. Check with your vet by telephone for the kind and amount. **Knock out the infection as quickly as possible before the animal's current and future milk production is jeopardized. Get on it the day you detect or suspect mastitis, and stay on it until it's gone.** Your animal will more than likely have dried herself up a lot before it's over though. Rich feed may help bring her back if she's recently fresh. If she is severely abscessed, you'll have to dry her up, and she'll have a tendency to abscess again next time around. Dynah Geissal says she won't keep a goat who has it twice.

**NOTE:** Mastitis can spread from one dairy milker to another. Always milk mastitic animals last. Don't throw their milk away.

**Chapped Udder.** Rub Bag Balm on her after milking.

**Cut Teat.** Cuts occur often on the teats. Clean the cut. Don't break your milking schedule—even if it takes a long time to milk that cut teat, and the cow suffers, and you agonize in sympathy. She'd suffer more if the milk built up, swelling in that teat under the cut and abscessing above it. You may have to hobble her to keep her from kicking if it hurts.

**Milk Fever.** This is a disease of pregnant or just-delivered animals. A goat with milk fever, according to Dynah Geissal, "lies down with her head turned back against her side. Other symptoms are muscle tremors, walking unsteadily, and subnormal temperature. The disease is prevented by a good daily mineral mix to maintain a proper calcium/phosphorus balance. The disease is hypocalcemia. The cure is to inject calcium gluconate and works almost miraculously."

**Tuberculosis.** Nowadays this isn't a very common dairy disease because of the long vigilance practiced by dairymen. But it's still smart to have your dairy goats and dairy cows checked for TB by a vet because the animals can get it from coming into contact with an infected wild animal. It's worth the money to be sure the milk is safe. But, according to statistics, you're far more likely to get TB from living in crowded quarters in the inner city than from a dairy animal.

### About Milk and Milk Products

#### Milk Types

**Colostrum Milk:** It's very important to get the mother's first milk into the kid, calf, etc. The general rule is that the milk for the first 4 days is for the baby. Either let the baby nurse those days at least, or milk her yourself and bottle-feed it to her baby. That milk has a special name, "colostrum," and it looks special—thicker and darker in color than regular milk. Colostrum contains precious immunizations and vitamin concentrates the mother is passing on to her kid, and the kid is likely to be sickly without it. Don't heat colostrum milk more than barely lukewarm because it will turn hard as cheese and be useless.

You have to go out within a couple hours after the goat has kidded, take the kid and put it in a warm dry place, milk the nanny mother for her colostrum, and then get her comfortably settled if you are planning to separate them. You can freeze extra colostrum milk (it's best frozen in a sterilized glass container). Then you can thaw and warm it to feed multiple births or an orphan that may appear later.

**COLOSTRUM MILK CUSTARD** The Swedes, Lane Morgan, and Kim Carlson (who helped edit this chapter) enjoy this specialty! Lane writes, "Mix 1 c. regular milk with 2 or 3 c. colostrum (second, third, or fourth milking). Add ½ c. honey or sugar and stir. Season with cinnamon and bake or cook in double boiler. The colostrum will thicken and set without eggs because it's rich in albumen. It tastes very rich." But Woody says, "The milk shouldn't be used for human consumption for 4 days after birth."

**Whole and Skim Milk:** "Whole milk" is milk in which the normal amount of cream is mixed throughout the milk by shaking it up. This is always a temporary situation with home milk, as you can't duplicate the dairy homogenization that shakes it up never to separate. If all the cream has been skimmed or separated out of the milk it is called "skimmed milk" or "skim milk." Skimmed milk is fine food for chickens, pigs, and the like.

**Sweet or Sour:** Sweet milk is fresh milk. As the days go by, especially at warmer temperatures, the bacteria do
their natural thing and your milk (or cream) turns sour. When thoroughly soured, or "clabbered," it "sets up" and separates into a thick part (curds) and a thin clear liquid (whey). You can make cottage cheese out of this or feed it to the animals. Sour milk can be achieved naturally by waiting, or hurriedly by adding 1 T. lemon juice or vinegar per cup of milk.

The old-timers didn’t feed their chickens very much, if any, grain. They fed them clabbered milk! Chickens do very well on a steady diet of this sour milk. Or you can give them fresh milk. But it’s easier for them to get at the milk protein if you clabbered it before feeding. The clabbered milk is also somewhat more digestible for them. (They need plain water in addition to the clabbered milk.)

**Changing Milks:** Goat’s milk does not taste like either raw or store-bought cow’s milk. You may have trouble changing your family over from any one kind of milk to any other. I can remember as a child how awful the store milk tasted to me when we sold our last cow and then how awful the raw milk seemed to taste for a while when several years later we again had a milk cow.

First serve the new milk in eggnogs, Postum (1/2 milk), and such. Once your family gets used to drinking it in mixtures, drinking it straight will soon follow. Give babies an especially gradual transition, starting out with one-fifth of the new type and working up gradually. There may be a period of either constipation or looseness until they make the adjustment.

**Switching Baby’s Milk.** If you try to switch a baby over without this gradual introduction, your child can end up in terrible distress. Cow’s milk is very constipating for babies who have been on canned formulas. If you try to make a sudden, total switch, your baby might not be able to have a bowel movement—even need surgery. So be gradual when you set out to change a baby’s milk type—even one you think is a “big” baby, even a toddler. Watch the subsequent bowel movements carefully. Give that one-fifth part of the new milk. Wait to see how the next few bowel movements are. Then increase the mix one-fifth more, and so on. If there’s a problem, reduce the new milk. Some children never do tolerate cow’s milk.

**Milk Handling**

You need a stainless steel or food-grade plastic container to milk into, and quart, half-gallon, or gallon jars to store milk in; Bag Balm for treating teat and udder chapping and nicks; and cheesecloth or another system to strain the milk. There are other possible items but they’re optional. Stainless steel is expensive but it lasts a lifetime.

**Cleaning Home-Use Milk Utensils:** Quick-cooling the milk and using clean utensils can vastly improve milk flavor.

1. Prerinse with lukewarm water as soon as possible after their use. Lukewarm is important because cold water forms solid, hard-to-clean-off butterfat, and hot water coagulates milk protein and makes it stick to things.
2. Wash with an alkaline soap: 1 T. washing soda dissolved per quart of water, or homemade soap, or "dairy detergent." Do not use regular detergent.
3. A scrub brush helps.
4. Then rinse.
5. Give a final scald with boiling-hot water.
6. Air dry on a rack upside down because if you wipe them with a cloth, you’re just rubbing bacteria back onto them.
7. Before you take your milk bucket out in the morning, you could rinse it out with boiling water from your tea kettle.

**Straining the Milk:** You’ll have less to strain out if the udder is washed before milking—or at least wiped off to get rid of dried mud and manure that might fall into the milk. Your next chance to prevent contamination is at the straining, when you bring the milk into your house. Straining helps to get rid of hair, dirt, and so on, which cause off-flavors and a high bacteria count. Milk with a high bacteria count will sour fast. You'll help avoid strong-tasting goat’s milk if you strain and refrigerate right after milking.

**Strainers.** A regular commercial milk strainer looks like a big metal bowl with holes in the bottom. A ring fits in the bottom to hold down a paper filter disk. The gunk is trapped on the disk, which is thrown away after the straining. For a homemade strainer, pour your freshly milked milk through 4 thicknesses of dish towel, clean diaper, or cheesecloth laid over a large strainer. This won’t catch soluble impurities. They settle as a kind of "dust" in the bottom of your jar and do no harm I know of. Or you can buy that specially designed milk strainer and use throwaway strainer pads. But there’s no throwaway involved if you strain through cloth. Rinse and boil the cloth afterwards to clean it. That’s my preferred system.

**Cream Separation:** See the section on cream. In this case you separate after straining but before bottling.

**Raw or Pasteurized?** Raw milk does not taste like pasteurized milk from the store. The more raw milk ages, the more pronounced the difference becomes. If you’re going to pasteurize, do this after straining (and separating if you choose), and before cooling.

**Pasteurizing.** Pasteurization is a germ-killing process achieved by the temperature you heat the milk to and the length of time you keep it there. The higher the temperature, the shorter the time. You can pasteurize cream, milk, or any combination thereof. There are pros and cons to this decision. If you’re selling milk, you usually are required to pasteurize. But if your animals are tested against tuberculosis and brucellosis and clear, pasteurization isn’t needed for healthy home milk and just makes more work and more stuff you have to wash for no reason. I like the taste of raw milk. The process does destroy a goat milk enzyme, which causes it to eventually develop that goaty flavor. But if you’re getting plenty of milk twice a day there’s no need to have it fresh-tasting longer. Pasteurization doesn’t hurt the
food value of milk except it decreases vitamin C and thiamin—but milk doesn’t have much of those anyway.

NOTE: Boiling milk or over-sterilization harms the nutritional value of milk.

Machine Pasteurization. If you’re doubtful about the health of your milk source (pasteurization will kill TB germs and won’t affect flavor much if done right), or just want to pasteurize anyway, the easiest route is to buy a home milk-pasteurizer, which will pasteurize up to 2 gal. milk at a time, for $225 from New England Cheesemaking Supply (413-628-3808; www.cheesemaking.com).

Flash System. Set a pan (only glass or quality stainless steel) inside another with water between them, double-boiler style—because milk burns so easily. Put the milk into the top pan, cover, and heat to 161°F. Hold at that temperature for 15–20 seconds, then cool. Don’t let the temperature get higher than 165°F, and don’t keep it up there more than 20 seconds or you risk a cooked taste. Judge the temperature using a floating dairy thermometer. (Another system is to heat the milk quickly in an open-topped container, stirring constantly with a stainless steel spoon.) Then cool the milk fast as possible by setting it in ice water or under cool running water. Stir constantly until it gets down to 60°F, then once in a while until it gets down to 50°F.

Slow System. Create a double boiler as above. Heat milk to 140–150°F and hold it at that temperature for 30 minutes. Stir once in a while with a sterile, stainless steel spoon. Cool as above.

Bottling. Pour the milk into clean, scalded, jars or bottles, and cool it. Cover with lids.

Cooling. You milk the animal, take the milk into the house, strain it, and cool it—all in quick sequence. That’s because warm milk is perfect food for bacteria, and so you want to get it cooled as fast as possible. Fast cooling avoids off-odors from bacterial growth. You can put it into prechilled quart glass jars, and put them in the coldest part of the fridge. But milk will cool even faster if it’s sitting under running cold water, or in a pan of ice water with more ice added as needed. Your basic goal is to cool it down to 40°F within 1 hour. If you pour milk into a jar that’s at room temperature and just set it in the fridge it won’t get that cool that fast. It won’t be bad to drink, but it will be more likely to develop an off-flavor if cooled too slowly. Fresh milk keeps best if stored around 34°F.

Fresh or Aged Milk? On the farm you should drink both goat’s milk and cow’s milk fresh. When you’ve got it coming every 12 hours there’s no reason to use milk over 24 hours old for plain table milk. You can use older milk for baking, cheese-making, etc.

Preserving Milk: Sometimes you will have more milk; spring and summer are peak months for milk, as well as eggs. Late winter may find you really short of milk. Cheesemaking is a way to preserve milk from your surplus times for your lean times. See the section on cheese storage for more information. The old-timers around here go out in the spring and come back with pans of mushrooms. They saute them in butter and eat them right away, can them, or make soup: Wash 1/2 lb. fresh mushrooms, bruising them lightly if necessary, but do not peel. Chop rather fine. Brown slightly in 6 T. butter. Then blend in 4 T. flour, and gradually stir in 6 c. milk. Cook in the top of a double boiler for 20 minutes, stirring frequently. Season with salt, pepper and paprika. Serve with crackers.

Cream of Fresh Mushroom Soup. The old-timers here go out in the spring and come back with pans of mushrooms. They saute them in butter and eat them right away, can them, or make soup: Wash 1/2 lb. fresh mushrooms, bruising them lightly if necessary, but do not peel. Chop rather fine. Brown slightly in 6 T. butter. Then blend in 4 T. flour, and gradually stir in 6 c. milk. Cook in the top of a double boiler for 20 minutes, stirring frequently. Season with salt, pepper and paprika. Serve with crackers.

Cream of Onion and Potato Soup. Boil about 4 c. cubed potatoes and 4 sliced onions together in water until tender. Drain, saving the water. Rub the vegetables through a coarse strainer or blend them into a puree. Melt 2 T. butter and then mix into it 2 T. flour, 1/4 t. salt, and a pinch of pepper. Gradually add 3 c. scalded milk and the potato water. Stir constantly as you add the liquids. Add the potatoes and onion puree, stir, cook 3 minutes, and serve.

Cream of Spinach Soup. Puree 1/4 c. cooked greens in a blender or chop fine or rub through a sieve. Combine 2 c. milk, 1 bay leaf, 2 sprigs parsley, and 1 t. minced onion, and heat to boiling. Melt 3 T. butter, blend in 3 T. flour, a pinch of paprika, 1 t. salt, and the milk mixture. Simmer 5 minutes, stirring constantly. Add the spinach to the mixture.
and ¼ c. cream. Reheat and serve.

**CREAM OF TOMATO SOUP** Peel about 6 tomatoes and cook, or use about 2 c. canned tomatoes. Simmer for 15 minutes after you have mashed them to break up large pieces. Now cool and then puree in a blender or just finish mashing. Add ½ t. soda, 1 T. honey, and 1 t. salt. In a separate pan melt 2 T. butter. Mash in 2 T. flour. Then gradually stir in 2 c. milk, stirring constantly until it thickens. Now stir in your tomato mixture, 2 c. more milk, and 1 T. finely chopped parsley, if you have it. Heat and serve.

**MILK BEVERAGES**

- **HOT FLAVORED MILK** Combine 1 c. or more scalding hot milk and a pour of molasses (or some instant cocoa, or a little honey and vanilla). Beat it up with the eggbeater or put into the blender. Pour into a glass. Sprinkle nutmeg on top. Serve with toasted homemade bread.

- **BANANA MILK SHAKE** Slice 2 bananas and beat until creamy, or put through a coarse sieve, or blend. Add 2 c. cold milk, mix thoroughly, and serve at once.

- **GOAT MILK SHAKE** From Sonya Lizarraga, Salome, AZ: “You just freeze the goat milk in small containers (neighbors give me their plastic cottage-cheese cartons). When you want your shake, you cover the blades in your liquifier (blender) with just cold milk, then put in 2 big spoons of carob powder (a good protein) and a banana. Then add as much frozen goat milk chunks as will make it thick, blending to mix up well. Fun to experiment with other flavors too, but banana is our favorite.”

- **REAL STRAWBERRY MILK SHAKE** Crush about 1 qt. strawberries, and press through a coarse sieve in order to get at least ½ c. puree. Or blend. Combine the strawberry puree with 5 c. milk and ½ c. cream. Add ½ c. honey, ½ t. salt, and 2½ t. lemon juice. Mix well and chill. Top each glass with a spoonful of whipped cream.

- **BANANA-STRAWBERRY SHAKE** Mash 2 medium-ripe bananas and combine with 1 c. slightly sweetened, crushed strawberries. Mix in 1 T. lemon juice, 1 qt. milk, and 1 qt. slightly softened vanilla ice cream with a whisk. You could garnish each serving with a fresh strawberry.

- **APRICOT MILK** Put 1 c. cooked apricots and their juice through a sieve, or blend. Mix the pulp with 3 c. milk. Put ½ pint vanilla ice cream in a pitcher and pour the milk mixture over it. Stir slightly.

- **PRUNE MILK** Pit and mash the prunes until you have 1 c. pulp. Add that to 3 c. chilled milk, and beat them together or shake in a jar. Pour into glasses and top with whipped cream.

- **PEAR AND GINGER ALE MILK** Press 1 c. cooked or canned pears (not the juice) through a sieve, or blend. Mix with 1 qt. milk. Pour into glasses, and to each glass add a splash of fizzy ginger ale (recipe in Chapter 5).

- **MAPLE AND GINGER ALE MILK** Add ½ c. maple syrup to 1 qt. milk, and mix well. Pour the milk into tall glasses and add ginger ale to taste.

- **MILK LASSIE** Stir 1 T. molasses into 1 c. milk, hot or cold. Easy and nice.

- **BANANA LASSIE** Mash 1 ripe banana until smooth. Stir in 1 T. molasses and a pinch of salt. Add ¼ c. milk and mix well.

- **ORANGE JUICE** Combine ½ c. frozen orange juice concentrate, ¼ c. milk, ½ c. water, ¼ c. sugar, ½ t. vanilla, and 6 ice cubes in a blender, and whir until smooth. Serve right away.

- **SHAKER SYLLABUB** The Shakers heavily sweetened 1 gal. warm apple cider with maple sugar or syrup and grated a nutmeg on top, then milked the cow right into the mixture and served it at the table while still hot and foamy. Some winter I'm going to try that just for adventure!

**CUSTARD:** Custard can be made by baking or boiling, or can be thickened with rennet, which causes a yogurt-like result. Custards have to be cooked at a low temperature and not too long or they will curdle. But frankly, I'm always in such a muddle my custards “curdle” more often than not, and they are still delicious. All “curdle” means is that some water separates out. I just pour it off and serve what's left. The best way to regulate the cooking temperature of baked custards is to surround the pan with water. Set the individual custard dishes in a pan of hot water. Make all boiled custards in the top of a double boiler. Milk that is a little sour can also cause curdling.

If the custard does start to separate, remove it immediately from the heat, set the custard pan in a pan of cold water, and beat to redistribute the particles. Any acid such as lemon juice would reinforce the tendency to curdle. Baked custards come out firmer than boiled custards. You know it is done when the blade of a knife run into the center of the custard comes out clean. The firmness of the custard is also a result of the amount of egg in it. The more egg in your custard, the firmer it will be. Two eggs per cup of liquid is a good general guide. One egg per cup of liquid makes a soft custard, all right for baking in small cups.

**BAKED CUSTARD** Combine 3 lightly beaten eggs, ½ t. salt, and ½ c. sugar. Add 3 c. scalded milk slowly, stirring constantly. Add ¼ t. vanilla. Pour into custard cups. Sprinkle with nutmeg. Place the filled custard cups in a pan of hot water and bake in a moderate oven (325°F) for 45 minutes, or until a knife inserted in the center of the custard comes out clean.

For chocolate custard: Add ½ oz. (squares) of chocolate to the milk and heat until melted. You can't use that instant chocolate stuff.

For coconut custard: Add ½ c. shredded coconut to the mixture.

For coffee custard: Scald 2 T. ground coffee with the milk, strain, and proceed as for the baked custard.

For date custard: Add ½ c. chopped dates to the custard before baking.
For honey custard: Use ½ c. honey instead of sugar.
For rum custard: Leave out the vanilla and add 2 T. rum.

BOILED CUSTARD: Combine 2 lightly beaten eggs, ¼ t. salt, and ¼ c. sugar. Add slowly 2 c. scalded milk, and cook in the top of a double boiler until the mixture coats a spoon. Add ½ t. vanilla and chill.

For almond custard: Use almond extract instead of the vanilla, and top with shaved, toasted almonds when ready to serve.

For caramel custard: Use brown sugar instead of white.
For chocolate custard: Melt 1 oz. (square) chocolate in the milk.

Custard making is so simple and yet such an art. My mother’s custards were carefully made in little individual dishes. They always came out just perfect, and were such a gift of love it makes me both hungry and homesick just to remember them.

RENNET PUDDINGS: Rennet puddings made from scratch turn out like yogurt. When Little Miss Muffet was sitting on a tuffet, eating her “curds and whey,” I figure it was a junket rennet pudding. They used “essence of pepsin” or “liquid rennet” or a “junket tablet” to make them. That’s the same rennet that is used in cheese-making. (See “Cheese” for how to make rennet if you don’t buy it.)

BASIC RENNET PUDDING: Just stir in the acid, let the milk stand at room temperature for about 20 minutes, then refrigerate. Serve with cream and sweetening, or fruit. It’s very bland.

VANILLA RENNET CUSTARD: Combine 2 c. milk, 2 T. sugar, and a dash of salt in a small pan. Cook, stirring constantly, over low heat, until lukewarm. Remove from heat, and add 1 t. vanilla. Crush 1 rennet tablet in cold water in a cup, stirring until dissolved. Add it quickly to the milk mixture, stirring only once or twice. Pour immediately into a quart dish or into individual dishes. Let stand at room temperature until the mixture is set (do not move) then chill. The custard will set in 10-30 minutes, depending on the temperature of the room. The higher the room temperature the more time is needed. Sprinkle top of custard lightly with nutmeg or cinnamon just before serving. Rennet is sometimes available at grocery stores.

FLOUR-THICKENED MILK: Mrs. Lillie R. Balph, Beaver Falls, PA, wrote me: “My mother served this to us as a breakfast cereal. It isn’t a soup. She used flour to thicken the milk to a pudding consistency. She put butter and salt in it and heated it until it was very smooth and creamy. She served it in cereal bowls. She ate it with sugar and more butter, but Father and us children used cream and sugar. My aunt made hers lumpy as did other women in the community. Sometimes I make it for myself.”

Kat Atkins, Coquille, OR, speaking of goat milk, wrote me: “I keep a quart made and in the fridge, and I add at least 2 eggs to each quart and thicken with 3 heaping T. flour. Then I just make toast and pour the milk over, after re-warming, add some nutmeg now and then and Instant Breakfast. Also great over oatmeal. Good for people with queasy stomachs. Good frozen. Makes soup and a good base liquid for any cooking. I make it ahead when I’m not busy. It lasts about 3 days. ‘Thickened milk’ made with a dash of vanilla, poured into a bowl with granola topping even pleases and fills my husband at breakfast.”

CULTURED MILKS: Store-bought buttermilk, kefir, and yogurt are the 3 common cultures in use, but they are not the only ones. For more information on these quick milk cultures, read Making Your Own Cheese and Yogurt by Max Alth (1973) (also good on cheese-making); and Yogurt, Kefir, and Other Milk Cultures or Fermented Foods and Beverages, both by Beatrice Trum Hunter. You can order the appropriate culture starters from dairy or cheese-makers’ suppliers, or start with some grocery-store product. Kefir grains and other specialized products for yogurt and kefir-making are available from GEM Cultures: 707-964-2922; 30301 Sherwood Rd., Fort Bragg, CA 95437; www.gemcultures.com. GEM also sells a culture thermometer ($7), cheesecloth, and Kombucha Tea Fungus.

CULTURED “BUTTERMILK”: Real buttermilk is the liquid left over after you’ve churned butter. It is delicious and good to use in cooking or to drink straight. Commercial dairy “buttermilk” or homemade cultured “buttermilk” never was near a butter churn. It is made by adding a culture to milk to thicken it. At the dairy, sometimes dots of melted butter are sprayed into the cultured milk to make it look “buttery” (real buttermilk doesn’t have any butter in it). They add 1 or 2 percent butter that way—whatever they think the customers want. Then the “buttermilk” is ready for sale.

So dairy-type “buttermilk” is skim milk that has been cultured with a variety of bacteria in the same way you make yogurt. It sets up (thickens) 12-14 hours after the culture is introduced. Then you stir to break up the mass. That’s why it doesn’t have a yogurt-like consistency. NOTE: To substitute in a recipe for store buttermilk, you can use your homemade yogurt plus a dab of butter.

Buttermilk-Cultured Milk: Mix 2 c. raw milk or home-grown milk with ¼ c. store buttermilk. Cover and set in a warmish place for 24 hours. (Read instructions under “Yogurt,” because it’s the same procedure.) You can use ¼ c. of your resulting thick milk to start a new batch and so on. You can make cottage cheese out of the results. Both curd and whey are good and nourishing to eat if you want. Any little mold that forms on top can simply be scraped off and given to the animals. Buttermilk culture is the least sour tasting of the three. Sourness also depends on how soon you eat it. The sooner you eat any of these 3, the less sour they will be. The longer you wait to eat your cultured milk the more sour it will be—up to a certain point. You can keep the culture going until it gets contaminated in the same way yogurt does.

YOGURT: This is milk soured by a selected variety of bacteria. Yogurt is thickened because the bacteria consumes the milk sugar and changes some of it to lactic acid. Once you have made a yogurt culture at home you can keep making more by using a little of your last culture to make each new batch, but eventually the mixture gets invaded by an off-breed of bacteria. In that case you could start over with some dairy yogurt. This happens about once a month. Once you learn to make this wonderful stuff, consider getting The Stonyfield Farm Yogurt Cookbook by Meg Cadoux Hirshberg, available from Harrowsmith (see magazine list in Chapter 1) for 300 yogurt-using recipes. Garden Way offers Cooking with Yogurt, Bulletin A-86: yogurt gravy, salad dressing, soup, frozen, etc. Electric yogurt-makers are nice but not necessary.

Getting Your Culture to Start: An easy way to get started is to buy a pint of yogurt and add 3 T. of that to a quart of...
your own milk. You can use cow, goat, or soybean milk—even powdered skim milk. Or use a commercial yogurt culture for a starter. You can’t make your own culture (starter) unless you’re a bacteriologist, because that involves isolating a batch of 1 kind of invisible bacteria from all the others and growing it alone.

**Yogurt Thickness.** The thinnest yogurt is made from non-fat dry milk liquefied with water. Mixing it with skim milk gives you a thicker yogurt. Starting with whole milk makes it thicker yet. Making the yogurt from whole milk with some nonfat milk mixed in gives you thicker yet. If you add evaporated milk, or light or heavy cream to whole milk you get the thickest yogurt of all!

**Secrets of Great Yogurt**
1. Start by pasteurizing the milk.
2. Cool milk to 105—110°F.
3. If you start from store-bought yogurt, make it an unflavored, additive-free one: 2 T. per quart of your milk.
4. Keep the mix as near 105—110°F as possible while it’s working.
5. It takes more than twice as long for yogurt from a noninstant milk powder, 8 oz. Dannon brand plain yogurt, ½ t. honey, and (optional) a dash of vanilla. Pour into 1-qt. sterile jars. Cover the top of each jar with plastic. Put a heating pad into a canning kettle (36-qt.) and turn pad on to high until the kettle is warm inside. Put a down pillow on top of pad, then the jars—wrapped in towels—then another pillow. Don’t leave air space. Change heating pad temperature to medium and wrap kettle in a blanket. Let go 3 days. Unwrap and put jars of yogurt in fridge.

**For Your Next Batch.** Save about ¼ c. of your first batch. Keep it in the refrigerator or in a covered container. Use it within 5 days to start another batch of yogurt. And so on until your yogurt gets that off-taste that shows you that some sort of bacteria has moved in on the original variety. That’s when you have to get some of the store kind again. You could also buy yogurt culture direct from a dairy supplier if you have use for so much at once.

**More Yogurt Recipes.** There are so many good things you can make from yogurt.

**FLAVORED YOGURTS** Blend in with the finished yogurt berries that have been put through a sieve or blended, or any fruit juice. Use about ½—¾ c. flavoring per 2 c. yogurt. Sweeten with honey or sharpen the flavor with lemon juice as you prefer. Rhubarb sauce and yogurt go well together. Or serve it with any whole fruit. Use it for a vegetable salad dressing combined with seasoning—parsley, horseradish, tomato juice, onion, or Roquefort cheese.

**VANILLA YOGURT** Mix ½ t. vanilla flavoring into your quart of milk that’s going to be yogurt. Sweeten to taste.

**YOGURT AND CUCUMBERS** Peel 3 large cucumbers and slice into ½-inch-thick pieces. Combine 4 c. yogurt, 1 clove garlic—ground or finely chopped—and 1 t. salt. Pour over the cucumbers and serve cold.

**YOGURT-FRUIT DRINK** In a blender combine 1 c. fruit juice, 1 c. yogurt, a little honey, if you need more sweetening, and ½ c. ice, if you want it really cold.

**BANANA-YOGURT DRINK** Combine in a blender: 1 c. yogurt, ½ c. milk, 1 banana, and honey to taste. Ice is optional.

**YOGURT SALAD DRESSING** Combine 4 cloves finely minced garlic, 4 T. lemon juice, ¼ c. cooking oil, and 4 T. grated onion with 2½ c. yogurt, 2 t. salt, ¼ c. chopped parsley, and a pinch of red paprika. Serve chilled.

**FROZEN YOGURT** Soft frozen yogurt is good topped with nuts, honey, granola, fruit, fruit juice, or any other sweetening. Mix yogurt with fruit (1 c. yogurt to 1 c. fruit). Use fresh fruit, finely cut. The procedure is to freeze your yogurt to a soft mush, then beat it up with fruit, freeze again, and serve.

**CARDAMOM FRUIT YOGURT** Mix 3 c. yogurt with 1 c. any fruit; add 1¼ t. ground cardamom.
YOGURT CHEESE  See “Yogurt Cream Cheese” in the “Cream Cheese” section.

KEFIR:  This is very similar to yogurt except it is a little different in taste, more fluid in consistency, and made a little differently. To a dairy bacteriologist, kefir is a symbiotic association of certain organisms: a gum-producing microbe that manufactures the polysaccharide grain, a lactose-fermenting yeast, and several lactose-fermenting bacteria (Lactobacillus bulgaricus, Lactobacillus acidophilus, and Lactobacillus kephiri). In plain English, it’s a variety of cultured milk, like yogurt. Yogurt is firm and eaten with a spoon, but kefir is liquid. That’s because it has very low curd tension, unlike yogurt in which the curd holds together. So you drink kefir. Kefir is a great tradition in Caucasia and the Eastern Mediterranean. It’s nourishing and healthy stuff and is supposedly more digestible than yogurt because of the smaller particles. It’s good to drink mixed with fruit juice or fresh or frozen fruit, or sweetened with honey, sorghum, or molasses.

For success make your kefir by stirring the grains (see below) into your home-grown raw milk and let stand at room temperature overnight.

EASY KEFIR  Combine 2 c. raw milk with ¼ c. unflavored store-bought kefir. Cover and let rest for 48 hours.

KEFIR MADE FROM “GRAINS”  Mrs. George O. Nordmann, Topnton, NC, wrote me this recipe for kefir: “First, obtain some kefir grains. The surplus may be dried, frozen or held over for a short period in the refrigerator. The grains may be used with any good quality milk: powdered, skim, goat’s, cow’s, or soya milk. When using powdered milk, avoid chlorinated and/or fluoridated water. Place the grains (after rinsing in cold water) in the amount of whatever kind of milk you use in a quart jar and let set at room temperature overnight. Next day, strain out grains, rinse them and place in more milk in another container. The milk from which the grains were removed is now ready to drink. The sourness depends on the length of time the grains were allowed to stand in the milk. Always rinse the grains in cold water before reusing. The proportion of grains to milk should be about 1 c. grains to 1 qt. milk. They multiply fastest in skim or low-fat milk at about 68–70°F.”

KEFIR FROM A BLOB  Alan Clute, Sunnyvale, CA, got some kefir culture from a friend. “Ours is a gelatinous blob, about ½ inch across, which we recently got from a friend. You just plunk it into some barely warm milk and let it sit, covered and wrapped, at warm room temperature—no need for special heat as with yogurt. Next day you fish it out and repeat, sort of like milking a cow. When the blob grows big enough, it can be divided and shared. Our friend said the culture needs to be used every couple of days or so, which means that, as with a cow, somebody else has to care for it while you’re away.”

KOUMISS: A popular old-time fermented milk beverage, this was originally of mare’s milk. Put milk fresh from the cow into a scalded pop or small wine bottle. Fill it almost up to the top and cork tightly. Shake it up thoroughly every day for 10 days. At the end of that time it is koumiss and ready to drink.

CHEESE  Welcome to the world of cheese-making! It’s easier than you think. In fact, cheese is simply naturally or artificially coagulated milk with the whey poured off or pressed out. The importance of cheese viewed as a traditional food is that it’s the only way to preserve milk when you have no refrigeration. Even so, this is a temperate-zone preservation system. In the tropics the temperatures are just too hot except for storing ghee (see “Butter”). Old-time dairy animals didn’t milk as many months a year as ours do now. And milk in the form of cheese tastes better—rather than worse—with the passage of time! Milk in the form of cheese, after 60 days, is guaranteed free of bad germs because the cheese-making process kills them; so where pasteurization was impossible and there were health problems with the milk, cheese was the safe way to eat it.

CHEESE NETWORKING

Online. Cheesemakers-L is a list group with a great website. It’s for serious cheesemakers and also folks with dairy animals who just want to make good homemade cheese and dairy products: members.xoom.com/cheesemaker/Cheesemakers-L.htm.

Books. When I first wrote about cheese, in 1971, I couldn’t find recipes anywhere. Now there are lots of them. The best to date are in Goats Produce Too! by Mary Jane Toth. Her recipes will usually work for either goat or cow milk. She also has recipes for goat milk soaps, chevon (goat meat), and goat milk ice creams, sherbets, and fudges. Price is $12.95 plus $2 s/h: 517-465-1982; 2833 N. Lewis Rd., Coleman, MI 48618; mj@voyager.net. New England Cheesemaking Supply (413-628-3808; www.cheesemaking.com) published The Making of Farmstead Goat Cheeses by Jean-Claude Lejaouen, an expert on French sheep and goat cheeses (70+ goat-cheese recipes, and how to build a cheese room); and a beginner’s text, Cheesemaking Made Easy, by Ricki and Robert Carroll (60 cheese recipes for both goat and cow milks). Goat Cheese: Small-Scale Production, by the Mont-Laurier Benedictine Nuns, covers making mold-ripened cheeses. Older books are Cheese Making, by Charles J. Hunt; and Cheese Making at Home: The Complete Illustrated Guide, by Don Radke (1974).

Demonstrations. Mary Jane Toth gives cheesemaking and cooking demonstrations. Call her to schedule a class (see books). Ricki Carroll (co-author of Cheesemaking Made Easy) offers all-day cheesemaking workshops on how to make gouda, fromage blanc, creme fraiche, queso blanco, mascarpone, ricotta, whey, mozzarella cheeses, etc. ($100; spring, summer). Get more info from the American Cheese Society.

CHEESE MAKING MAGAZINES, INFO, AND SUPPLIES

Ag-Innovations sells imported cheese vats, molds, and draining bags. Dr. Larry Faillace and Linda Faillace teach cheesemaking classes: 802-496-3998; aqinnov@madriver.com.

American Cheese Society schedules cheesemaking conferences, course panels and presentations, tours, a big annual convention with cheese-judging, and a list of American cheese producers: 502-583-3783; 304 W Liberty St., Ste. 201, Louisville, KY 40202. Their website posts conferences, articles, and their latest newsletter: www.cheesesociety.org.

The Basics of Making Cheese is a terrific British website that describes in downloadable detail the science and procedure of cheesemaking: www.efr.hw.ac.uk/SDA/cheese2.html.
(The) Cheese Reporter Magazine website has a searchable supplier directory, a wide choice of books and videos, and many links: www.cheesereporter.com.

The Cheesiest Site on the Net aspires to be the most comprehensive guide to cheese online, plus special reports on exceptional cheesemongers, dairies, and cheesemakers. It covers Cheeses, Essential Vocabulary, Links, Cheesemaking, and Cheese Retailers: www.erols.com/auraltech/index2.html.

Kusel Equipment sells 3A vats, finishing tables, air-veyors and curd elevators, presses and molds (such as 40-lb. “Wilson” hoops), submersible brine systems, and cottage cheese systems for large commercial producers: 920-261-4112; fax 920-261-3151; 820 W St., Watertown, WI 53094; www.kusellequipment.com.

CHEESE MARKETING: Selling cheese is about the easiest way to start selling dairy products off your homestead. You can use raw milk and age the cheeses 60 days, which will kill off the bad germs, or start with pasteurized milk (heat milk to 145–150°F for 30 minutes, then cool to 70°F and make the cheese). You can sell your cheese mail-order, from the farm, or through stores. American Country Cheese tells the start-up stories of 30 cheese companies.

Dairy Thermometer: All through this section you’ll be reading instructions to have your milk or curds at a precise temperature. For that, you need a “dairy thermometer.” This glass thermometer is made to float upright in liquid and be easily readable. It reads a range from about -10° to 220°F. Some are also marked in degrees centigrade. Available from any dairy or cheese-makers supplier.

Cheese Types: There are 5 basic types of cheese: soft, semi-soft, firm, hard, and processed.

Soft cheeses are unripened, fresh ones: cottage, cream, pot, ricotta, gjetost, Neufchatel. The soft cheeses that ripen naturally in just a few days include Brie, Camembert, and the double and triple creams, which have thin white crusts and almost fluid insides.

The semi-soft cheeses are ripened using specific types of helper bacteria and yeasts or molds: Basic Swiss, Brick, Muenster, Liederkranz, Limburger, Port Salut, Roquefort and Gorgonzola. These are among the most difficult for homestead cheese-makers because of the special organism culture you need and the special “ripening” conditions needed to control how they grow. Firm cheeses are Cheddars, Cheshire, Lancashire, Caciocavallo, Swiss Emmenthal, Gruyere, Jarlsberg, etc.

Hard cheeses are made like the firm cheeses but are matured to a grainy texture for grating: Asiago, Parmesan, Romano, Sapsago, etc.

Processed cheese is called “American” cheese and comes from factories, and thank God if you don’t have to eat it. It’s made of chemicals, artificial flavor and color, and a wide variety of other nondairy items with some milk thrown in. Your homemade cheese is just milk plus curdling agent.

Flavored Cheeses: Any cheese, hard or soft, can be varied by adding more or less salt, herbs, chili peppers, onions, chives, caraway, cumin, dried tomatoes, garlic, fennel, star anise, lavender, pink peppercorns, dill, rosemary, and savory. You can mix a crumbly cheese with nuts and dried fruit. Or wrap chunks of aged strong-tasting cheese in grape or chestnut leaves. Cheese can also be smoked.

Whey: Any time you make cheese, you get “whey,” which is the clearer fluid that you pour off from the curds. Don’t throw it away. Whey is terrific for animal feed, especially for pigs. In food value, 1½ gal. of whey equals 1 lb. of ground barley. NOTE: Don’t use galvanized containers for any cheese-making.

Making Soft Cheeses

Your homemade soft cheeses—cream and cottage, etc.—will seem different from the store product of the same name. If you read the ingredients on the store container, you’ll see why. For example, store cottage cheese may contain various additives, stabilizers, and preservatives, and is usually saltier than homemade. It also may have a creamy substance mixed in.

Cream Cheese: Cream cheese and yogurt are actually very similar. Yogurt is cultured whole or skim milk. Cream cheese can be made from more or less rich cream—even from skim milk!—which gives you, in turn, a higher or lower calorie cream cheese. “Cream cheese” made from milk instead of cream is called “Fromage Blanc” (instructions available from New England Cheesemaking Supply Co. Cream cheese will soon spoil, unlike your hard cheeses, and so after it’s made, it has to be protected from air, refrigerated, and eaten relatively soon.

You can substitute your homemade cream cheese in all those good recipes. A 3-oz. package equals 6 T of your own; the 8-oz. package means 1 c. of your own. Don’t store cream cheese in your freezer. You’ll cause weeping and destroy the texture, because when the ice crystals form they break up the fine consistency. This cream cheese takes 15–18 hours to set up. You can use yogurt culture or a regular cheese culture or a cultured buttermilk.

You can make cream cheese from regular cream, which contains 24–35 percent fat, but it improves it to add skim milk powder to increase the milk solids and reduce the fat. Pure cream cheese is very buttery. Store cream cheese doesn’t contain so much cream. Instead, dairies add a gelatin “stabilizer.”

Here are some of the old-fashioned ways to make something like cream cheese without using gelatin or powdered milk.

YOUGURT CREAM CHEESE: Pour freshly made yogurt into a cheesecloth-lined strainer or colander. Gather the 4 cloth corners and sides in your hands and tie firmly. Hang this yogurt-filled bag where it can drip in a cool, airy place for 6–48

10 HOME DAIRYING

771
You can work with any convenient amount since there are no other ingredients except salt “to taste” in the final stage. Don’t let the milk heat over HOT for traditional soft-curd cheese. Up to 120°F gives you the tough-curded “farmer” style cheese. One system is to take a half hour heating at the rate of about 2 degrees every 5 minutes to a temperature of about 90°F and hold it there for 3–5 hours, or until a wrinkled, leathery look appears on the surface, containing little pockets filled with a liquid resembling melted butter. Don’t stir or shake the contents. Don’t let it get too hot. When it is very wrinkled and drawn-looking, cool and again refrigerate overnight. The next day, skim off the thick top cream. This is your Devonshire cream. It is good with canned fruit or fresh strawberries. You’ll get about 1 pint of Devonshire cream.

COTTAGE CHEESE AND FARMER CHEESE: These can be made of skim milk, buttermilk, whole milk, or goat’s milk, but not very well of pasteurized milk because the natural souring process is key to good cottage cheese. If you must use pasteurized (store) milk, warm it to about 75°F. Then add 1 c. cultured buttermilk from the store. It will help also to use rennet (½ tablet to 1 gal. of milk), or, even better, a junket tablet, which has a milder action than rennet. Goat’s milk does not thicken as easily and has a softer curd than cow’s milk, so to make cottage cheese with it, it helps to mix in one-half or one-third cow’s milk. Otherwise it takes about 5 days to get goat milk sour enough for cottage cheese.

One qt. of milk will make about 1 c. of cottage cheese. You can work with any convenient amount since there are no other ingredients except salt “to taste” in the final stage. The best container in which to “set” the milk is a wide, covered enamel roaster, a canning kettle, heavy crockery, or a stainless steel bowl would all be fine. Do not use aluminum.

The larger volume of milk you work with, the easier it will be to control the temperature; 75–85°F is the temperature to strive for through the clabbering (thickening) process. Leave the milk on the warming shelf of your wood stove or some other warm but not hot place, similar to one you would use to raise yeast bread. (If you are using milk that is already sour, you would skip this step, of course.) Temperatures that are too low allow the proliferation of less-desirable bacteria. Temperatures that are too high will kill your bacteria and stop their creation of the lactic acid you need to clabber the milk. They will also toughen the curd.

The clabbering may take a few hours or a few days, depending on temperature and bacteria count. When the milk is “set,” it will have a jelly-like consistency. The solids will have formed one large curd, which floats on whey in the bottom. When the milk is sour and clabbered, you are ready to cut the curd.

Cut the curd using a clean butcher knife with a blade long enough to reach from the surface of the curd to the bottom of the pan. Make parallel cuts across the curd one way and then perpendicular parallel cuts across the other way to create squares between ⅛ inch and 1 inch on the side. If you are using a deep pan, rig up a galvanized wire to cut the curd horizontally at intervals between the top and the bottom of the pan. Now stir the curd very slowly and gently, endeavoring not to break up the curd but preventing it from clumping. The clumping tendency will be most pronounced at first and less so as the curd gets firmer with your final heating.

Now the curd is heated a little more to get it to just the right firmness. This is more art than science and depends on how you like your cottage cheese. The lower the temperature at which you stop, the softer your cheese curds will be. The higher the temperature, the firmer your curds will be. Don’t let the milk heat over 110°F for traditional soft-curd cheese. Up to 120°F gives you the tough-curd “farmer” style cheese. One system is to take a half hour heating at the rate of about 2 degrees every 5 minutes to a

### Of Gallons and Pounds

<table>
<thead>
<tr>
<th>Volume . . . Weight</th>
<th>Five gal. milk should yield you 4–4¾ lb. of finished cheese. That’s 10 lb. of cheese per 100 lb. of milk, or approximately 1 lb. of cheese per 10 lb. of milk.</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 pt. milk equals about 1 lb.</td>
<td>1 qt. equals 2 lb.</td>
</tr>
<tr>
<td>5 gal. equals 42 lb.</td>
<td>Exact weight varies according to your milk’s butterfat content. Dairy operations measure milk by the pound rather than the gallon.</td>
</tr>
</tbody>
</table>
To test the curd, pinch a little between thumb and finger. If a tiny bit remains on the ball of your thumb it is about ready. When you are satisfied that all the curd would pass the pinch test, you are ready to drain the whey. Dump the curd and whey into a cheesecloth-covered colander or a colander having very coarse holes and substantial interstices to hold back the curd as the whey drains away (save the whey for your animals). You can make something suitable by punching holes in a metal pan or can from the inside out.

If the milk is very sour you can rinse the curd with cold water and drain again. At this point you may want to hold back the curd as the whey drains away (save the whey for your animals). You can make something suitable by punching holes in a metal pan or can from the inside out.

Drain whey from curd; salt to taste

Heat very slowly to desired temperature, stirring gently

You now have dry cottage cheese. It will keep about a week or 10 days in the refrigerator (covered). The usual commercial product is "creamcd." You can add cream to yours at this time or before serving, but it makes more sense to do so shortly before serving because creamed cottage cheese does not keep nearly as well as the dry.

If you blend some "dry" cottage cheese with water and add tomato sauce and seasonings, you can make a salad dressing. With blue cheese in it, it's blue cheese dressing; with vanilla and sweetening added, it's a low-calorie imitation whipped cream.

Other ways to serve the cottage cheese are to press it into a dish and then cut off slices or roll it into balls. You could add ½ t. each: grated onion, minced green onion tops, or minced chives per cup of cottage cheese. Or you could mix in ¼ c. chopped stuffed olives, and 2 T. mayonnaise per cup. We like it with cream and honey and grated nutmeg on the top, but I've seen the horrified faces of enough cottage cheese-with-salt-and-pepper eaters to know it's all a matter of preference. You can also serve it mixed with celery seed or caraway seeds. Health-food fans might like their cottage cheese mixed with sea salt, garlic, and chives.

**EASY CURDS AND CREAM (ONE OF INFINITE VARIETIES)** Set your milk in a bowl until it becomes clabbered. Pour the clabbered milk slowly into a curd press (see "Making Semi-Soft, Firm, and Hard Cheese"). Let the press drain overnight. Turn the curds out into a flat dish. Grate nutmeg freely over the top, and serve with heavy sweet cream, more grated nutmeg, and sweetening.

**DORIS GRONEWOLD'S GOAT MILK COTTAGE CHEESE** You'll need 1 gal. of freshly drawn goat's milk—should be at 100°F. Dissolve ⅔ of a cheese rennet tablet in 2 T. warm water. Stir in the milk. This will set in 30 minutes. Stir the mixture to break the whey from the curds. Squeeze. Salt, chill, and serve. I sometimes add chives to mine.

**DRY CURD COTTAGE CHEESE** Sirniki and some other recipes below, call for "dry curd cottage cheese." That means natural cottage cheese with nothing added—no cream, no sour cream. To change store cottage cheese back to dry curd, rinse the "small-curd" type in cold water, then place in a sieve and squeeze the water out.

**SIRNIKI** From Ann Moran, Vancouver, WA: For this Russian entree, mix 3 c. dry-curd cottage cheese, 2 eggs, 2 T. sour cream, ½ c. flour, and 1 pinch salt. Shape that mixture with your fingers into golf-ball-sized masses. Sprinkle or roll some more flour onto the outside of the ball. Then press it down to a ⅛-inch thickness. Dust more flour onto it. Fry in a generous supply of melted butter, first on one side, then on the other. Set this on the table with a container of sour cream and another of fresh or cooked fruit chunks or sauce for people to combine as they please.

**COTTAGE CHEESE BLINTZES** Blintzes are a Jewish pancake. Beat 1 egg with a rotary beater until white and yolk are blended. Sift together 1 c. sifted all-purpose flour and ¾ t. salt. Alternately add flour and 1 c. water, a little at a time, to the egg. Beat until smooth and free from lumps. Break the surface air bubbles with a fork. Heat a 6-inch skillet over medium heat. Grease lightly. Using a ⅛-c. measure, pour 3 T. of the batter into the pan all at once. Tilt the pan quickly so that the entire bottom is covered with a thin layer of the batter. Cook on one side only. Invert on a clean tea towel. The pancake will slip out easily when it is done. Place a heaping tablespoon of the filling (recipe below) on the pancake. Fold the 4 sides over the center and invert on the cloth. Continue with the remaining batter and filling, and grease the pan from time to time as needed. This much preparation may be done in advance, and the blintzes wrapped in a tea towel and stored in the refrigerator; or they may be wrapped in foil and frozen.

At serving time, heat 4 T. oil in a large skillet or shallow baking pan. Place the blintzes in the pan, side by side without crowding. Brown over medium heat or bake at 350°F for 30 minutes (allow slightly longer if the blintzes were still frozen when placed in the pan). Turn over once during cooking, to brown both sides. This makes 11.

For the filling, mix 1 lb. dry cottage cheese, 1 slightly beaten egg, 1 T. sugar, ¼ T. ground cinnamon, and ¼ T. salt until blended. This makes 2 c., enough for the above recipe. If served as a dessert, ½ t. vanilla extract and ½ c. seedless raisins may be added. Serve with sour cream, or both sour cream and jam.
**SAVE-THE-SOUR-MILK VINEGAR-CLABBERED CHEESE**

This is a Sloppy Carlo's quick-and-easy money-saver that works for city people, too. You have a container of milk and your kid says, "Yuk, it's sour." Do you throw it out? Not unless you are a homesteader or a homemaker who's got a little extra time and a craving for a tangy, rich cheese. Start with about 4 qt of thick sour milk. When the milk is quite thick, pour boiling water over it, place in a cheesecloth bag, and let drain for 12 hours. Rub the cheese through a fine sieve. Work in 2 T. milk and 2 T. cream with a spoon until it is all the consistency of apple butter. Season with ½ t. salt and a very little pepper, if desired. Serve on buttered bread with apple butter.

**VINEGAR-CLABBERED SALTY CHEESE FROM FRESH MILK**

Here's how to do it right. You can do this with the above milk also. Heat milk to about 185°F. Add (about) ⅛ T. vinegar per 1 qt. milk. Stir vinegar in thoroughly. Let rest until it clabbers. Drain off whey through cheesecloth. Add ⅛ t. salt per 1 qt. of milk you started with. Mix well. Let drain several hours more. It's ready to use.

**COTTAGE CHEESE SANDWICH SPREADS**

Mix cottage cheese with finely chopped beet pickles; or nuts and cherries; or chopped green beans and green peppers; or finely cut nuts and pimento bits; or cucumber and celery bits, onion and paprika; or finely chopped Swiss chard and onion or pickle; or tomato chunks and chopped olives; or lemon juice and lettuce; or cucumber slices and tomato slices!

**COTTAGE CHEESE PANCAKES**

Sent by Bobbi McCullom from Canyon Country, CA. Combine 4 beaten eggs, 1 c. sour cream or yogurt, 1 c. cottage cheese, 1 c. flour, a dash of salt, and 1 T. sugar or honey. Fry on medium hot griddle. Serve on buttered bread with apple butter, cheese with finely chopped beet pickles; or nuts and cherries; or chopped green beans and green peppers; or finely cut nuts and pimento bits; or cucumber and celery bits, onion and paprika; or finely chopped Swiss chard and onion or pickle; or tomato chunks and chopped olives; or lemon juice and lettuce; or cucumber slices and tomato slices!

**NEUFCHATEL CHEESE**

Recipe from Mrs. Carl Sandburg and Doris Gronewold. You'll need 1 gal. freshly drawn goat's milk, ½ junket or rennet tablet thoroughly dissolved in ¼ c. cold water, and ½ c. smoothly coagulated sour milk (you can use sour cream or kefir or yogurt starters). Also: nuts, olives, onions, chives, etc. Cool milk to 75°F. Add ⅛ c. sour milk. Stir for 1 minute. Add rennet tablet and stir again for 1 minute. Do not disturb again, and keep in a warm room for 18 hours. Dip the curd into cheesecloth and hang to drip. Drain, but not until the curd looks dry; as the mixture doesn't seem to stick together when pressed. Put curd in bowl, salt to taste, add nuts or whatever you like. (Doris loves it with olives and nuts.) Press in a cheese press (if it's a homemade press, be sure the rough edges of holes in the bottom and sides are to the outside). Line with cheesecloth and ladle in cheese. Draw cheesecloth over the top. Place a wooden follower on the cheese, and apply a 50-lb. weight. The length of time required to press the cheese depends on the temperature and weight (12–24 hours).

**Making Semi-Soft, Firm, and Hard Cheeses**

The 2 parts of this book about which I feel the greatest sense of accomplishment are the descriptions of home-butchering and this cheese section of the dairy chapter. The home-butchering is described as a homesteader would do it, using simple language—something I simply wrote down as we did it. The cheese-making was a different sort of hunt. Professionals wouldn't tell me. They said things like, "You couldn't make cheese without a big factory and lots of expensive equipment and very controlled conditions."

I ordered a government book called Cheese Varieties that is full of what appear to be cheese recipes. But every time friends and I tried them—and in total that was a lot of
times and a lot of different recipes in the book—it turned out to be a moldy disaster. (A commercial publisher reprinted this book word for word, calling it Cheeses of the World, and it is still just as useless from the cooking point of view.)

Finally I got a recipe from Mary Simeone, who at the time was 9 months pregnant and living in a tent two-thirds up the side of an Idaho mountain, while her husband built a log cabin. She was milking 2 goats, and her finished cheese tasted very much like the good strong Greek and Italian cheeses that you can usually find only in city gourmet shops. Her recipe is the one I called “Basic Farm Cheese.” I like it because it spares you all the useless detail of the rennet company recipe. She aged her cheese by hanging it on the end of a string under the biggest bull pine she could find. That should encourage any of you who think you can’t make cheese without a factory. The fact is, from a historic view, factories are very recent arrivals on the cheese scene. Mary and her husband are from an Italian section of New York City, and they are making it fine now in Elk River, which is really out of the way, even for Idaho.

But my biggest breakthrough was in meeting John E. Montoure, Associate Professor of Bacteriology-Biochemistry at the University of Idaho, at a meeting of the Idaho Purebred Dairy Cattle Association, where my husband and I sort longed to the upper classes and were in the lap of luxury. He must have meant all those guys with 150 head of milk-curdling magic. It’s best in giant, thorny kinds. Regular purple thistle will work. Globe artichoke is a thistle. All species of Compositae thistles have the milk-curdling magic. It’s best in giant, thorny kinds. Regular purple thistle will work. Globe artichoke is a Compositae thistle variety, and can be used also. Cardoon is another option.

To harvest thistle for rennet, gather the thistle flowers when they have turned brown. If you see thistledown, the plant is over-mature. Get it right after the end of bloom and before the stage when down blows away. Air dry the flowers. You can store them in jars to wait until needed for cheese-making.

To use your veggie rennet, a quick way is just to tie a bundle of thistle flowers together with string and leave it in the milk until it clabbers. But the more professional way is to pound and extract. You take out enough—5 heaping t. of pounded dry herb will be needed per 1 gal. milk to be curdled. Pound in a mortar with your pestle until quite crushed. Then pour just a little warm water or whey over, just enough to cover. Let soak 5 minutes. Pound 5 minutes more. Repeat the soaking, and repeat pounding until you’ve pounded at least 4 times total. You should be seeing a dark (brown) fluid. Strain. Add the fluid to your milk. Be careful not to add too much of any veggie rennet herb because ex-

**Rennet**: Rennet is used to make these cheeses; you don’t rely on the natural souring that you use for cottage cheese because the use of rennet allows you to get out more water and that gives you a different kind and a nicer cheese. Even 3 percent less water makes a big difference in the final product. You can order rennet from the addresses I gave above. Your basic store rennet rule is to dissolve ¼ rennet tablet for each 2 gal. milk in ½ c. cool water. Add to milk that is 86–90°F Stir well. Cover and let it rest an hour, or until the curd is well-formed. If you have trouble clabbering your milk, use more dissolved rennet. Better too much than too little.

**Homemade Animal Rennet**. If you cared to, or had to, you could make your own rennet, since it is the salt extract of a suckling calf (that means one that has eaten no grass or solid food). You just take the biggest stomach of a suckling calf (or pig or lamb) that never has eaten anything but mother’s milk. The suckling calf has all 4 stomachs, but its rumen is underdeveloped and that fourth stomach, its abomasum, is relatively big; rennet comes from the abomasum. Add salt to it, cut it into strips, and dry it as if you were making jerky. To make cheese with it, cut off a 1-inch square and add it to milk. That would be the equivalent of 2 drops of liquid rennet.

**Vegetable Rennet**. Yes, you can make this from various plants. It never acts as fast as regular rennet. At best it will curdle milk overnight. You can make veggie rennet from yellow (lady’s) bedstraw, nettle, lemon or common sorrel, fumitory, unripe fig sap, or the giant purple thistle. Nettle and thistle are the best. All species of Compositae thistles have the milk-curdling magic. It’s best in giant, thorny kinds. Regular purple thistle will work. Globe artichoke is a Compositae thistle variety, and can be used also. Cardoon is another option.

To harvest thistle for rennet, gather the thistle flowers when they have turned brown. If you see thistledown, the plant is over-mature. Get it right after the end of bloom and before the stage where down blows away. Air dry the flowers. You can store them in jars to wait until needed for cheese-making.

**Culture:** You're familiar with that word from making yogurt, cultured buttermilk, and cultured cream cheese. Culture is a bacterial organism that you can order in a dried form from the addresses given above. Before 1940 they thought you couldn't make cheese with pasteurized milk. They soured milk the natural way, like for cottage cheese. The result was that some cheese-makers made good cheese, but some didn't. That's because their luck depended on what kind of bacteria happened to be plentiful in their cheesery. Some organisms will make a bitter cheese. Bad ones break down protein; good ones make an acid. The enzymes will break down some protein, but in a desirable way—so you get the flavor you want.

After 1940, cheese makers learned to pasteurize the milk to destroy the bad bacteria, then to add good bacteria—exactly the ones they wanted—to their "culture." When you use culture you have a choice to add or not to add rennet. That's because, given time, the good organisms will clabber the milk anyway. Factory cheese operations order frozen cultures, which are shipped by express in an ice chest with dry ice around them. You can also order freeze-dried cultures, and that's the kind you would prefer. Consult with your cheese-makers supplier about what cultures you need if you want to make any specialty cheese.

**Maintaining Your Cheese Culture.** After ordering the dry culture grains, you can keep your cheese culture going, same as you would yogurt. In fact, make yogurt with it and then you have both! Add some to 1 qt. of milk. Let set at 70°F Every 2 or 3 days, take out 1 1/2 c. and add it to another quart of milk to keep it going. Use a clean container and pasteurized milk.

But most homesteaders avoid all this struggle and use cultured buttermilk from the store dairy case to get their starter. They add 1/4 c. buttermilk starter to 1 qt. milk. Let work 24 hours at room temperature. Add your quart of home-cultured buttermilk to 3-5 gal. milk, warmed to 86-90°F and let ripen 1 or 2 hours. Now you're ready to add rennet. If you skip this step, your cheese may swell and not ripen properly. These are the "good" microorganisms that you want to ripen your cheese. If you don't fill your milk with them, you will have less desirable ones.

**Coloring:** Adding this is optional. But do not use butter; it colors only the fat.

**Moisture Content:** Most cheeses are made of the same thing—milk, usually skim milk. The different results are achieved by slight differences in dryness, acid content, or temperature. The temperature at which you cook it and the length of time you cook it controls the moisture content. More moisture gives you a softer body, a sharper taste, and a faster cure, but there is a tendency to develop off-flavors.

**Cheese-Making Procedures**

**Temperature.** This is really important! If you can't control the cooking temperature, you're going to end up with a different cheese each time. This doesn't mean it will be bad cheese though. In making these hard cheeses if you go much above 100-102°F, you will kill off the good organisms, which you don't want to do—ever. This is where hard cheese is different from cottage cheese. Hard cheese is made as much by the curing process as by what you do at the beginning, and it's the organisms working gradually in there that give you the cure.

**Pressing.** The traditional press for homemade cheese used to be a coffee can with nail holes punched through the bottom and sides. Now we know not to use coffee cans because some have lead solder. The acid in the whey may leach out the lead into the cheese. If you get your press from a cheese-maker's supplier, it will be lead-free. It's important to get the curds into the press (wrapped in a cloth) while they are hot. Then put your round wooden follower on top, and weights on that. The combination of heat and pressure drives off the
WHEY LEMONADE. Wherever you have cheese-making you have surplus whey. Lane Morgan tells me she makes a whey lemonade by adding juice of 2 lemons to 1 qt. of strained whey. Sweeten to taste with honey or sugar.

Salting the Curd. It's a good idea to add the salt in 3 portions. Add the first third, stir, add the second, stir again, and so on.

NOTE: Salt in your cheese adds flavor, but also helps release the whey and discourages growth of microscopic stuff that might spoil your cheese. If you want to make salt-free or low-salt cheese, you can do it, but your cheese won't keep as long.

Wrapping the Cheese. Professionals use a foil coated with wax into which the cheese ball is sealed. You could use foil inside of butcher paper. A cloth soaked in vinegar is easiest though. You have to freshen the vinegar at intervals. Paraffin dip is a good mold preventer. Just melt your paraffin, dip the cheese all around into it, and cool.

Storage of Curing Cheese. Curing temperature matters—45°F is best. At 45°F, a Cheddar cheese will have the right kind of flavor in 6–9 months. Curing at 48–52°F can give you an entirely different cheese. Turn your cheese over every day or so for the first month. Grease the bandage and rub it when you do that.

Storage temperature is the place where making cheese at home is rough compared to having the "factory conditions," which means having controlled temperatures and humidity. So just don't worry about getting your cheese precisely like the store version. It will still be good food and good cheese. Second, do your major cheese-making in the fall after the worst of the heat is over. Third, figure out the coolest place you have—the most nearly suitable. (Same problem as with storing apples.) For good-quality cheese, 60°F is too high. Your root cellar might be a good place, although you risk the cheese picking up an off-flavor from the vegetables there. The vital thing about a root cellar is that it remain dark as much as possible and maintain a constant and correct temperature and humidity. That means no windows and a door opened as little as possible. So if you wait until late enough in the summer so your root cellar won't be above 60°F, you could use it. Before then you could use your refrigerator. You must be very careful to keep all flies out of your curing place or you may get maggots in the cheese.

The size of your cheese also matters. Smaller cheeses have a greater tendency to dry out. Starting with at least 5 gal. of milk will help you here. But the milk shouldn't be more than 2 days old if you can help it. It's okay to skim it. NOTE: Resist the temptation to cut into and taste aging cheese until it's done. Under-aged cheese is drab in flavor compared to properly aged cheese, and your cheeseball needs an intact rind.

Storage of Finished Cheese. Cheeses with high fat content are the poorest storers. Shelf-cured cheeses will keep a while more on the shelf. Or you can keep any cheese for a while in the refrigerator, much longer in the freezer.

Drying Grating Cheeses. Low-fat "firm" or "hard" cheeses are best for drying. Grate or shred the cheese. In a dehydrator or oven, spread the cheese bits over your drying tray. It helps to lay the cheese on something absorbent like cloth or paper towel to absorb melted fat. Dry at 120°F, stirring once in a while for 6–8 hours or until hard. If you are sun-drying, dry in full sun in an airy place. This will take a day or longer. Use dried cheese like Parmesan to sprinkle over casseroles or spaghetti sauces. You can store as is dried, or pour into plastic bags and freeze.

Hard Cheese Recipes

BASIC FARM CHEESE: This process works fine with cow's or goat's milk.

1. Fill with whole milk a 9-quart enamel or stainless steel bucket (never aluminum!) to within about an inch of the top.
2. Warm it to 86°F. Use a dairy thermometer.
3. Add 1/4 rennet tablet (or a whole junket tablet), crushed, with 1 t. of water. Stir it in. (Your drugstore can order rennet for you.)
4. Let set quietly until it curds, about 20 minutes.
5. Cut into approximately 1/4-inch squares by cutting one way and then cutting the other (to make a pattern of squares on the top) and then by reaching in to cut across from top to bottom of the bucket.
6. "Bathe" the curds for 2 minutes with your hands. That means to move the curds around in the whey gently and slowly.
7. Set your enamel bucket in a dishpan of water back on the stove. Keep it covered with a cloth so specks and flies won't fall in or crawl in.
8. Slowly warm to 102°F (dairy thermometer again), stirring occasionally to keep contents at an even temperature. It will tend to get hotter at the bottom of the pan.
9. Take it off the stove and let it set an hour, stirring occasionally very gently.
10. Put cheesecloth over a colander. Fasten the edges with clothespins. Pour the cheese in there. Save the whey. You can feed it to the animals or make bread with it. All the vitamins are in the whey now.
11. Add 1 T. salt and mix with hands. Add another 1 T. salt and mix again.
12. Tie ends of cheesecloth together to make a bag. Hang it up where you can let it drip for the rest of the day.
13. Put a holding band around the edge of the cheese bag made of cheesecloth like a headband or belt. Put a
paper the fluted edge trimmed off over the cheese and one under it, and a heavy weight over it and a hard flat smooth thing underneath, and let it press like that all night. Something flat and iron is good to press it, or use a piece of wood with bricks on top.  

14. After it has been pressed all night, let it dry in an airy, cool place, turning it every few days until it forms a hard rind. If it molds, cut the mold away.  

15. Paraffin it. To do that you heat a block of store paraffin in a pan almost to boiling (210°F), then brush the hot wax over your cheese or dip parts of the cheese in until you have it all covered. Attach a string in there and you can hang it up in a cool place to age. At first your cheese will be tasteless and have the consistency of a rubber eraser. The flavor comes with aging. Give it 2 months at least. Be careful you have it thoroughly paraffined, or it may get wormy. 

**Colby Cheese:** Pasteurize 12 gal. of milk. Cool to 88–90°F. Add 2 c. of your culture (from “Maintaining Your Cheese Culture”). Let it set for 30 minutes. Now add 2 drops of liquid rennet that has been diluted in 1 c. of water. If you use tablets follow the manufacturer’s directions. They’ll say how much for 12 gal. Mix the rennet into the milk thoroughly for 3 minutes and then stop. It will take about 30 minutes to set up.  

Put your finger into the milk at a 45-degree angle. If the curd breaks cleanly, in a nice straight line, it is ready. Your finger won’t have goop on it, and the curd can be picked straight up. Now cut the curd. The more uniform the pieces you cut it into the better, because small ones will cook too fast and big ones will be undercooked, meaning they will still be fragile and will shatter. Cut as for cottage cheese.  

Let it rest 15 minutes. This is to “heal” the curd so it doesn’t break up when you start to stir it. Now heat it very slowly. The professionals go up 1 degree the first 5 minutes, 2 degrees with the second 5 minutes and so on (100–102°F is the very highest you should go). If you heat higher, your organisms will start to die, and the cheese won’t develop as you want. Use a cheese thermometer (same as a dairy thermometer). It will take about half an hour to get the temperature up if you are doing it just right. Set up some kind of a double boiler—like a 5-gal pail inside a canning kettle with enough water to come halfway up the sides. That will keep the temperature right.  

After you have gotten the temperature up to 100°F in this gradual way, drain off the whey, and stir the curd so it doesn’t form a single mass. Add salt to taste—maybe 3–4 T. for 10 lb. of curd. If you are on a low-salt diet you can substitute a potassium salt. If you didn’t salt at all you would get a bland cheese and a different type of fermentation because the salt holds back some organisms. Thoroughly mix. Put it in a sterilized cheesecloth and press. Start with 5 lb. of pressure for the first half hour to give it a chance to knit together. Gradually increase the pressure to 20–25 lb. It will be of a spongy texture now, not solid like a Cheddar. The cheesecloth closes up the surface of the cheese and gives you a nice product. (Resist the temptation to nibble.) The cloth also acts as a wick and draws moisture out of the inside giving it a path to travel out of the press. So, use a cloth whatever else your pressing arrangements. Press overnight—12–16 hours. Wrap the cheese as above.  

Now cure the Colby below 45°F. Curing above that temperature speeds up the process, but you risk a poor taste. If you cured it in your refrigerator it would take 9–12 months, assuming the temperature in there is 38–42°F. For the first month it would taste like “green curd.” At about 3 months you start to pick up a reasonable amount of Colby taste.  

**Monterey Cheese.** Same as Colby, only you “cook” at 100°F, holding it at that temperature for 1 hour and 45 minutes before proceeding.  

**Montoure Cheddar Cheese.** “Cheddaring” removes even more whey from curd after its first heating and draining. Monterey Jack and longhorn are cheddared cheeses also. Cheddaring helps cheese because it makes them have an even lower moisture content. Dryer cheese can age a longer time and keeps better.  

To make Montoure-system Cheddar cheese, proceed as directed for the Colby-type cheese until the end of the curd-heating process. The curd should be contracted to about one-half the starting size, firm, and without a tendency to stick when pressed together. Use an ordinary flat-iron to make a hot iron test. The curds, when rubbed on the clean hot iron and then drawn away, should show fine threads about ¼ inch long. When the curd passes this test, dip or pour off the whey, keeping the curd stirred with your hands as you do so.  

When the whey is off, put the curd in a deep, more or less rectangular pan that has a hole punched in the bottom to let whey escape. The top or bottom of an old fashioned roasting pan will work fine for a moderate amount of curd. Don’t let the curd cool off while you are draining and transferring it. Pile it evenly in the roasting pan and cut a channel through the cheese to help the whey drain toward a hole at one end of the pan. Keep the pan slightly tilted.  

Put the pan in your oven. You’ll want just enough heat in the oven to keep the cheese at a temperature of 98–100°F. Put a pan underneath to catch the whey. This is the Cheddaring process and will probably require some experimentation for you. Avoid too much heat. After about 20 minutes the curd will be firmly matted. Then cut the curd into blocks 6 inches long. Then turn them over so that what was the top of the curd is now underneath and next to the bottom of the pan. Continue the heating. All during your heating, try not to let the temperature of the curd get below 90°F. You’ll need a thermometer inserted in the curd to keep you informed. Turn the curd pieces about every 15 minutes. At the end of the third turning, pile the curd blocks 2 deep. In 15 minutes pile them again—but 3 deep if they seem dry enough. The Cheddaring process is done when the hot iron test shows you strings from ¼ to ½ inches long. (There is an easier acidity test, but you would have to use special equipment.)  

Next cut the curd with a butcher knife into small pieces about ½ inch wide and 1½ inches long. Then stir thoroughly for about 15 minutes before salting. Add 2 or 3 oz. of salt for every 5 gal. of milk that you started with. The best salt is cheese salt, obtainable from a dairy supply of

maybe from your drugstore. Its coarse, flaky consistency makes it more readily absorbed by the cheese. Spread out the curd, sprinkle the salt on, let it cool to 80-90°F; sprinkle on another bit of salt, stir thoroughly; and wait for the salt to dissolve. The curd isn't ready for the press until it is dissolved. Maintain your temperature throughout, and when you're ready to press, put the curd in the press at a temperature of about 85°F. Now turn back to the directions for Colby cheese and press and finish the cheese according to that. This Cheddaring process will take about 2½ hours in all. When you're done, the curd is all in little strings that look almost like a cooked chicken breast.

**W.S.U. EXTENSION CHEDDAR CHEESE:** Use fresh, clean, high-quality whole milk; 10-12½ qt. (20-25 lb.) whole milk will make 2-3 lb. cheese.

**Equipment.** You'll need:

A container that will hold 10-12 qt. of milk, such as a pail, kettle, or canner (rust-free)

A dairy thermometer

A long-handled spoon

A knife or spatula with a long blade (to reach the bottom of the container)

Measuring cup and measuring spoons

Dispan or container for draining curd

Cheesecloth for draining curd (large enough to fit over pan for draining)

A cheese hoop: a straight-sided, 1-gal. container (punch about a dozen holes in the bottom with a nail)

Cap cloths, the same diameter as the hoop, made of flour sack or muslin

A follower: a round piece of wood, 2-3 inches thick, slightly smaller in diameter than the hoop, so it will fit down into the hoop (be sure it is made of seasoned lumber that is not gummy!)

Weights: bricks or something similar that weigh 30-40 lb.

Bandage: cheesecloth or gauze for wrapping cheese

Paraffin to cover the cheese

**Ingredients.** You'll need 10-12 qt. pasteurized or raw milk; ½ c. cultured buttermilk for a starter; ½ t. liquid rennet (or tablets); ⅛-¼ t. cheese color; and 1½-2 T. salt.

**Pasteurize.** Heat milk to 145°F, and hold it there for 30 minutes. If the temperature drops, reheat slightly. Stir constantly to avoid scorching. Cool the milk rapidly to 86°F by setting the pan in a container of cold running water or in water chilled with ice. (If you use already pasteurized milk—just heat milk to 86°F)

**Add Starter.** Add about ½ c. cultured buttermilk for 10-12½ qt. milk. Get buttermilk as freshly cultured as possible. Allow milk to ripen at 86°F for 30-60 minutes. Maintain temperature at 86°F. Apply slight heat if necessary.

**Add Color.** Optional. Cheese made in the winter without color added will be white. Dilute ⅛-¼ t. liquid cheese color in ⅛ c. cool water. Stir thoroughly.

**Add Rennet.** Maintain milk at 86°F and add rennet: about ⅛-½ t. liquid rennet diluted in ⅛ c. cool water. If using rennet tablets, follow directions. Stir in rennet to mix thoroughly. Cover and maintain at 86°F. Let milk remain undisturbed for about 30 minutes to coagulate. (If disturbed, curd may break and become grainy, and the whey will separate before the curd is ready to be cut.)

**Cut Curd.** Test the curd to see if it is ready to cut. Insert your forefinger at an angle in the surface of the coagulated milk. If the curd splits cleanly, and clear whey fills the opening, the curd is ready to cut. With a clean, long-bladed knife or spatula, cut the curd into ⅛-inch pieces. Cut straight down across curd from one side of the container to the other, being sure to cut to the bottom of the container. Cut several times in each direction, making right-angle cuts. Then turn the knife blade at about a 45° angle and slash at that angle several times in each direction to cut the strips into shorter pieces. After cutting, stir occasionally, being careful not to break the pieces of curd.

About 15 minutes after you finish cutting the curd, heat slowly to 100-102°F (takes about 30-40 minutes). Hold at this temperature until the curd reaches the desired firmness.

**Test for Firmness.** Squeeze a handful of curd, and release suddenly. If it breaks apart easily and shows little tendency to stick together, it is at the desired firmness. If it is soft and pasty, hold longer. If too firm, the cheese will be dry and cory.

**Remove Whey.** Allow the curd to settle to the bottom of the container and dip off most of the whey. Pour the curd and remaining whey over cheesecloth that has been stretched over a large container. Allow the whey to drain off. Stir occasionally to keep lumps from forming.

**Salt.** When the curd has cooled to 90°F and is slightly rubbery in texture (squeaks slightly when you chew it), sprinkle on 1¼-2 T. salt.

**Hoop.** Place 1 cap cloth in the bottom of the hoop. As soon as the salt has dissolved and the curd reaches about 85°F place the curd in the hoop. Be sure the curd is not below 85°F. If cooling rapidly, begin with curd at 88°F. Place the other cap cloth on top of the curd.

**Press.** Place the wooden follower on top of the cap cloth and add 12-15 lb. of weight for 5-10 minutes. Increase the weight to 25-30 lb. and press for 30-60 minutes.

**Dress.** Remove the weights and follower, and turn the hoop upside down so the cheese will drop out on the table. Remove the cap cloths and dip the cheese in warm water (about 100°F) to remove any fat from the surface. Cut a bandage 2 inches wider than the cheese and long enough to wrap around the cheese with a 1-inch overlap. Wrap the cheese tightly in the bandage. Replace the cap cloths and put the cheese back in the hoop. Replace the follower and press the cheese with 30-40 lb. weight for 16-20 hours.

**Dry.** Remove the cheese from the hoop and wipe away any surface moisture. Be sure there are no cracks in the surface. If there are, remove the bandage and dip the cheese in warm water again to soften the surface, rebandage, and put back under weights for about 1 hour. When the surface is smooth, put the bandaged cheese on a shelf in a dry, cool room. The temperature during drying should be 50-60°F. Turn the cheese and wipe it daily. As soon as the surface feels dry and the rind begins to form—in 3-6 days—paraffin the cheese. (If a rind has not started to form by 6 days, the cheese should be put in a drier place.)

**Paraffin.** Heat paraffin to 210-212°F in a pan deep enough to immerse half the cheese at a time. Be sure the surface of the cheese is dry. Do not remove the bandage. Hold the cheese in the hot paraffin for about 10 seconds. Let dry, then immerse the other half.

**Cure.** After paraffining, the cheese is placed again in the dry room at 50-60°F. Turn the cheese often to keep it clean.

**Curing.** Keep in a dry room at 50-60°F. Turn the cheese often to keep it clean.
and free from mold. Wash the shelf under the cheese, and dry it to keep mold from forming. Cheese cured for 6 weeks will have a mild flavor. If you want a sharp flavor, cure for 3–5 months longer. The cheese will cure more slowly if the temperature is below 50°F.

**GRATING CHEESE:** This is a firmer cheese that you grate and use the way you do Parmesan. Make it from skim milk. Clabber, cut, and cook in the whey same as Colby. Only don’t cook just a half hour; cook for 2 or 3 hours. After it is nicely cured, go ahead and grate it. You can add additional seasoning to suit yourself.

**PROFESSOR MONTOURE’S DEEP FAT FRIED CHEESE:** Fry chunks of pressed curd. The pieces are cut ½–1 inch long, similar to French fries. They keep their shape and have a nice flavor. Do this with “green curd”—fleshly made cheese. You can’t do it with aged cheese.

**ROQUEFORT CHEESE:** You can’t make genuine Roquefort unless you have sheep’s milk. You can blend sheep’s and cow’s milk and still get the right flavor. Even 1 part sheep’s milk to 9 parts cow’s is okay.

**BLUE (OR BLEU) CHEESE:** Blue cheese is very similar to Roquefort, except you can use cow’s or goat’s milk to make it. Blue mold is the most common one. You may have some around the house right now. It’s a penicillin-type mold. It is also used to develop Tilsit, Roquefort, and Gorgonzola cheeses. This is another case in which you can’t be afraid of mold. Unless it’s unbelievably foul, you don’t discourage the mold. One problem with making this, though, is the mold tends to spread and you may find it on other things besides your blue cheese, especially if you have a humid environment. A cloth soaked in vinegar discourages it. Use a fairly heavy cloth, like good cotton flannel. But the vinegar will evaporate, so you must keep it refreshed. This is to protect your other cheeses. Paraffin would protect them completely; mold must have air to grow. If another kind of cheese does get moldy, scrub the mold off with vinegar. Wait until it dries. Then dip into paraffin and it should keep. Some mold on the outside doesn’t hurt the inside a bit, even if it is in a thick layer.

Start to make your blue cheese with 5 gal. milk. That will give you 3½–4 lb. of cheese. Use raw milk—don’t pasteurize it. Shake part of the milk to get air bubbles in it. You can put a quart in a blender for 5 seconds and then add it to the other milk. Or shake some in a half-gallon fruit jar or use an electric mixer. Just a portion of it thus shaken will do. Now add your culture. The same as with Colby. Use 1 c. of culture. Now have your milk lukewarm and add rennet —1 drop of the liquid or an appropriate amount of the tablet kind, or ½ square inch of the calf’s stomach. When it has set up, cut the curd. Mix well but don’t agitate more than 3 minutes. Cut 1-inch-square chunks. These are larger than for Colby. You want a softer curd in this case. Let set 15 minutes. Now turn the curd slowly. You don’t want to break up the curds. You don’t want dry blue cheese.

Now bring the temperature up gradually and cook for 2 hours at 100°F in your double boiler. Drain. Add your blue mold. You could buy a pound of the freeze-dried mold from a dairy supplier. It will keep practically forever. All you need to make your batch of blue cheese is just a pinch stirred in.

Now mix in ½ t. salt and get ready to drain the cheese. In this case you don’t wrap in cloth. And you don’t put pressure. Make a cheese hoop by taking a straight-sided can that is about 6 inches in diameter and 6 inches or so deep, like a 6-inch stovepipe, and poke nail holes in the sides from the inside out so you won’t have rough edges inside. Make the holes about every 1 or 2 inches on the sides. Make a follower for each end. Any piece of board that was the right size and shape to barely fit into the can or pipe would be fine. Now put the first follower on the table. The pipe goes on top of that. The cheese goes into the pipe. And put the last follower on top of the cheese and turn the whole thing upside down. Keep doing this every half hour for 2 hours. The cheese will be cooling off. Water will be running out. The central mass will be holding its shape well enough.

Take the cheese off the follower and set it instead on heavy burlap, a towel, or 3 or 4 thicknesses of sheeting. But not on paper—that would cause the cheese to get soggy on the bottom. And let it set like that for 12–16 hours. Now rub ½ T. salt on the surface (iodized table salt is fine). It won’t all go on at first. Do it once a day for 5–7 days. You’re salting the curd from the outside. The moisture will come out, grab the salt, and go back in. After the week of salting comes the poking.

Take a ¼-inch knitting needle and poke holes in the side of the cheese, 1 inch apart all over the surface and deep enough so you come clear out the other side. Then tip over the cheese and do the same from the other side. This is to allow air inside so mold can grow inside (because mold must have air). Then let the cheese set at 45°F in a humid place. You don’t wrap it, of course. If you set it in the refrigerator everything else would probably mold. Incidentally, this blue mold won’t make you healthy eating it—it’s different from the one the doctor prescribes. It takes 4–6 weeks to be properly cured. You want mold on the surface as well as in the center. The mold colors will vary from blue to gray. If you get black, wash that off with vinegar and then let it go again. Or use a mild salt solution and a soft brush. At a higher temperature it would be ready even sooner. After it has arrived at the flavor and ripeness you like, you can wax it or put it in a cold place to store. But if you freeze it, it will turn crumbly.

**Growing Bleu Mold Starter.** Or you could grow your own by getting some blue cheese or Roquefort from the grocery store. Then you set some of the cheese on a damp slice of bread. Any kind of bread will do. And put it in a jar with holes punched in the top lid or with a cloth over the top. In 1 or 2 days, or maybe even as long as a week, your bread with the cheese on top will also be good and moldy. Then remove one-fourth of your slice of bread, dry it, crumble it, and you have enough blue cheese mold to make a batch of this cheese. Save the other three-quarters and each of them could make a batch, too. Remember, when you dry the bread, don’t do it in an oven. Just leave it out at room temperature because you don’t want the mold spores to die. You can keep your culture going by taking one-quarter of the molded bread and putting it on a fresh damp slice of bread again. In the good old days, even commercial dairies used this method for growing mold spores.

**ITALIAN CHEESE:** This is a cheese made especially for grating. Heat 10 qt. fresh milk to 85°F. Add ½ rennet tablet dissolved in cold water. Wait 40 minutes to let the curd get firm, then break up the curd with your hands, and heat it in the whey until it is as hot as your hand can stand. Gather the curd with your hands, and mat it together until it is

780
firm. Remove the curd from the whey and put it in the cheese press. Press one side, then reverse it in the press and squeeze some more. Put the curd in its sack back into the whey and heat (don’t let it boil). Remove from the heat and let the cheese stay in the whey until all is cold. Remove and let drain for 24 hours. You could now eat the cheese, but for the proper grating cheese rub it with salt and let dry in your curing room for 3 days or so. When it is dry, put it in a jar of salt brine for another 3 days. Make the brine so strong that there is salt undissolved in the bottom. Then put it drain for 24 hours. You could now eat the cheese, but then just leave it in the crock for 3–6 months. Now your cheese is completely cured and ready for grating.

**Twenty-Minute Cheese:** (This and the next recipe are from “Home Cheesemaking with Goat Milk,” a pamphlet available from Dairy Goat Journal.) To 3 qt. fresh goat’s milk at blood heat (98.6°F), add 1/4 t. liquid rennet. Stir gently. As it thickens, which is almost immediately, add 1 qt. boiling water and continue to stir gently, separating the curd from the whey and firming the curd so it can be handled at once. Place a reed cheese basket in a colander and dip the curd into it, pressing down. When all the curd is in the basket turn the basket over, dump the curd out, and put it back in with the bottom side up. Thus the reeds will mark the cheese on all sides. If an unsalted, uncured cheese is wanted, it may be eaten now.

To cure the cheese, leave it in the basket for 36 hours, or until it is firm enough to keep its shape. During this time keep it in the kitchen or any other warm, dry place, and slip it out of the basket twice a day and turn it over. When firm enough, remove from the basket and keep on a plate in the kitchen or pantry. Sprinkle dry salt on the side that is moist. Squeeze some more. Put the curd in a sack back into the whey and put it in the press, changing the cheese every few minutes. Press, turning daily for 10 or 12 days, changing the cheese for as long as 6 months.

**Cheese à L’Obispo:** Get a bottle of rennet tablets for cheese (not junket). Use about 8 lb. milk; put in rather more rennet than suggested in the instructions that come with the rennet. Let it set an hour. Cut curd, and heat to 98°F, no higher. Stir gently every few minutes. Cover and set away for an hour longer. Drain on a sieve lined with muslin and pack into a mold, salting away for 24 hours. A circular piece of stout tin should fit inside the can for a hollow center. Now for weight, use a quart jar filled with sand. Line the mold with thin muslin. Take out of the mold and set it on a screen tray in an airy place, with a soft folded cloth under the cheese, and a bit of muslin over it to keep off the dust. Press, turning daily for 10 or 12 days, changing the cloth underneath each time. It is now sufficiently cured to eat. Melt paraffin in a tin lid and turn the cheese carefully in it until it is well coated.

Your cheese can be eaten now, or cured for as long as 6 months. In damp weather the cheese will mold on the outside before fully cured. If it molds, clean off with a cloth dampened in vinegar and wipe dry.

**About Swiss Cheese:** This is a very delicate cheese for which everything has to be just right. To get good eye formation (the holes) you need a very large cheese. They cut it up in little pieces to sell it, but if you make a ball of less than 40 lb. (that would require 60 gal. of milk), the eyes won’t form right. You also need very little temperature change—the other thing that is difficult to manage at home. Sometimes, even in the factory Swiss cheese goes a little wrong and the gas inside explodes—cheese blows all over the room! Other times it makes no eyes at all.

Swiss cheese makers use a special culture, not the general Cheddar culture but a half and half mixture of Streptococcus thermophilus and Lactobacillus bulgaricus. They may also add another bacteria, an “eye former” (Propionio bacterium shermanii) during the cooking operation. The “eye former” has to be kept refrigerated. The genuine outer rind is really tough on a Swiss cheese in the making.

**Cream**

This is where goat’s milk and cow’s milk are so different. Technically, cream is just the globules of fat that have been held in suspension throughout the liquid.

**Cow’s Cream:** In cow’s milk the globules soon rise to the top due to their comparative lightness (oil floats on water). The longer the milk sets quietly, the more cream there will be—for the first 48 hours. But it isn’t worth waiting all that long. You get most after 12 hours, and most of the rest after waiting 24. The heaviest cream, which is called “whipping” or “sponge” cream, is closest to the top in a thick layer. I prefer cow’s milk because I enjoy homemade butter and whipped cream. I like having a little pitcher of cream to pour over strawberries, or a big one to make ice cream.

**Goat’s Cream:** You find goat’s cream on the top in the same way, only it takes longer to rise and there is never as much. There is butterfat in goat’s milk—in fact, it averages 3.5–4 percent! But goat cream doesn’t come nicely to the top for skimming like cow’s cream does. You can get some goat cream if you let it set long enough, but by then it’s almost sour. So to get goat’s cream you have to use a mechanical separator. Or you can get goat’s butter by churning the whole milk.

**Separating the Cream**

**Skimming:** I keep my milk in gallon jars or 5-gal. buckets (when I have that much) in the refrigerator. I skim the cream off at the end of 24 hours unless I need it sooner. The best thing is a regular skimmer. Mine are antiques. I don’t know if you can still buy them or not. A skimmer is a long-handled utensil with a cup fastened on the end. You set the cup into the cream so that the rim is just barely below the liquid’s surface. That way the part of the liquid that flows over into the cup of the skimmer is the top cream and not the milk underneath.

When you get used to it, you can do a very precise job of separating the cream from the milk and getting the cream out. Your jar, of course, has to have a wide enough mouth so the skimmer can easily fit in and out. Old-fashioned recipe books often say to let the cream rise in a shallow, wide container. I can’t understand why. I find the cream is much easier to skim off from a tall, deep container. When you skim cream, you never get it all because the lighter
portion stays mixed in with the milk—though if it sets longer, a greater percentage rises and can be skimmed. So a 48-hour sit yields more cream than a 24-hour sit. But the first cream is denser and better for whipping and butter-making.

**Separators:** These separate cow’s milk from its cream content very thoroughly. The separator is set to deliver cream at a certain percentage of butterfat—for example, 30 percent. Some people like them. Mostly they’re the people who milk a lot of animals and sell their milk and cream. Or else it’s people who have numerous goats, because their separator makes it possible for them to enjoy goat cream and butter. You have to take them apart, wash all the parts, and dry them after each use. It’s a lot of work. My separator has 18 disks, 17 other parts, the wrench—plus jars and milk pails to wash morning and night. Because of all that cleaning, it’s much easier for me to get cow’s cream by just letting the milk set in a gallon jar for 24 hours and then skimming. I used to separate but don’t bother now.

**Buying a Separator:** For years it was impossible to find a hand-cranked cream separator except at an auction. Now you can order one from any dairy supply company. Lehman Hardware offers a hand-cranked model whose bowl holds 11½ qt., very like the one my parents used. You can also get them from New England Cheesemaking Supply Co. (413-628-3808; www.cheesemaking.com). Separators can be adjusted to manage the percentage of butterfat you remove from the whole milk.

**Using a Separator:** Separators work on a centrifugal principle. The milk is supposed to be put through while still warm, at least 90°F. For separating in winter, you could flush some warm water through the separator first. But I know people who put it through cold and it seems to work all right. A table-type separator has to be bolted to a very sturdy tabletop. The hand-cranked ones won’t separate properly unless you have the crank moving at the proper speed. It is supposed to click. You keep going faster until it just quits clicking and stays at that speed. If you crank too fast you’re going to throw away a rather high percentage of your cream. Don’t go by the clicks of somebody else’s separator unless it is the same model and the same make. Different ones require different speeds.

**Separating Goat’s Milk.** Goat’s milk is hard to separate even with a cream separator. Make sure you have a model that can be set specially for goat’s milk. Otherwise it won’t work. You can save your milk for several milkings, and then separate it all at once. It even works with cold milk if you have the right setting on the cream percentage. The special thing about goat’s milk is that the fat globules are so much smaller.

**Buying a Separator.** For years it was impossible to find a hand-cranked cream separator except at an auction. Now you can order one from any dairy supply company. make butter from. Sometimes the farther a cow gets into her time of milking, the harder it is to get the butter.

NOTE: The latest medical research has established that people who eat real butter over a lifetime live longer than margarine-eaters! I have that directly from 2 friends who are medical doctors and who are now urging everyone they know to switch back to butter.

Whipping Cream

Secrets of Whipping Cream

1. Success partly depends on your dairy animal. Milks—and creams—are different. Store-bought "whipping cream" is different yet, containing the likes of "mono and diglycerides, guar gum and carrageenan." But you can whip your home cream without those added ingredients.

2. If your top cream seems too thick to whip you can add some milk before whipping—but not too much, because cream has to have at least 30-percent fat, or more, to whip properly.

3. Fresh cream doesn't whip well. Age it from 12 to 24 hours before whipping.

4. Forty percent butterfat or higher, pasteurized, freezes best, and will still whip up after freezing.

5. Whip chilled cream because warmth thins it.

6. Use a big deep bowl to whip in so it won't splash all over.

7. Stop whipping when the cream gets firm enough to hold a peak when the eggbeater is pulled out. If you keep going, it makes butter—which happens quickly and can't be reversed.

8. One-half cup whipping cream gives you about 1 c. whipped cream.

9. With a very sweet dessert you can use unsweetened whipped cream, and it will taste fine.

10. Don't add your sweetening if it is a liquid, like honey or molasses, until you have your cream all whipped. Then stir it in gently. A couple drops of vanilla improves whipped cream's flavor.

11. You can make ahead a stabilized whipped cream by sprinkling ½ t. unflavored gelatin over 1 T. cold water in a small bowl. Set that bowl into hot water until gelatin dissolves. Let cool. Whip 1 c. cream to almost stiff. Add dissolved gelatin, and finish whipping to stiffness. Cover. Keep in refrigerator. Mix with a spoon right before you serve it. Optional: pinch salt, ½ t. vanilla, 1 T. sugar.

Quick Creamy Chocolate Frosting

Whip 1 c. cream. Gently stir in ¼ c. instant cocoa or chocolate milk drink powder.

Lemon Creamy Frosting

Combine 1 ½ c. heavy cream, ¼ c. sugar, 1 ½ t. grated lemon peel, and several drops yellow food coloring. Beat to stiffness.

Butter

To churn butter, you shake, beat, or agitate the cream until the butterfat has separated out and formed a big glob.

Goat's butter is white rather than yellow and has a different taste than cow's butter—doesn't taste as buttery to me. There's a difference among cows' milks, too, but not nearly so much as between cow's and goat's. Butter-making is also affected by your cream's whipping ability. You may find that your particular cow's cream is harder than the average to

Butter Churn Types

Plain Jar. If you don't have a butter churn, the simplest way to make butter is probably to put your cream in a quart or half-gallon jar and give it to the children to roll back and forth across the floor. It takes 15-30 minutes for the butter to churn.

Rotating Barrel. You can buy one of these from Lehman's Hardware (888-438-5346; www.Lehmans.com). It is sold as a "pressure washer" for washing clothes (and it is useful for that), but if you have more than a little cream, it also makes a great butter churn.

Drill Churn. There is an electric drill attachment for stirring paint that could also churn butter if you simply put an electric drill through a hole in the metal top of a wide-mouthed gallon (or larger) jar and rigged up paddles to fit, and then fastened on the drill.

Electric Mixer. Butter can be churned using an electric mixer, but you have to watch carefully and remove the mixer just before the butter starts to come. Finish by beating it with a spoon or churning it in a jar as first mentioned. Otherwise the mixer would shred the butter and it would be very hard to gather together again.

Blender. Food writer Lane Morgan says, "I think a blender is the way to go for small batches of butter. It's easy and fast—4 or 5 minutes instead of 20 or so. Also, you can see what's happening. You just pour in the cream and turn it on a low setting. Scrape down any of it that whips and pretty soon it will separate into butter and buttermilk. I've made many a pound that way. (And I'm with you; I like sour milk best for butter.)"

Crank-and-Jar Churn. Our Sears and Roebuck's Farm Catalog carries 2 sizes of electric churn: a 1-gal. jar (it will churn 3 qt.), or a motor and dasher, which can be fitted on a 2-, 3-, or 5-gal. jar, or used on a crock. You can get an electric or nonelectric jar churn from Lehman Hardware.

Dasher Churn. A familiar sight in antique stores is the tall, upright crock churn with a lid through which is run a
wooden dasher. You stand or sit by the churn and work the
dasher up and down until the butter comes.

**Cream Content:** Anything from whole milk to "spoon
cream" (so thick it won't pour), either sweet or sour, can be
 churned for butter. However, churning whole milk is hardly
worth your while, since a quart of milk makes only about a
teaspoon of butter.

**Cream Temperature:** About 60°F is ideal. If the cream
is too warm, the butter is long in coming and is too soft
to handle. If it is too cold, it also takes too long to come, and
only part of the butterfat separates from the cream, leaving
a very thick buttermilk. The cream may churn easier if you
wait until it is not too sweet. The taste of your butter is af-
 affected also by how sour the cream is that you use. I prefer
butter made from sour cream, but not so sour that it has 3
 colors of mold on it. I've heard that the feed your cow has
been on can also affect the churning, that cottonseed meal
and timothy hay for some reason are trouble. Sweet cream
takes longer to churn and doesn't give as much butter
 proportionately.

**The Churning:** Don't ever fill up a container in which
you want to churn, because as it whips it doubles in bulk
and will slop out the top. Leave it at least half empty. It churns
 easiest when the container is only one-third full. So for the av-
 erage paddle churn of 3-gal. size, use about 1 gal. cream.

The churning should be done at a set rate and not too
fast. It takes about 20 minutes of steady churning until you
first hear the splash of butter and feel the stiffness in churning.
It is best to churn past the first coming of butter to be
sure you get all the butterfat from the cream. If you are us-
ing a big barrel churn with a bunghole to let out the buttermilk,
stop turning when the granules are the size of wheat
grains. You can tell with experience because the sound of
the cream in the churn changes. Let the buttermilk out
through the hole and run it through a strainer to catch any
 particles of butter.

**Washing and Gathering:** The next step after
churning is to wash and gather the butter. Some wash first
and gather after. Some do both at once. If you are working
with a large churn that has a bunghole, you could add pure
clean water and twice as much buttermilk as you drew off
after replacing the cork. Rotate the churn about 4 times,
then drain that wash water, and repeat with clean water.
Then commence to work the butter. About ¼ oz. of salt is
 added per pound of butter, or according to your taste.

To work the butter by hand pull the bung on a paddle
churn and drain off the buttermilk. With a spoon remove
the butter to a bowl, and scrape the butter from the paddle.
Remove pieces of butter in the buttermilk. You will get
2½—3 qt. buttermilk and about 1 lb. of butter from 1 gal.
cream. If the temperature is 80°F or so, you can't work but-
ter until you've chilled it. Pour cold water on it to chill it.
Now gather it into a ball, press it into a thin layer, and then
gather into a ball again, ad infinitum, until all the salt is well
worked in and the buttermilk is worked out. There is an
old-time machine called a "worker" that you rinsed with
hot water and then with cold, and then used to press the
butter into a thin layer, fold it into a pile, and press again.
It was great for large quantities of butter and for mixing the
salt into the butter.

To wash and work the butter at the same time, put the
butter from the buttermilk into a large bowl of ice water,
and squeeze it gently between your fingers until it feels
smooth and waxy. It should go through several bowls of
cool water. When the water stays clear, repeat 1 more time.
Then shape into a cake and pat to remove the extra water.
Next salt to taste and work the salt in well. The habit of
salting butter originated from the preserving power of salt.
Unsalted butter does not keep as well. In some countries
like Australia all butter is unsalted. Butter can absorb odors
if it isn't kept covered. But ours usually doesn't last that long.

**Coloring:** The color of cow's butter may vary. There is a
coloring product on the market for butter and cheese. It is-
the kind that is dangerous to health. But color never did
matter that much to me.

**Storing Butter:** Make sure all the buttermilk is out.
You can brine the butter first by making butter balls the size
of a baseball. Cover them with brine strong enough to float
an egg. Cover and store in a cool place. This is good for
months or even longer under cool temperatures. If you
have the salt you can cover them with layers of pure salt.

**Ghee:** Hot Climate Butter Storage. Certain volatile
fats in butter can get rancid. If it is heated enough that
they're driven off, then it doesn't taste like butter any more,
but it keeps much better. This is what folks on the Indian
subcontinent and in Africa do. You heat the butter at sim-
mmering about an hour. Don't let it brown. Skim off the
scum that rises to the surface again and again. At the end
you'll see a clear yellowish fluid in your pan. Pour through
a few layers of damp cheesecloth to remove the sediment
that went to the bottom. More straining gives you greater
keeping power. Pour into a scalded container. Cover to
keep air out. It will store nicely now for months, even at
hot temperatures.

**Ethiopian Spiced Ghee.** Gradually melt 1 lb. butter
(unsalted) in a pan and then bring to a simmer as above.
When foaming begins, add 4 T. chopped onion, ⅓ T.
chopped garlic, 2 T. grated fresh ginger, ⅓ t. turmeric, 2
crushed whole cardamom seeds (or ½ t. ground cardamom),
1-inch stick cinnamon, 2 or 3 whole cloves, and ½ t. ground
nutmeg. Simmer, uncovered, until solids have gathered on
bottom and the middle liquid is clear. Strain 3 times through
damp cheesecloth for longest keeping.

**Shaped Butters**

**Butter Molds.** Before using a butter mold, scald it, then
soak it in cold water for an hour. Pack it solidly with butter
and level off the top surface. When the butter is molded it
can be pressed out.

**Butter Balls.** Scald a pair of wooden butter paddles, then
soak them in cold water for about an hour. Measure the
butter by teaspoonfuls so the butter balls will be about the
same size. Have the butter firm but not hard, and roll each
spoonful lightly between the paddles to form the balls.
Drop onto a chilled plate, onto cracked ice, or into ice wa-
ter. Or press each ball slightly to make it round on the side
and flat on the top and bottom.

**Butter Pats.** Shape your butter into a rectangle the shape
of the commercial quarter pound. Let it cool to firm. Cut
neat squares off the end to be your pats. To decorate you
could dip a fork in hot water and draw on them or put a lit-
tle sprig of parsley on each one.

**Butter Curls.** These were traditionally made with a "butter
curler." It was dipped into hot water and then drawn lightly
and quickly toward you across the butter. This made a thin shaving of butter that curled up. The butter curler was dipped into hot water after each curl.

**Whipped Butter.** For a soft, fluffy spread, bring ¼ lb. butter and ⅛ lb. water to room temperature. Whip them together with the mixer. You might need more water. That’s all there is to it.

**FLAVORED BUTTERS**

**LEMON BUTTER** Cream butter until fluffy and add a few drops lemon juice. Use for sandwiches, canapes, and fish.

**HERBED BUTTER** For each ½ c. butter add about 1 t. of your choice of dried herbs (basil, thyme, marjoram, dill are fine) or chopped fresh herbs. A dash of garlic salt is good, too.

**BUTTERMILK**

**CHURNED BUTTERMILK:** This is the milk substance left after you have churned your butter. It may have an acidic flavor and it may not. It depends on how sour the cream was when you churned. Sour cream makes a sour-flavored buttermilk. If you want nice buttermilk, don’t let your cream go too rank before you churn. The “dried buttermilk” that you used to be able to buy in the grocery store was the real thing—dried.

**BUTTERMILK RECIPES:** There are so many great things you can do with buttermilk. In any of the following recipes you can use store-bought buttermilk or the yogurt–butter mix I mentioned, or your homemade buttermilk left over from churning if it’s nice-tasting. In baking you can use even a pretty strong-tasting buttermilk, and it will still turn out deliciously. It makes a fine gravy.

**BUTTERMILK CHEESE** Go through the usual steps. It will make the best cottage cheese or hard cheese of all!

**STRAWBERRY-BANANA BUTTERMILK** Mash and beat together 1–2 c. strawberries, 1 banana, and 2 c. buttermilk. A very special beverage.

**ORANGE-HONEY BUTTERMILK** Combine 4 c. buttermilk, the juice of 2 oranges, and 2 T. honey.

**BUTTERMILK COLESLAW DRESSING** Combine ½ T. sugar, 1 c. cold buttermilk, ½ t. mustard, ¼ T. lemon juice or vinegar, and ¼ t. salt.

**BUTTERMILK VEGETABLE SOUP** Slice 2 medium-sized cooked potatoes. Chop 3 green onions (the white part very fine, the green part not so). Mix with 1 qt. churned buttermilk. Add salt and pepper to taste. Heat to the serving temperature and serve (don’t boil it). You can use big onions instead of the green ones by chopping and pre-frying them. Bacon bits are good, too.

**BUTTERMILK RAISIN SOUP** Moisten 1 T. flour with 1 T. buttermilk, and heat 1 qt. buttermilk to scalding temperature. Add the flour and beat with your eggbeater until it is well-distributed. Add ½ c. seedless raisins, 1 stick of cinnamon, and a pinch of salt. Cook until the raisins are puffed. When it’s ready to serve, add sweetening and ⅛ c. heavy cream, whipped.

**BUTTERMILK PORRIDGE** Boil ½ c. barley slowly in 3 c. water for about 2 hours. Add ⅛ qt. buttermilk, stirring until it boils, cook a few minutes, then add ½ t. salt. Serve with syrup or other sweetening.

**BUTTERMILK BISCUITS** From Ruth Brant, Stayton, OR: Combine 2 c. flour, 2 t. baking powder, 1 T. sugar, salt to taste, and 1 c. buttermilk. Mix, roll out, cut. Let stand 15 minutes. Bake 12 minutes in a 450–500° F oven.

**BUTTERMILK WAFFLES** Sift together 2 c. flour, 2 t. baking powder, ½ t. salt, ½ t. baking soda, and 3 T. sugar. Combine 2 beaten egg yolks, 2 c. buttermilk, and ¼ c. melted butter. Add liquid to dry ingredients and beat well. Fold in the 2 stiffly beaten egg whites and bake on your waffle iron.

**Ice Cream**

The old-time name for ice cream was “cream.” Old recipes usually contained lots of cream and eggs. It was considered a confection and was manufactured by the same people who made bonbons. If you like to make ice cream, you’d love Ben & Jerry’s Homemade Ice Cream & Dessert Book by Ben Cohen and Jerry Greenfield.

**INGREDIENTS**

**The Cream.** If you get a buttery taste it may be either that the cream was overwhipped or that it is too rich in butterfat. You can fix that simply by using a more thorough skimming so the cream won’t be quite so rich. It is better not to use absolutely fresh cream. Good cream will double in bulk while freezing.

**Fruit.** Fresh fruit for frozen desserts should be very ripe. If it doesn’t seem ripe enough, cook with a little water. A fruit “puree” in a recipe could be cooked fruit put through a sieve or raw fruit grated or pulped, as with the ripe fleshy fruits like apricots and strawberries.

**Ingredients for Lightness.** Refrigerator ice creams usually contain whipped cream and/or beaten egg white to give them their lightness. Crank freezer ice creams gain a light consistency from the cranking process.

**The Freezing:** Ice cream can be made in your refrigerator’s freezer compartment or in a crank freezer. The stirring breaks up ice crystals and improves the texture. “Refrigerator” ice cream contains so much cream, eggs, and/or gelatin that ice crystals and texture aren’t a problem. But even if the dessert is to be frozen in the refrigerator or freezer, it helps to remove it when it is at the mushy stage, put it in a chilled bowl, and beat it vigorously. A second beating later on would improve it even more.

**In a Refrigerator.** In the freezing compartment the amount of time needed to freeze depends on the mixture, its depth, and the refrigerator; the average time is around 2 hours. The temperature should be under 20°F. It helps to use cold ingredients and to chill the mixture well before putting it in the freezer. Don’t try to make ice cubes at the same time. The sweeter the mixture the more difficult it will be to freeze. It’s best to freeze at the coldest setting you have—the quicker the desserts freeze the better they hold their lightness. But after freezing is accomplished they are improved by resting to mellow for a couple of hours. It helps the flavor and the texture.

**In a Crank Freezer:** If you buy a crank freezer (Lehman Hardware sells them), directions will come with it. The crank freezer will consist of a wooden or metal bucket that holds the ice-and-salt freezing mixture and a nonrusting metal can with a tight-fitting lid for holding the cream to be frozen. The ice cream is stirred by a paddle inside the can, which is turned by a crank on the outside—or in some
cases by an electric motor.

You usually need about 12 lb. of ice for a batch. You could freeze milk cartons full of water in your freezer and then dump out the ice into a bag and pound it to chips with a wooden mallet. You need rock salt, too, for the freezer. The recommended proportions vary. Usually you can use just 1 part rock salt to 8 parts crushed ice during the freezing process. Alternate layers of ice and salt to a point higher than where your ice cream will be in the can. After freezing the ice cream you can repack it for mellowing—use 4 parts ice to 1 part rock salt. Then cover the freezer with newspapers or a piece of rug. In winter you could use snow instead of ice. If the salt doesn’t act rapidly enough on it, add a cup of cold water.

But I never bother mellowing our homemade ice cream. The children are so anxious and it tastes fine enough to me when it’s first done. I don’t worry about measuring proportions of salt and ice either. I just pour in ice and then pour on salt. The can shouldn’t be more than two-thirds full. Turn the crank slowly at first until the ice cream is mush, then more rapidly until it is too stiff to turn. You might want to take off the lid occasionally to scrape the harder ice cream off the sides of the can and back into the middle. Be careful to wipe off the top of the freezer can each time you open it, since even a little of the rock-salt brine getting in could spoil your batch. If your recipe contains nuts or fruit, it will work better if you don’t add them until the mixture is mush.

**STORING ICE CREAM:** A good temperature is 0°F. Use it within 2 weeks. Don’t let it thaw and then try to refreeze because it will get hard and not be nearly as nice. To keep your ice cream, repack it in nonmetal containers; it deteriorates very rapidly in metallic ones.

**BPO ICE CREAM** My favorite for big occasions is a mixture of 1 mashed ripe banana, 1 c. crushed pineapple, and 1 orange (peel and seeds discarded). More fruit makes it better. Stir in maybe ½ c. honey, if the fruit needs it. Then I fold in 1 c. of cream that has been whipped into the fruit mix. More of that doesn’t hurt either. This really doesn’t make very much. I usually double it.

**VANILLA ICE CREAM** Here’s the family recipe for vanilla ice cream from Margaret Kerrick, West Roxbury, MA: Mix 1 qt. light cream, 1½ T. vanilla, and ¾ c. sugar. First put the cream mixture into the freezer can, set the can in the freezer, adjust the top, and fill in around the can with ice and rock salt in layers. Use 3 parts of ice to 1 of rock salt. Then turn the handle of the crank, slowly at first, then faster as it begins to freeze. This makes for a smoother ice cream. When you feel that it is becoming harder to turn, you can open it up and see if it is done. Then you can lick the paddle. Pull it out and gather around with spoons and dig in. If there isn’t enough for everyone to have a taste from the paddle, let them eat from the freezer.

We always made the ice cream before we went to church. After we had our licks, my father packed it, poured off the water from the melting ice, added fresh ice and salt and covered the freezer with a burlap bag with the remains of the ice in it. Then after we came home from church and had our dinner, we unpacked the freezer and ate huge dishes of ice cream.”

**FRUIT MOUSSE** Whip 2 c. heavy cream. Combine with 1 c. of any pulped fruit. Add a trace of vanilla, sweeten if needed, and freeze.

**ICE CREAM SANDWICHES** Between thin slices of devil’s food cake (or whatever you like) place a serving of vanilla ice cream (or whatever you like). You can make your own paper cases and store them in the freezer.

**NEAPOLITAN ICE CREAM** Pack a mold in salt and ice or have ready a mold to go into your freezer. You’ll need to have ready your 3 preferred varieties. Strawberry, vanilla, and chocolate are traditional, but you can vary that. Spread the first variety of ice cream smoothly over the bottom. If it is not very firm, cover, and let it freeze a few minutes. Then spread a thick layer of the next variety on it. As soon as this hardens, spread over the last kind. Cover and freeze.

**APPLESAUCE ICE CREAM** Combine 1 c. applesauce, a pinch of cinnamon, a pinch of nutmeg, 1 t. melted butter, and 2 t. lemon juice. Chill. Fold in 1 c. whipped cream and toasted flaked coconut or chopped nuts, if you want it extra rich, and freeze until firm.

**MILK SHAKE** Mash fruit, fresh or frozen, such as strawberries. Add ice cream and some milk and continue mashing. Add more milk and mix gradually until your milk shake is thinned as much as you like it.

**LOW-FAT ICE CREAM** From Oregon State University, via “Gertrude”: “Dissolve 1 T. plain gelatin and 1½ c. sugar in 1 qt. warm water and bring to a light boil. Cool to 100–110°F. Add 1 c. instant nonfat dry milk and mix well. Chill mix to below 40°F. Add 3 c. chilled whipping cream. Pour all into freezer tub. Add 2 T. vanilla. Stir and freeze in ice cream maker until desired firmness is acquired. It will be ½ gal. to start. Should make, with air added in the freezing, nearly 1 gal. ice cream.”

**FROZEN YOGURT** From Phyllis Vallette, spouse of a Wycliffe Bible Translator, Djibo, Burkina Faso. “You tell in the yogurt section how to serve frozen yogurt with fruit. I wish you had a cross reference to it in the ice cream section. For us it fills the same function as ice cream, but is easier, cheaper and less rich. I make a nice ‘ice cream’ of yogurt and...
guava sauce, about 50-50, sweetened to taste. When I'm not in Africa I do the same with apple sauce (cinnamon optional). For some reason yogurt seems to freeze smooth without long ice crystals, and I don't bother to mush it up at the halfway point."

**HOMEMADE SNOW CONES** My neighbor Kay Morey, a very dear friend who has dug me out of many a hole, gathers clean snow and packs it into cups. She pours fruit juice or syrup over this, and the children love it.

I used to think that bottle-fed animals would just naturally be the most gentle and manageable for their humans. I was so wrong. After numerous tragic farm incidents of injury by animals, veterinary researchers now say this: For males you plan to keep for breeding and for females of large species, use natural nursing by the animals' own mothers or adoption by goats, another cow, or other mammal. Bottle-fed males and females of all species think people are their species, and later, when they're old enough to mate and show instinctive dominance behavior, they may harm a person. An animal raised by another animal ends up being safer to have around people than a bottle-fed one!

But two other old principles are still true: Be gentle and kind to your animals, and be patient. Don't force a bottle into the mouth if you can help it. Don't drag or carry the animals if you can help it. Take the time to coax and teach good habits. Make your animals respect you, and don't ever let one win a battle if you can help it, because you don't want them to think that it's possible.

A goat or cow with good manners, who has friendly feelings toward human beings and is well-trained in what is expected is worth the top price. An angry (mean) animal that won't cooperate is a cull and is worth only the bottom price—to say nothing of all the grief it's going to cause you.

The principles you live by shape the outcomes of your life. Principles, definitions, and measures can be applied to human beings as much as to elements in a laboratory. How do you define yourself? What do you measure yourself by? A lot of how well you do in life depends on the wholesomeness, soundness, and success of your own standards and design for your life—and your self-applied definitions and measures. If you have been defining yourself in one way for a long time and then are suddenly forced to change your self-definition, it's hard.

I went through several major changes in the 24 years since I began this book, including separation and divorce from my husband Mike after 18 years of marriage. I had to change from defining and measuring myself as Mike's wife and the mother of his children. I learned that in every ending there is also a beginning—small and curled up, like the promise of a flower's bud—that must be sought out and nurtured. I learned how to let go when you have to, even if that means letting go of a lot of your self-definition, hanging loose for a while, and waiting to see what your new self is going to be. A major change of self-definition like that leaves you like a child, born—reborn—new into the world. You need time to grow and gradually become acquainted with your (new) identity. I had to do that after Mike left: slowly discover who I was going to be without him, gradually learn that I could be okay without him.

Nine years after that divorce, 9 years spent devoted to doing the best job I could of raising our 7 children, and that task is almost over too. I can look back on both being a wife and being a mother with a clean conscience, for in both cases I honestly gave all I had, my very best every day, for all those years. Now a new time of redefinition, remeasuring, is upon me. Within a few more months the 2 youngest children will be off to college, and I'll be alone in a whole new sense. I won't be a "mother" in the old occupational way any more. It's an exciting next transition.

As with the divorce, at first I was horribly depressed about this and cried a lot. But then I shook myself out of that and realized I was entering a whole new era of exciting options I didn't have before. The kids are all going to be fine without me. Totally unencumbered now for the first time in 30 years, suddenly I can plan to travel freely, visiting old friends and making new ones. I'll be free to research new books where I choose, as I choose. I'll be free to join a club, or clubs, take up hobbies . . .

With nobody needing me at home, I'll be free to spend more evenings out at various interesting events than I spend at home. I've already made myself free enough to devote some effort and money to a major improvement in my appearance, freely answered an ad in the personals that intrigued me, freely chose to accept a dinner invitation from a handsome gentleman . . .

When other people demand their freedom, by default you get yours back too!

INTRODUCTION ........................................... 792

BEES ....................................................... 792

LEARNING TO BEEKEEP .................................... 793
Make Sure You Ask and Learn • Clubs • Bee Books • Magazines • Beekeeping Supplies

ABOUT BEE STINGS ....................................... 794
Of Bees and “Bees” • Bee Breeds • African Bees

GETTING STARTED ...................................... 796
Siting the Hives • Bee/Equipment Inspection • Moving a Hive • Getting Bees

PROTECTIVE CLOTHING ................................ 797
Homemade Beekeeper’s Costume • Store-Bought Beekeeper’s Costume

EQUIPMENT ............................................... 798
Basic Beekeeping Equipment • Bee-Go-Away Items • Parts of a Hive

WORKING WITH YOUR BEES ............................ 800
When You Look at a Frame • Going into the Hive

WATER AND FOOD ....................................... 800
Water • Bee Food • Dealing with Swarming

BEE DISEASES, PARASITES, AND PESTS ............ 802
Basic Bee Hygiene • Brood Diseases • Adult Bee Diseases • Other Pests

HARVESTING THE HONEY ............................... 804
WHEN TO HARVEST? ..................................... 804
Comb Honey • Uncapping the Comb • Machine Extracting • Hand Extracting • Wax in the Honey • Cleaning Beeswax for Candles

STORING HONEY ......................................... 805
Crystallized (“Granulated”) Honey • Other Bee Products

USING HONEY ............................................. 805
Honey at the Table • Cooking with Honey • Preserving with Honey • Baking with Honey • Other Honey Recipes

RABBIT ..................................................... 807
GETTING STARTED ...................................... 807
Magazines • Books • Rabbitry Suppliers • Vocabulary • Buying Starter Stock

RABBIT BREEDS ......................................... 808
Of Rabbits and Pedigrees • Meat Breeds • Rabbit Sizes • Show Breeds • Angoras, the Wool Breed

HOUSING ................................................... 809
Of Rabbits and Heat • Predator Protection • House Rabbits • Rabbit Runs • Rabbits in Cages • Outdoor Hutch • All-Wire Cages

WATER ....................................................... 811
Hot Weather • Cold Weather • Water Containers

FOOD ......................................................... 811
Feeders • How Much Feed? • Controlled Feed Amounts • Pellets-Only Diet • Hay and Grain Diet • Home-Grown Rabbit Food • Salt • “Bones” and “Toys”

RABBIT REPRODUCTION ................................ 814
Sexing • Bucks • Breeding • Maternity Cage • Kindling Management Day by Day • Orphans

RABBIT "VETTING" ...................................... 816
Handling • Nail Clipping • Giving Medicine by Mouth • Taking a Rabbit’s Temperature • Usually Noncontagious Conditions • Parasites

RABBIT BUTCHERING ................................. 818
Killing • Hanging • Skinning • Cleaning ("Dressing") • Cutting It Up • Freezing • Cooking

SHEEP ....................................................... 820
GETTING STARTED ...................................... 821
Books • Supplies • Breeds of Sheep • Where to Buy • Number of Sheep • Age of Sheep • Transporting Sheep

FOODS AND FEEDING ................................... 824
Pasture • Water and Salt • Winter Feeding • Summer Supplements

HOUSING AND FENCING ............................... 825
Housing • Hay Rack and Grain Trough • Manure • Of Predators, Problems, and Fencing

REPRODUCTION ......................................... 826
The Ewes • The Ram • Pregnancy and Lambing • Lambing Checklist • Bum Lambs • Lamb Marketing

SHEEP VETTING .......................................... 829
Tail Docking • Castrating • Parasites and Diseases

WOOL: SHEARING TO SPINNING ..................... 829
Why Shear? • When?

WHO WILL SHEAR? ..................................... 830
Hire a Professional • Do It Yourself

HOW TO SHEAR ......................................... 830

WOOL ....................................................... 831
Wool Marketing • Of Wool and Market Lambs • Cleaning a Fleece • Wool Carding • Making a Wool Quilt • Felting • Spinning and Weaving • Suppliers in U.S. • Suppliers Outside of U.S. • More Fiber Info

SHEEP BUTCHERING ................................. 833
KILLING A SHEEP ....................................... 833
SKINNING A SHEEP ..................................... 834
The Fell • “Fisting” • The Pelt • Cutting Off the Front Feet • Horizontal Method • Suspended Skinning Method

GUTTING A SHEEP ....................................... 834
Preparation • The Gutting
January 1994. Today I’m writing the last page for the ninth edition of this book. It’s a funny feeling. I’ve been working on this book for 24 years—and it’s finally finished. So many years have passed since I wrote the table of contents (which is still basically the same) . . . It’s taken me this long to get it right. But I always had the same dream: to create a one-volume reference work in the field of family food production that would tell people how to grow every kind of food, every step of the way, and would include all the logical supporting information.

There are now almost a million words between these two covers, and that’s just huge. I wanted to create a book so fundamental, so complete, and so dependable that it would be considered essential to have in every home, whether in the city or country. I wanted to make the book as reliable, standard, and useful as a dictionary.

Was it really God who was speaking to me, wanting me to write this book? I’ll never know for sure. The older I get, the more I know I don’t know, and the less I take for granted. Maybe it was something deep inside me, something I had to make happen to meet my own personal needs. That’s the theory I find most convincing. Or maybe I’m just the kind of person who sees a need, envisions a way to meet it, and accepts fulfilling that need as their personal responsibility and life’s duty.

At the time that I made my lifelong commitment to completing this book, I felt that God was responsible for the thought that kept coming to me, insisting that I should and could accomplish this task. There were two reasons I thought this: because our church’s minister and my friends in the church told me that a thought that keeps returning is from the Lord, and because I couldn’t see any earthly way I could do something so clearly impossible. Now I’m much more sophisticated, and I understand that a person can have a strong inner urging that expresses itself in a repeated thought, an urging that is simply a personal mechanism for achieving a personal goal. I know I do have another agenda that this book serves; this book is not my final task. With luck, and God willing, I’ll get to the ultimate finish line.

This latest edition has some unique contents. It presents the latest, safest USDA-approved canning instructions and extension-approved canning recipes for every sort of food and pickle—the updated methods the USDA issued after researchers discovered that all the old canning instructions had problems. Other material that’s unique or hard to find elsewhere includes the detailed, accurate growing information about wild rice and Asian rice; the very complete procedures for harvesting grain without using any machines or petroleum products; the directions for having a baby if you’re all by yourself; the instructions for training a team of oxen; and the procedures to follow if your child eats something that looks like a mushroom but isn’t one. Also, this new edition tells how E. coli can get into a fast-food hamburger and how to make sure a restaurant hamburger is safe for your child if you go out to eat. It tells how to cope with a changing climate and where not to build a house. And more: It provides herb-growing instructions and recipes; how to make quince seed hand lotion; how to turn your garden snails into your supper; how to cure olives; and which simple kitchen item, if mixed with water, will kill and/or drive off even African bees.

Which brings me back to business here: the subject of beekeeping. Read on . . .

Bees

If you are buying honey rather than producing it, try to get it wholesale, direct from the beekeeper. Buy it by the 5-gal. pail. You’ll save money, and that amount will probably be a whole year’s supply for an average family. If you want to produce your own, read on. I hope to have lots of honey this summer. I even have a batch of bees living 2 feet away from the back door, in an old refrigerator that used to be a smoker. It’s a beehive now since they moved in. I kind of enjoy their neighborly buzzing. But I’ve had high hopes before, and sometimes they get dashed. Beekeeping is a very special sort of livestock-raising, and getting your bees to produce isn’t all that easy. It’s easiest if you have a long flowering season and mild winters, and definitely no drought that keeps the flowers from blooming. A severe winter, a dry summer, an epidemic of some unfortunate bee disease—and they can all die on you. Even if you do get started with bees, figure that they probably won’t be able to spare you a significant amount of honey until the third year. That allows them 1 year to get going and you 1 year to make mistakes. Without mistakes, you’ll be there by the second year. Bees are essential to agriculture and to flowering plant life in general because of their function as pollinators. Beekeeping for a living can be an economic roller coaster, even worse than the usual for farming. Professional beekeepers have to study their small subjects for years—their biology and the plants they can gather food from—plus learn how to market their product. But beekeepers have less control over market prices, weather (drought, extended rain and flood, prolonged freezing), neighbors who spray pesticides that kill bees, or sudden onslaughts of disease or parasites in the colony.

There are rewards, too. If you learn what to do and pay close enough attention to your bees so you can do what needs to be done, they’ll provide the sweetest of all foods—and do so at a bargain—as well as produce a crop that there’s always a good-paying market for! You’ll be welcomed into the very exclusive ranks of local beekeepers and have lots to tell as well as ask about at their meetings. You can keep a few bees because they’re interesting and you want honey for your own family, and, if you’re lucky, you’ll still have some to give away: Raise 1–12 colonies.

In a temperate zone, with your still-limited experience, you should count on only 1 or 2 gal. of honey per hive per summer—though with practice and luck you’ll come up to the average of 4–5 gal. Then you could keep more hives and sell surplus honey for a side income—say from 12 on up to 200 hives. Or you could go into beekeeping as a full-time occupation, in which case you’d expect to handle enormous quantities of bees and make all your living at it. Kim Flottum, editor of Bee Culture (who very
helpfully reviewed this section, corrected my errors, and added important new information; I am truly grateful to him!), advised, "You need about 700 to 1,000 colonies to make a living full-time." A pro beekeeper who lives in a prime beekeeping area may average as much as 200 lb. of honey harvest per colony, but the national average is less than 50 lb. per colony. With bees, the uncertainties of harvest are greater than with most other crops.

The commercial beekeeper has to produce as much honey as possible with the least possible expense and then sell that honey for the highest possible price. Beekeeping on this scale is very hard work. Before setting out to sell honey, find out what the local, current regulations are. And you'll have to plan for what containers you'll package it in. You can probably sell wholesale or to retail stores. If you live on a well-traveled highway, a produce stand is a means to sell your honey at a maximum profit.

There are about 150,000 beekeepers in the United States. They keep about 3,000,000 honeybee colonies. They keep bees as a hobby or as a profit-making business, selling honey, pollen, beeswax, propolis, or royal jelly—or bees. They may rent bees for pollination service or move their hives onto land in summer in exchange for a share of the honey. It’s possible but very, very rare to find a self-contained operation in which the beekeeper plants the crop (such as rapeseed) that the bees will make honey from. Beekeepers, even more than most farmers, need to network and stay informed about the ever-evolving bee diseases and parasites and matters relating to African honeybees, as well as new types of equipment, marketing opportunities, and regulations. If you’re a newcomer to beekeeping, you have even more work ahead of you.

Learning to Beekeep

Raising bees is a lot trickier than the manuals make it out to be, and I speak from sad experience. My general impression is that people usually expect more honey than they actually get. Maybe in the South it’s better, but in these more northern climates it takes a couple years—at least—to get built up to where your bees will be keeping you in honey. Above all, you can’t just install and then ignore this tiny livestock. Professional beekeepers visit their bees at least every 3 weeks to check for signs of trouble.

Of all the subjects in this book, beekeeping is the one I feel is hardest to learn from a book—mine or anybody else’s. You really need to learn it in person. So try to find a local beekeeper who will let you visit, take you through a hive, and show you the workshop where hives are made and how extracting is done. Watch the technique. Learn to see and recognize the different kinds of cells and bees. You’ll catch the professional beekeeper’s calm. If a pro gets stung, he or she takes a half minute out (or maybe not even that) to cuss and then proceeds with the job. You’ll need to learn a bunch of facts and procedures . . .

MAKE SURE YOU ASK AND LEARN:

1. What is the organization of brood and honey?
2. What does each type of bee look like (queen, drone, worker)?
3. What does each type of bee cell in the frame look like?
4. How do you find the queen?
5. What do the eggs and larvae look like?
6. Where and how is the honey stored?
7. How does the system of movable frames work?
8. How do you use a smoker to quiet the bees?
9. What other types of equipment does a beekeeper use?
10. How do you check the strength of your colonies?
11. How do you clean dead bees and debris out of the hives?
12. How do you make sure the queen is okay and laying well in the spring?
13. How do you add supers (the upper hive compartments in which your bees will store honey)?
14. How can you minimize swarming (which would halve the size of your colony)?
regularly updated by editors at the A.I. Root Co. (120 pg, $7.99), are a good place to begin. This is where Kim Flottum works, editing current editions of the famous Root publications for beekeepers. (Kim helped me with this bee section.) Kim also recommends The Beekeeper’s Handbook by Sammataro and Avitabile (1988), and says that Hive Management (1989) and A Practical Guide to Beekeeping by Dick Bonney (1993) are also good. Other useful books are The Complete Guide to Beekeeping by Roger A. Morse (1980, reissued 1994), the How-to-Do-It Book of Beekeeping by Richard Taylor (1984, reissued 1994), Beekeeping for Gardeners by Richard Taylor (1982), How to Keep Bees and Sell Honey by Walter T. Kelly (1991), and the Guide to Bees and Honey by Ted Hooper (1976). Sue Hubble wrote two fun anecdotal bee books. Also, Plants and Beekeeping, by F. N. Howes (1979), covers forage plants for bees. Also check out Beekeeping: A Complete Owner’s Manual (1986), a user-friendly book by Werner Melzer, a German expert who presents the European bee scene. The Honey Bee: A Guide for Beekeepers, by V. R. Vickery, a Canadian, reads like a textbook but is up-to-date and thorough. The Hive & the Honey Bee, newly revised and enlarged (1,324 pages!), edited by Joe Graham and published by Dadant, is encyclopedically complete, including history, anatomy, hive styles, etc. Also check out Bees and Beekeeping: A Year in the Life of an Apiary, by Keith S. Delaphane. The Beekeepers Handbook (1998), by Diana Sammataro, Alphone Avitabile, and Roger Morse, covers the life history and behavior of bees, bee management, disease control, and honey removal and processing.

**Magazines**

American Bee Journal is an excellent monthly, $20.95/year, from Dadant and Sons. Free sample copy; 217-847-3324; fax 217-847-3660; 51 S. 2nd St., Hamilton, IL 62341; abj@dadant.com; www.dadant.com/journal. APIS is an entomology newsletter, now out of print, but archived on the web at APIS.ifas.ufl.edu. The new configuration of the API newsletter is found at groups.yahoo.com/group/API_newsletter.

**Bee Culture:** The Magazine of American Beekeeping appears monthly. They offer a free sample. Also, “Who’s Who in Apiculture,” a list of bee organizations and government bee specialists, is published every May in Bee Culture and available at www.airoot.com. (Then click on Beekeeping.) It’s $21.50/yr from the A.I. Root Co.: 216-725-6677; 800-289-7668; 623 West Liberty Street, PO Box 706, Medina, OH 44258-0706, beekeeping@beeculture.com.

**Bee World**, the Journal of Apicultural Research, and Apicultural Abstracts, are all published by the International Bee Research Ass’n: international tel. 44 2920 372409; international fax 44 2920 665522; 18 North Rd., Cardiff CF10 3DT, UNITED KINGDOM; info@ibra.org.uk; www.ibra.org.uk.

Canadian Beekeeping offers news, interviews, features, and ads, both in the text version and on the website where there are also current and back issue samples; $21.40 in Canada; $20 in U.S.: 905-936-4975; Box 678, Tottenham, Ontario, CANADA LOG 1W0; editor@canadianbeekeeping.com; www.canadianbeekeeping.com.

**New Zealand Beekeeper** comes from the National Beekeepers Ass’n of New Zealand; 11 issues per year (Feb.–Dec.). Overseas air mail costs U.S. $38; ship $31: 07-838-2589; fax 07-838-2960; PO Box 447, Hamilton, NEW ZEALAND; magazine@nba.org.nz; www.nba.org.nz.

The Speddy Bee, “The Beekeeper’s Newspaper,” is a monthly for $17.25/year. Free sample copy is available from Troy Fore, Jr.: 912-427-4018; PO Box 1317, Jesup, GA 31598-1317.

**Beekeeping Supplies**

Blossomland Supply sells both beekeeping and candle-making supplies: 616-473-3917; 800-637-5262; PO Box 74, Berrien Center, MI 49102; katherine@blossomland.com; www.blossomland.com.

Brushy Mountain Bee Farm offers a free 84-pg catalog of beekeeping equipment and supplies, protective clothing, candle- and soap-making supplies, books, beekeeping videos, etc.: 800-233-7929 or 336-921-3640; fax 336-921-2681; 610 Bathy Church Rd., Moravian Falls, NC 28654; www.beeequipment.com.

Dadant is the largest bee equipment supplier. Ask for their dealer subsidiary in your area: 800-637-7468; 51 S. 2nd St., Hamilton, IL 62341; dadant@dadant.com; www.dadant.com.

Mann Lake Ltd. offers a free 84-pg catalog of beekeeping and candle-making supplies: 800-880-7694; fax 218-675-6165; 501 S. 1st St. Hackensack, MN 56452; beekeeper@mannlakeltl.com; www.mannlakeltl.com.

Rossman Apiaries sells supplies for beekeepers, including package bees: 800-333-7677; PO Box 905, Moultrie, GA 31776; rossman@surfsoouth.com; www.gabees.com.

Western Bee Supplies manufactures and sells a full line of bee equipment. Order online, or request a catalog: 800-548-8440 or 406-883-2918; PO Box 190, Polson, MT 59860; www.westernbee.com.

**About Bee Stings**

The notion that you can work with bees and never get stung is a kind of romantic fiction perpetrated by bee handlers for fun. Two beekeepers in the presence of an innocent have a traditional conversation that goes like this: First beekeeper: “Have you ever been stung?” Second beekeeper: “No, never. Have you?” First beekeeper: “Never.”

The fact is that even with the best preparation, you’re almost certain to get stung about once for every trip to the beehives you make — and much more if you aren’t wearing the right kind of bee costume. Some people get almost immune to the stings, and then the stings don’t bother them much more than a mosquito bite.

But suddenly that can reverse. Some people, even after years of beekeeping, become allergic to bee stings. Benadryl is a treatment for this allergic reaction, but Benadryl by mouth can’t solve a severe crisis. It doesn’t get absorbed in time. You need a shot. If you have a severe allergic reaction, you can die within 20 minutes of the sting. If you suspect an allergic reaction, head to the closest hospital right away!

Three steps toward prevention: First, if you’re considering beekeeping, get tested for allergies to bees or bee stings. If you’re allergic, obviously you want to take up a
different hobby or occupation. Next, wear your protective costume, especially around your head and neck, which are the most dangerous places to get stung, and don't get any more stings than you can help. Finally, work together with somebody else so that if one of you gets sick, the other can drive; a person in anaphylactic shock is confused (lack of blood to the brain!), very sick, and not fit to drive.

Kim's clarification: "A 'sting' is the organ (pointed) that enters the skin. A 'stinger' is the insect inserting the sting." Okay. So the place where a bee stung you itches like crazy because of the sting in it, which is full of venom. If stung, scrape the sting out quickly with your fingernail or a hive tool. Honeybees are good guys (girls?). They don't usually sting unless you are actually opening up the hive, moving around the frames, and harvesting honey. If you are merely peacefully watching bees come and go in their doorway, there's very little chance of being stung.

**OF BEES AND “BEES”**: So, first of all, please clearly distinguish between honey-making bees and the yellow jacket/wasp/hornet tribes. It really isn't correct or fair to call African in outcome. A true African-domestic hybrid just doesn't exist. The Africans are another race of honey-bee heredity do not travel out of the area. It would be a good idea to also do annual hive inspection for genetic infection, and annual requeening from a source of guaranteed pure honeybee line. All this means a higher level of expertise, though. The current practice is that, in addition to stop importing queens and bees from southern areas, every spring thousands and thousands of bee colonies are moved north for the pollination season. Some Canadian bee experts advise northern beekeepers that their self-defense against Africans is to stop importing queens and bees from southern areas, instead sticking to their own, or other safe northern, stock— or keeping queens alive over winter so the keepers won't need to buy new ones. This would be difficult to implement, though. The current practice is that, in addition to the mail-order queen-and-bee-package business from southern suppliers, every spring thousands and thousands of bee colonies are moved north for the pollination season.

**BEE BREEDS**: In North America alone there are more than 3,500 species of wild bees. They are helpful for pollinating, but they don't store honey at all. There are only 3 basic "races" of bees that beekeepers choose among: the "Italian," the "Caucasian," and the "Carniolan." The Italian bees are yellow and black, hardworking, and don't like their hive opened on a rainy day. Caucasians are considered to be less likely to sting than Italians. Carniolans are said to be the gentlest kind of all. You can also buy a hybrid queen, a cross of 2, or even a cross of all 3.

**AFRICAN BEES**: The Africans are another race of honey-bee. When they breed with domestic bees, all their aggressive qualities tend to get passed on. Because of this genetic dominance, an African–domestic bee cross equals an African in outcome. A true African-domestic hybrid just doesn't exist.

How aggressive are they? The African bees are some 30 times quicker to take offense than regular bees, sting 10 times as often, and tend to attack en masse, having a stronger chemical system for calling their brethren to the project than do regular honeybees. Having thousands of bees attacking you all at once would be disconcerting, to say the least. Wherever there have been African bees, there have been deaths of people and livestock. They have been steadily migrating northward since the origins escaped from a research lab in Argentina. The African bees have made it north to Texas, New Mexico, Arizona, and California. They are expected to ultimately spread throughout the southern third of the United States but no farther north than that.

If African bees move into your neighborhood, you'll find out suddenly and traumatically as you're being chased down the road. Incidentally, the first line of defense against African bees is running away. If you can run 15 miles per hour for 5-7 minutes, you can get away from them. (That's 8-10 city blocks.)

If you encounter a nest or hive of African bees, don't try to be a hero and attack them. Kim Flottum explained to me that if you were to go in there in full bee regalia with a couple cans of Raid, the Raid would accomplish no more than to ensure that thousands of furious and still-healthy bees would attack you within seconds, and significant numbers would succeed. If there is even the slightest flaw in your outfit, say a loose legging, you'll have 200–1,000 stings within seconds. If you encounter a nest of Africans, don't try to eradicate them yourself; call for help from authorities.

There is a silver lining to this. Turns out Africans are vulnerable to something: soapy water. A fire truck loaded with soapy water can wipe out a colony.

NOTE: If a person is being attacked by African bees, spraying them with soapy water helps—it kills the bees. If there are African bees in your area, make a bee bottle (soapy water in a sprayer) part of your basic vehicle, tractor, and picnic pack. Mix 1 c. powdered or liquid detergent per 1 gal. water. Shake it up, and spray. A 2½-gal. Hudson sprayer is good for family-level defense. This has been tested, and it really works.

In this new era we must adapt to African bees as just another of the problems beekeepers have always routinely, and successfully, dealt with. Beekeepers, by definition, are not fearful persons!

**Southern-Area Beekeepers.** Winston predicts that the government will probably eventually be imposing a mandatory quarantine, so that colonies possibly infected with African-bee heredity do not travel out of the area. It would be a good idea to also do annual hive inspection for genetic infection, and annual requeening from a source of guaranteed pure honeybee line. All this means a higher level of training for old-time beekeepers. It also means that "hobby" beekeepers are going to have to be much more expert and involved with their bees than used to be necessary—or they'll have to give it up. Also, in these areas there needs to be a wider distribution of bee-sting kits and information about how to use them.

**Northern Beekeepers.** Some Canadian bee experts advise northern beekeepers that their self-defense against Africans is to stop importing queens and bees from southern areas, instead sticking to their own, or other safe northern, stock— or keeping queens alive over winter so the keepers won't need to buy new ones. This would be difficult to implement, though. The current practice is that, in addition to the mail-order queen-and-bee-package business from southern suppliers, every spring thousands and thousands of bee colonies are moved north for the pollination season.
Getting Started
As with all livestock, it's vital that you have a suitable place for these critters to live.

Siting the Hives: Obey your local zoning regarding beekeeping. And place the bees in such a way that they don't bother your neighbors. Bees, like airplanes, take off and land in front of their hive. This is their flight path, and they guard it. So don't place the bees where their flight path will cross a place where your neighbors are likely to be—their garden, swimming pool, or sidewalk. Bees are also irritated by vibrating noises, so don't place them where somebody will be coming within 10 feet with a lawnmower or similar source of noise. (A.I. Root offers a free pamphlet about beekeeping in residential neighborhoods.) Place them where the early morning sun will reach their hive and stimulate them to get out and find nectar.

It doesn't matter if your own yard is very small or in the city; bees will fly for miles to find appropriate blossoms and will bring back the nectar. But it's not wise to crowd too many bee colonies into a small area. About 25 colonies per "bee yard" is the maximum if you live in the city. In the country, limit it to 60. You don't have to own the land your hives sit on, but you do need to have the permission of the person who does. Most farmers will be agreeable to letting you set your bees on their land in exchange for a share of your honey crop each year.

Bee/Equipment Inspection: State laws vary but it is against the law to sell used equipment for beekeeping in Florida, for example, without a certificate issued by the Florida Apiary Inspection Service. And every Florida beekeeper is required to register with the Florida Department of Agriculture. But some states don't have any inspection service at all and have fewer laws applying to beekeepers. For bee inspection or questions regarding it, contact your state's department of agriculture to get the name of your state apiary inspector, if there is one. He or she will help you contact a local inspector. An inspector is a good person to look over a colony of bees or any used equipment that you're thinking of buying. The bees can be examined for disease; the equipment can be tested for it. Contagious disease is such a huge problem for beekeepers these days. Some states (Washington and Ohio) have very good inspection services; some have none at all. You need to find out what the laws and services are in your particular state. Are the bees you buy going to be inspected where they come from, or after they arrive where you are, or at the border (California)? To sell bees, you want a certificate from an inspector guaranteeing their health. This service sometimes costs (Californians pay for mileage as well as an hourly rate for inspections) and is sometimes free (in Ohio, for example).

Moving a Hive: You could plug up the door of the hive with cloth or grass, but folded window screen stays put more reliably. Be sure to use something that's porous; if you plug it airtight, you'll smother the bees. If the plug comes out while you're moving the bees, you'll have a really, really big problem. Don't let this happen!

Getting Bees: It's easiest to start small (with 1 or 2 hives) and expand gradually. You have to choose and order your bees and choose and order the hive you'll install them in. You can find bee producers from whom to order in any popular bee magazine. Southern or California growers typically supply bees to northerners in the spring or sell "NUCS," which are colonies of about 1,000 bees that have queens that are already laying. Order package bees early, several months before you want them delivered. Orders are filled on a first-come, first-served basis, so if you order too late you may not get any bees at all. You want them delivered at your local fruit-tree blooming time. Package bees won't give you much of a crop the first year because of the low starting population. The alternative, buying a hive together with the bees in it from a neighboring beekeeper, is also best done in the early spring. In fact, I recommend that you start by buying hives from a nearby beekeeper. Then you'll get an already established hive in which everything is going right—one that has lots of workers ready to go and a fine producing queen. Buying from a neighboring beekeeper has another built-in advantage: neighborly advice if something doesn't seem to be going right.

Homemade Hives/Local Bees. Professional beekeepers used to make their own hives, but now they usually assemble them from pieces purchased from suppliers. If you start purchasing from a particular supplier, you may have to stick with him or her because components from one line often won't fit with those from another. So study and shop carefully before your first start-up. If you buy from a neighborly beekeeper, the bees will cost you from $25 to $50. You will have an already established hive in which everything is going right, one that has lots of workers ready to go and a producing queen. You'll probably get the bottom 2 boxes—your brood chambers—and would have to pay extra, around $8-$15 each, for supers. But in these disease-ridden times, you may prefer—or be required—to buy only inspected, certified disease-free bees and equipment.

Mail-Order Start-Up. You can get a good hive going by ordering bees from Montgomery Ward's catalog. But Kim says you're wiser to order from a bee equipment supplier whom you can call and get help from. Ward's won't help you. A 3-lb. package of bees gives you 9,000-10,000 bees—not a bad start!" The hive comes disassembled, and you put it together yourself. Nothing to that. You don't have any finished comb to start with when buying mail-order; that's the drawback. But, given time, good conditions, and good care, mail-order bees will establish themselves and do fine.

Catch-a-Swarm Start. You can't get a hive going just by putting out a hive and hoping to get a swarm to move in. I've tried that too. If you're a beginner, catching a swarm is asking a lot of yourself—not that it's hard, but when you see a swarm of bees and everybody nearby in a panic over them, and you've never handled bees before, it often doesn't seem easy.

Starting Additional Hives. Once you have a start of bees, you can get all the other hives you want off your own bees. An old-time beekeeper would think it foolish to buy more when you could start your own. To start another hive, prepare a brood chamber around May 1. Now go into your best-established hive, the one with the most bees; it will be on the verge of swarming anyway.

Take 4 frames out of that well-established hive. Choose frames that have brood cells (which worker bees will hatch out of), some honey, and some bee bread (pollen), which means cells filled with a sort of yellowish grainy stuff. The frames will almost certainly have some workers crawling
1. Wear white-colored, smooth-surfaced clothing. The more white you wear, the better. White and smooth doesn't irritate bees as much as dark and rough-textured clothing. (Above all, don't arrive in a dark-colored, deep-pile coat, which would for sure set off your bees' instinctive bear alarm!)

2. Make sure all entrances to your body are safely closed off (bees crawl into dark crannies!).

3. If possible, work with your bees during sunny, warm weather near midday, when most are out of the hive harvesting from flowers.

4. Use a smoker to quiet the bees.

5. Raise a gentle breed and take all possible precautions against African bees.

---

**Minimizing Stings**

around on them; if they don't, dump lots of worker bees in there, or scrape them off other frames. The frames will almost certainly have queen cells, too. There is usually at least 1 queen cell per frame if the bees are making queen cells at all. If need be, you can cut one out from a frame and stick it into a new frame. You can start a new hive with every queen cell.

Install the frames in the new hives. Put on the lid and stuff up the entrance loosely with grass to give the bees a chance to feel at home. Then go away and leave the bees alone. The workers will do the rest, including making a queen out of one of the eggs if you didn't give them a queen cell.

---

**Protective Clothing**

You can buy your outfit ready-made or make your own. I recommend the ready-made, which sounds out of character for me. But it's really important to have a good bee costume so you don't have to be nervous. That way you can just go in there and do what you have to do. The worst things that can happen when working with bees are for you to panic or for your nose to itch. A really safe bee costume on a hot day is hot inside. It helps to wear as little underneath as possible. I know a lady beekeeper who goes naked inside hers. It makes her less at risk for heatstroke, and she's not in danger of attack bending over a hive of bees from anything but a bee!

---

**Homemade Beekeeper’s Costume**

**Protecting Hands and Arms.** Wear gloves. Kim advises: “You don't need very thick gloves. Some use rubber gloves. If too thick, you can't pick up frames or manipulate the hive tool.” Gauntlets protect the area over your wrist and forearm. You can make a homemade gauntlet and sew it at the top of the work gloves. Make it long enough to reach high above your elbow, with elastic at the top to hold it firmly on. Use canvas that is thick and stiff and bags out well. The bagging out is your best protection. A favorite spot the bees sting is right at the top of your gauntlet, where the elastic presses them close to your arm. And they'll really try to sting your hands. Getting gloves of even the toughest leather isn't absolute protection. Sometimes they can sting through leather, too. The bees will crawl around on you and keep poking their sting down, trying to hit pay dirt.

**Protecting Feet and Ankles.** Wear work boots or cowboy boots. Both are absolutely beeproof, but work boots are better. Tie your pants tightly to the outside of the boots with a strip of inner-tube rubber or elastic so the bees can't crawl up your legs. Or use the top cut away from an old army combat boot—the canvas wraparound that straps tightly to hold your pant leg close against your boot. Bees crawl up.

They won't just sting you on your ankles if they get in; they'll go way up so fast it'll amaze you. This is the voice of experience talking. Don't assume they can't find the gap; that's really underestimating bees. Early in my beekeeping, I went out to the hives with my pant legs tied down, but I was wearing a winter coat rather than coveralls. I figured that would be good enough. Suddenly they found a way under that coat clear up under my shirt, and I ran all the way back to the house slapping bees. I had about 12 stings around my waist and above it on my back and chest.

**Protecting Your Body.** Wear white, 1-piece, baggy coveralls, complete with gloves, gauntlets, boots, and a firm fastening on your pant legs outside your high footwear to protect your body. If you make the 1-piece, zipper-in-front coverall out of rip-stop nylon, the stuff they make tents from, you'll avoid stings because bees can't get a foothold on it. It's far better than cotton in that regard because cotton has fibers the bees can get into with their feet. And if bees can get their feet dug in, then they can sting.
Protecting Head and Neck. Use a tropical-type helmet (a construction hard hat) or a beeproof straw hat. Whatever type of hat you wear, it should have a firm, wide brim. You'll also need a bee veil, which you can mail-order. The bee veil top fits around the upper brim of your hat. The crown of the helmet fits up through the top hole of the bee veil. You tie it firmly around the crown with a drawstring. Now turn up your inside collar. Tuck your hair inside it. Draw the bottom drawstrings of the veil tight around the base of your collar. Make sure there isn't even a small hole. Then bring down the strings, cross them over, draw them around to your back, cross them there, and bring them on around to your front again, where you tie them firmly. Why? So that when you lean over, your bee helmet doesn't flop off, taking veil and all with it. Wearing all that in hot weather is bad enough.

Order in Which to Put It All On. 1. Coverall. 2. Boots. 3. Elastic to hold pant legs down. 4. Bee helmet and veil. 5. Gloves and gauntlets. (Dishwashing gloves work, too.)

Store-Bought Beekeeper's Costume: These you buy from a beekeepers' supplier. Their bee gloves come equipped with gauntlets. You can buy a white coverall with helmet/bee veil that zips into place around the neck. It's worth the money if you can afford it. They come in all sizes and various styles.

Equipment

New, as opposed to used, bee housing and equipment is expensive, but it helps you understand what the ideal format is. The argument for starting with good stuff is that the lifetime of bee equipment is very long, easily 20 years and possibly 50. The hives should be purchased or built months before your bees are expected, so you'll have plenty of time to be certain they are ready and set up in the planned location before the bees arrive. You have a big problem if you have bees and no hive.

You'll need hive-working equipment such as your bee costume, smoker, and hive tool. Then each following year you can try to upgrade somehow: Increase the number of colonies or improve your efficiency. Or you can buy with an eye to the budget and not buy new equipment but purchase working colonies. Or, if you are a good woodworker, you can make your own hives and purchase package bees or NUCS to populate them. But there's much more to it than this. I haven't the space or personal knowledge to tell you everything you need to know. All I can do is give you a basic orientation and point you in the right direction to get more detailed information.

Basic Beekeeping Equipment: Most beekeeper suppliers have a basic beginner's assortment along these lines.

1. One (or 2) standard 10-frame hives, each with bottom board, entrance reducer, foundation, frames, inner cover, and outer cover.
2. A package of bees, with a queen for each hive.
3. A smoker.
4. A hive tool, which you will use to pry the hive and frames apart when you examine the bees.
5. A bee brush to brush bees off a honey frame when you are getting ready to take it away from the hive.
6. A feeder to feed sugar syrup to your bees until they have enough numbers to gather nectar and enough flowers to gather it from.

Bee-Go-Away Items: These all gently, diplomatically, make bees go away.

Smoker. The smoker has a burning chamber with an attached small bellows that you can pump. A. I. Root says that most beekeepers consider the smoker to be "their most important piece of equipment." The smoker is valuable because the presence of smoke triggers a bee instinct to drop everything else and fill up their honey stomach with honey. That keeps them peacefully busy, quiet, and not paying attention to you. Smoke also interrupts the communication of alarm signals between bees. But there is such a thing as too much smoke. Use only as much as you need.

Start your fire with a piece of crumbled paper, which you light and drop into the smoker's canister. Then add your solid fuel such as pine needles, dry grass, dry wood, wood chips, a piece of burlap bag (not one that has been treated with insecticide, which would kill your bees), corn cobs, or a piece of cotton rag. You want a fuel that will smoke rather than burn fast, so don't use fuels that create high heat in there, as charcoal or chemical fluids would. If you slowly pump the bellows, it will help your fuel get going well. Once your fire is burning, add the rest of your fuel and close the lid. Ideally the active fire will then stop, but your fuel will still be smoldering. Light the fire just before you're ready to go to work on the hives (after your bee costume, except gloves, is on). Even after your fire is started, give the bellows a little pump now and then to keep the fire from going out.

At the hive, stand to one side of the entrance (out of the flight path—bees instinctively react to obstruction of their flight path, especially the last few feet of it before the hive entrance)—and blow some smoke into the entrance. After a minute, take off the hive cover and blow more smoke through the hole in the center of the inner cover—if you use one (many beekeepers don't). Blow more smoke into the hive. Especially before you examine a bee-filled section, waft smoke over the tops of the frames. Then remove frames to look closely at them. Blow the smoke at the bees whenever they seem overly concerned with you rather than being about their own business.

Whenever you need to blow smoke at the bees, slowly pump the bellows. (Pumping too fast gets your smoker fire too hot and would pump out burning ash.) Experience teaches you how to best use your smoker to keep the bees under control.

Bee Brush. You can use the bee brush at honey-harvest time to brush any remaining bees off frames of harvested honeycomb that you want to take to your house. Brush them off gently near the hive entrance so they can easily find their way back home. At all times, avoid pinching or crushing bees when moving frames in and out. An injured bee releases an alarm odor that arouses other bees to sting.

Bee Escape. The bee escape is an inexpensive product that is used to eliminate bees from the honey-laden supers before you harvest them. It's a one-way exit that you can put in; then you come back in 24 hours and harvest your bee-free honey supers.

Bee Go. This trademarked product is sometimes used by beekeepers when they get ready to take the supers for extracting the honey. Directions for use come with the product. It's important not to get any of it on the honey or wax; that would ruin it.
If I were to say much more about your purchase options, I'd just be repeating what the catalogs will tell you.

**PARTS OF A HIVE:** The start-up structure before the bees arrive consists of the floor of the hive (bottom board); the sides of the first box; which are fastened together at the corners somehow; and the top cover. These parts are detachable from each other just by lifting them apart. Inside that box there are "frames." Most beehives are now made to hold 10 frames. There are ridges on the inside of the walls to set the wooden top bars of the frames on the hive box. The frames hang in there at an equal distance apart, all across the inside of the box. Each frame starts out holding a layer of beeswax "comb foundation" onto which the bees build full-scale comb for raising brood or storing honey. The whole thing needs to sit on a "hive stand," which is a platform.

**Hive Stand.** This platform is needed under your beehives if tall grass is interfering with the bees' flight patterns; it's also used to level the hive and keep out ants. If you can help it, don't put hives in the same pasture with horses or cows because sooner or later, one of the big animals will get rambunctious and knock over a hive. If this happens in cold weather and you don't notice right away, you'll have a hive of dead bees. They need the shelter their hive's enclosure provides. Skunks will take bees. They get outside a hive and scratch the front door. As the bees come out, the skunks eat them.

**Brood Chamber.** The bees live in the bottom box, which is usually called a "brood chamber." There the queen stays and lays eggs; most of the cells in there have baby bees in them rather than honey. The next layer up usually ends up being mostly brood cells, too, with maybe some honey around the sides and top. A layer is called a "super." Those 2 bottom boxes are what you get when you buy bees from a beekeeper, and you never want to break up that comb to try to get any honey. Just leave it alone.

**Supers.** The supers are (usually) shallower boxes that you set on top of these bottom 2 brood chambers. They are the ones that the bees store extra honey in. The bees work from the bottom up, and that's why you need more supers in a good honey year and fewer in a bad one. Supers that you buy come in your choice of heights. The deeper ones aren't really desirable because if they do get full of honey, they are almost too heavy to carry. Each super or brood chamber holds 10 parallel frames, hung vertically so that they don't touch the bottom or sides of the box. Bees build beeswax cells on the frame to contain brood, honey, or pollen (bee bread).

**Foundation.** Beekeepers usually buy their comb foundation from a beekeepers' supplier. Foundation is a thin sheet of beeswax already pressed into the 6-sided shape of the bottom of a bee cell. All the bees need to do is build the sides and top (cap). When you put the foundation into the frames, you use wire to support it and add strength. Professional beekeepers have a choice of 2 special tools for heating the wires so they'll easily sink into the foundation. One sends a jolt of electricity through the wire that heats it.

You can make do with nylon fishing string (or even plain string if desperate). Put it through the hole and draw tight. If you don't use wire or string, the foundation will wilt in the summer heat and get out of place. If the foundation is not exactly where it's supposed to be, exactly the correct distance apart from the next layer of foundation, the result will be that you can't raise frames efficiently to look for the queen or queen cells because the frames will get stuck together by the bees where the frames are too close. If you put the foundation in right, the bees will build a neat sheet of cells along each side of the foundation and leave themselves an open-air walkway between each and every frame. That makes it easy for you to pull out an individual frame and look it over. If all goes well, at the end of summer, the frame will be covered with brood cells by the bees in the brood chamber or built into comb in the supers and filled with honey.

Experienced beekeepers may harvest the wax comb, which can be sold profitably in addition to the honey, or they may return it to the bees for refilling with honey. Beginning beekeepers sometimes don't realize that they can't have honey until they have honeycomb. Every day the bees spend making the honeycomb is a day they can't be gathering and making honey. But Kim says that since bees can make comb even faster than honey comes in, there's no delay problem.

If beekeepers choose to reuse the comb, they just slice the end off the chambers and make the honey pour out of the inside by centrifugal force in an extractor. Then they give the comb back to the bees for them to refill.

**Homemade Foundation.** The old-timers used to make their own. In those days the Root Company made rollers for rolling the wax into foundation. Now you can't buy the rollers anywhere that I know of, unless you can find one as
an antique. You can buy the foundation only from various supply companies. The old-time rollers were made of hardwood maple and were carved by hand. The roller has to be carved or built with a hexagonal impression pattern in it; otherwise the bees won't build it into comb. The way the old-timers made the sheets of wax for rolling was by taking an 8- or 10-inch board, dipping it into hot beeswax once or twice, and then letting it cool. When the wax was firm, they slit it on the side and peeled it off. They rolled that with their patterned roller, and that was their foundation. Kim Flottum says it worked okay but was expensive—lots of wax wasted—and slow.

Plastic Comb. This is a 1-piece, frame.foundation, completely drawn plastic honeycomb. Kim wrote, “Plastic foundation is like wax foundation—embossed with the 6-sided cell but made of plastic and coated with wax. The bees draw the cells from the plastic base, fill them with honey, and then cap them with wax. You take these in and out like the regular frame and foundation. They can go into an extractor.”

Working with Your Bees

I know this is inadequate. There's really no substitute for going to the hives with an experienced beekeeper—no matter how well written or illustrated your manual.

When You Look at a Frame: The cells that are capped dark-brown are brood cells. Those are the ones the bees hatch from. The ones that are capped light-colored contain honey. The cells will be in sections of either one or the other. Queen cells are very easy to find, about an inch long, kind of hanging away from the rest of the comb. They look like a peanut shell. Drone cells stick out too but not nearly as much as queen cells. Drone cells stick out like little lumps with bullet-shaped tops. The worker cells are just exactly level with the rest of the comb. In short: the queen cells are the biggest, the drone cells are next in size, and worker cells are the smallest.

The Queen Bee. Before you start moving stuff around, find the queen in the hive—so you'll be sure not to hurt her and you can have her end up where you want her. To do this, pull out frames and look them over carefully one by one until you locate her. She doesn't look like any other bee at all. She's about an inch long and tapers clear from her front to her tail. The other bees will be somewhat spread out away from her. They don't crowd her.

A queen bee might sting you if you grab her, but usually the only stinging she does during her life is directed toward other queen bees. When the first new queen hatches out, she'll go around and sting the others to death right in their cells. There can be only 1 queen in a hive. The drones haven't even got a sting. Only the workers sting you. The drones are big, fat bees with very large eyes. Their only function is to compete with one another on the queen's mating flight and earn the privilege of fathering the new hive offspring. A queen bee is a marvelous creature that can live 7 or 8 years—a long time for an insect! They are really good for only about 3 years, though, and that's why beekeepers talk about “replacing” the queen. Your honey crop depends in part on the vigor of your queen. It takes 21 days for workers to hatch, 16 days for a queen to hatch, and 24 days for a drone to hatch. The more eggs the queen lays, the more workers there are to make honey. But it also depends on the weather.

Queen Excluders. Excluders are made of a wire grid that allows a worker through but is too small for a queen. Kim wrote, “An excluder is used to keep the queen from moving into honey supers and laying eggs. You do not want brood in your honey supers. Excluders should be used for cleanliness and sanitary honey production.” He also told me that excluders can't be used to separate queens because queens can and will sting each other through an excluder.

Going into the Hive: This means to open up the hive and carefully remove and look over every single frame to find the queen, look for queen cells (but only in the spring), and generally assess how many bees there are, how many and what type of brood cells, how much honey is coming, and whether the bee colony needs more supers. You want to give them plenty of supers if they need them because overcrowding leads to swarming. (Sometimes they swarm anyway.) If you're very lucky, you may need 5 or 6 supers by summer's end—but more likely you'll need fewer. It will depend on the hive. Each hive has its own history each summer; there are seldom any 2 just alike.

Get into your bee costume and get your smoker going. Take either a hive tool or a screwdriver. (Kim: “... only if nothing else is available. They really wreck a frame.”) Use it to pry apart the lid from the hive and supers from brood chambers. The nearer you get to the bottom, the harder it will be to get things apart as the comb gets bigger and firmer. You can set the supers on the grass while you are working in the brood chamber. Kim: “Set your cover (top down) down first, and set supers on this. That way if you miss the queen and she falls off, she won't get lost.”

To put a super back on the brood chamber, do it so as to kill no more bees than necessary. Start it at one end and slide the super slowly onto the brood chamber so that you slowly shove the bees that are on the edge off the sides. They'll find their way around to the door again.

Water and Food

Water: The bees should have a nearby source of water. In an urban setting, be sure and provide their water so they don't habituate a neighbor's swimming pool. The water supply should be fresh and running. Stagnant water has been named as a factor in bee disease. Bees bring water in to evaporate and cool their hive in hot weather and to dilute honey for feeding brood. If you don't have a nearby creek, let an outside faucet drip down onto a board set slantwise. If you have a heavily populated hive, the weather is hot, and you see bees clustering outside the hive entrance, they have a heat problem inside beyond what their water-carrying can handle. In southern states, hives are typically placed in half-inch ventilation space.

Bee Food: Shakespeare said, “Where the bee sucks, there suck I.” To me that means honeysuckle. It's a wild vine with pretty trumpet-shaped orange flowers. It grows up the trunks of trees and flowers among their branches. The children love honeysuckle time. To get the nectar, you pick some of the pretty, long, orange flowers when they are fully developed. Pick them with the tiny green bulb on their base intact. Then nip off that green bulb with your fingernail. Put your mouth to the opening you made at the base
of the flower and suck. You will get a tiny taste of nectar. Some honeysuckle flowers have more of it and some less. Nectar is bee food, too. It's the only food they can eat. How much honey your hives yield for harvest is basically a result of how much and what quality of flowering plants were available. But bees are very good at finding, collecting, and storing it!

Bees gather flower nectar and carry it back to their hive, where they change it to honey. They like herb flowers—such as basil, bergamot, borage, catnip, fennel, hyssop, lavender, lemon balm, marigold, marjoram, oregano, rosemary, sage, savory, and thyme. They like almost any fruit blossoms. An orchard is a good place for your hives in the spring—as long as it doesn't get sprayed with pesticide. In southern California, where bee pasture is available nearly year-round, bees can make honey from flowers on the eucalyptus trees or from citrus and other trees that are in flower in winter, like the lemon.

Flower Flavors. Whatever type of flower your bees are gathering nectar from, that's the flavor the honey will have. Buckwheat honey is very dark in color and heavy in flavor. Clover and alfalfa blooms make a light-colored honey of delicate flavor. But if your bees get their honey from wildflowers, carob trees, and oaks, it's likely to be rich, dark honey that the USDA would grade “Number 4”—meaning not fit for human use. Which is simply ridiculous. But commercial standards favor the sort of honey you get from a big sweet clover or alfalfa field, which is pale. “Number 4” is edible, and some people get along fine with weird-tasting honey. Food and gardening writer Lane Morgan says, “I have heard that people with allergies can use honey from the allergen-making plant to lessen their sensitivity. It's sort of a homeopathic treatment.” But she also told me about “cabbage flower honey—which really is pretty much inedible.”

Insecticides. Don't use pesticides yourself. Ask your neighbors not to use them. Even a spot of spray here and there on plants or gardens will kill a few bees. When entire fields and orchards are sprayed or dusted, the resulting loss to a bee colony can be devastating. The beekeeper sees a large accumulation of dead and dying bees at the hive entrances. If spraying is to occur in your area, you need to know about it in advance. If possible, work with the farmer and the pesticide applicator so their efforts will safeguard these valuable pollinating insects. Your risk from spraying comes not only from blossoms on cultivated crops but also orchards, orchard ground covers, and sometimes uncultivated areas such as roadsides.

Ask that insecticides not be applied to open blossoms. Be sure the sprayer knows that the safest time to apply insecticides is late afternoon, after bees stop foraging. (Early-morning applications are less dangerous to bees than those in midday.) Finally, persuade the sprayer to select an insecticide that has the least impact on nontargeted insects and animals.

If you're not successful getting these assurances but you can get a few days' warning of a spraying that you know will harm the bees, move the hives at least 2 miles from the spray area. If notice is short and the spray plane is coming right over your hives, drape them with damp burlap. That protects against a direct hit. Then you'll have to remove it and accept some loss of bees. But if a bee colony is repeatedly exposed to pesticide, there will be fewer and fewer living bees until at last the remaining ones can't survive.

If your bees are suffering due to pesticides or herbicides, tell your beekeepers' association, the state extension agent, the person or business that did it, and the spray inspector if it's a conspicuous wipeout. Kim Flottum wrote that no insurance compensation is available for this. "Don't even try. If you are able to prove neglect, however, you can sue the applicator."

Herbicides. These aren't good for bees either because they tend to kill flowering plants. Public spraying of herbicides around road edges and shorelines to fit some artificial notion of which plants are okay and which are not unnecessarily kills flowering plants that could support bees.

Weather and Climate. Bees gather what they find. They can work only when flowers are in bloom. So they have more chance to gather honey in climates where flowers blossom during more months. In northern climates the heaviest honey flow is usually in June. But a summer so dry the flowers can't grow or don't bloom well is a bad one for bees. I've seen dry summers when the flowers didn't bloom until the fall rains came, and the bees made hardly any surplus honey at all. Southern bee growers have a longer flower season and so tend to get larger honey harvests. In southern California it's not unusual to take as much as 100 lb. of honey from one 10-inch super twice a year. In an exceptional summer or in an exceptional climate (like Hawaii), each of your hives might yield 200 or even 400 lb! An extra-cold, long winter shortens their harvest season and lengthens the time they must live on stored, or owner-supplied, food.

Winter Food. To get your bees through, a colony needs a young queen, a large cluster of adult bees, 50-100 lb. of honey, and a few combs of pollen. They should be in a 2-story standard hive with 1 brood chamber and 1 honey super (the removable top section where the bees store honey). Starvation—not cold—is the biggest risk for your bees! Bees don't hibernate during the winter. They are very much awake inside the hive, clustered in a ball in which they generate heat for each other. But they have to eat all winter long to have the energy to make that warmth, or they'll die. If they get low on honey, you'll have to provide supplementary sugar. Feed them a syrup of 2 parts granulated sugar to 1 part water. You can buy a substitute for pollen from a bee-supply dealer. Feed them that after the honey harvest in the fall, before winter sets in.

As long as there are blossoms, the bees will make honey. Around here they are done with most of their honey-making by the end of August, when everything dries up. That's the time to get the honey. We use 2 brood chambers and 2 supers, taking 1 super for our use and leaving the bottom honey super for the bees to winter on. You have to estimate how much honey they need to winter on—different parts of the country have a longer or shorter cold season—and take only what's surplus beyond that. If the bees don't have enough honey over the winter, they will die of starvation. You'll go out in the spring to look at them and just find a bunch of dried-up little bodies.

So check them in cold weather, too. You won't even need your bee suit. They'll be huddled in the brood chamber trying to keep alive by buzzing to make warmth.

Sugar Feeding. If they seem short of food, dump in a bunch of white sugar. Never, never feed them brown sugar. Dump sugar on an inner cover (not directly into the hive),
between the frames, or onto the outside. They'll survive on it. A dear friend of mine who is an experienced beekeeper told me, "Big honey producers nowadays feed their bees thousands of pounds of sugar every winter to carry them through and also through dry seasons. If you aren't feeding your bees sugar, it takes them a lot longer to accomplish anything." So even under bad flowering conditions, a beekeeper can feed sugar to the bees and have a good honey crop. But honey from sugar-fed bees can be only for home use. If you sell honey made from sugar, you are breaking the law! Commercial beekeepers may feed sugar to build up their bee population to take advantage of the coming nectar flow but not to make honey for sale.

I've been working on this book for over 20 years, and I'm making some major additions or changes now for the eighth time. I tell other authors that I meet, people with a string of fine titles to their credit, "All my life I've written one book." That's generally good for a shared laugh, but there's a bittersweet private sadness to the fact for me. I have indeed come back to this book again and again, trying to make it more thorough and more accurate, and it makes me happy to see it improve. On the other hand, I have written, or tried to write, other books. None of those others have ever yet made it into print. Maybe some day I've tried so hard. I read that a writer needs to write the first million words just for practice. Well, I've accomplished that. In fact, I think I'm somewhere in the second million. The breakthrough should be coming any day now! There's something else I want so much to say.

Dealing with Swarming: This is common in the first half of June here in Idaho, earlier in the south—as early as March! There can be only 1 queen in the hive. If extras hatch out, many of your bees will fly off with the young queen to make a home and a new hive wherever they can; what's left of your hive won't give you much of a crop. If you don't want to start new hives, pinch out all the queen cells to prevent swarming. The more workers populate your hive, the more honey they will bring home. If you go into a hive and find queen cells but no queen, it probably means the old queen swarmed.

Then you'll hear from the neighbors. Sometimes bees move into house walls. They can get between the outside walls or between upper and lower floors. If they do that, don't poison them. Kim Flottum wrote: "You can trap them out using a funnel-shaped screen. The bees can leave a space between walls, etc., but can't return. An empty colony is placed outside and the bees move in. Eventually the old nest is empty, and you can then fill in the entrance solid so it can't happen again."

There's really no way to determine who owns the bees after they've left the hive, but once you've acquired a reputation as a beekeeper, the phone is sure to ring around swarming time. There'll be a hysterical voice on the other end yelling something like, "Your bees have swarmed to a bush in my yard, and nobody dares leave the house." You can tell the caller that swarming bees don't sting. It's almost always true. (If you see a photo of somebody whose face is covered with bees, they're probably swarming bees.) In fact, putting the word out to extension agents, police and fire departments, beekeepers, and anybody else in your area who might receive a "swarm!" call is a good way to build up your bee population on the cheap.

When swarming bees cluster, they all just hang there—solid bees, a little over a foot long, with lots of extras flying around outside. Well, if they swarm onto a branch, they are easy to get, all clustered up like that. You can even do it without your protective gloves on. Just cut off the branch with the bees on it. Hold it over a brood chamber or even an empty cardboard box, anything that will hold all the bees and can be closed up after they're in. Then shake or lightly brush the bees off the branch into the brood chamber. You can do it with a brush or a leafy limb. You can set the hive on a stepladder if it's a higher branch. Bee professionals carry around an extra brood chamber in the pickup just in case they see a swarm they can catch.

At least, that's how it's supposed to work. But bees are very independent. I remember once a swarm was clustered on a branch only a few feet off the ground. The beekeeper set up a hive that was left open on top right underneath the swarm, even put some honey in it. He gently brushed the swarm with a limb into the hive. Then he went away for the night. The next morning all the bees had taken off for who knows where. (If they had been in the hive, he would have put the lid on, blocked the entrance, and taken them home.)

On the other hand, I know a case where the swarming cluster was on a limb 40 feet high. The property owner was pretty insistent about getting rid of them, though, so the beekeeper—mostly to oblige her—left a hive sitting underneath the limb and, by throwing a rope with a weight on the end over the branch, managed to shake a few off and get them scattered on the ground below. Then he went home, fully expecting the problem to have flown far away by the next day. But he got a phone call early in the morning to tell him that—Lo and behold!—the swarm of bees had moved into his hive.

Bee Diseases, Parasites, and Pests
Like any other form of farm livestock, your bees can have these problems. You need to stay in touch with other local beekeepers to know what is currently going around, what the symptoms are, and what the prevention or treatment is. Most states have an "apiary inspector." They're listed in "Who's Who in Apiculture" and they, or a local inspector, can help if you suspect disease. And there is probably an expert in your beekeepers' group. That person can tell you whether your problem is one that legally must be reported and what treatment is advised or legally required.

Basic Bee Hygiene: Don't introduce disease into your hives!
1. Don't buy honey for feed from an unknown source because honey may carry American foulbrood disease.
2. Buy bees and queens only from reputable dealers.
3. Buy used bee equipment only after consulting with your apiary inspector.
4. It helps avoid disease if the bees draw new combs from foundations every 2–4 years for the brood chamber.
5. Learn to identify and treat diseases, parasites, and pests by taking a course or working with an experienced beekeeper, so you'll be able to detect a problem quickly and take appropriate steps.
6. Be alert for those signs of disease each time you open a beehive.

Brood Diseases: "Brood" means the eggs and larvae of the colony. The "brood nest" is made up of all the combs
that have eggs and larvae in them. “Brood diseases” thus are ones that strike the immature bees inside their cells. U.S. beekeepers currently have to be on the lookout for American foulbrood, European foulbrood, and chalkbrood. A healthy brood nest has few unsealed brood cells. The cell caps are slightly convex. Their color is a uniform pale brown. Normal larvae are plump, a lovely mother-of-pearl color, and have no odor.

**Chilled Brood.** This is the most common reason for a dead brood. It happens in early spring, if the population is rapidly expanding and then there is a period of very low temperature. The problem isn’t disease in this case. It’s that there is more brood than there are bees to keep them warm. The bees do their best, but the outer edges of the brood are just too far from the heated area, and they get too cold and die. This is different from an actual disease problem in that you will find dead brood in all stages, both very small and very large. With disease, the dead are all at one particular growth stage.

**Chalkbrood.** A fungus is the problem here. The cell caps will look either light or dark, and some will be punctured. The dead larvae in sealed cells are first white, then grayish black, hard, and chalklike. You should cut away and burn infected combs. Other than that, there is no treatment except that it helps to move the hives to an area with better air circulation, and the disease will then run its course and subside.

**American Foulbrood.** This is the worst of the brood diseases. A bacterium, *Bacillus larvae*, causes larvae to rot in their cells. Foulbrood can be contracted by your bees if they invade an infected colony of wild bees in some nearby old building or tree.

The cell caps look off-colored, sunken instead of convex, and punctured. There are dark scabs at the base of the cells. The larvae look brown, slimy, and dead. If you stick a straw or match into a cell and draw it out, you’ll get only stringy substance. There is a gluey, rotten-egg smell. *American foulbrood must be reported to the state bee inspector*. Treatment must be as mandated by the state.

Last I heard, foulbrood is prevented with a medicine called *Nosema apis* in their intestinal tract. If bees get run down from lack of pollen (their protein source), the nosema can increase to the point of killing their hosts. Affected bees have swollen abdomens and crawl about with trembling wings outside the hive. Nosema disease is most likely to strike in the spring, when pollen supplies are running out. Prevention is easy: Make sure your bees have sufficient pollen, and use a preventive medicine called Fumidil-D.

**Varroaosis.** *Varroa jacobsoni* is an immigrant mite from India, where it coexists with some kinds of bees without seriously damaging them. For European bees, however, it is deadly and will kill untreated colonies in a single season. It is visible to the naked eye. The mites are light brown, oval, and measure 1 × 2 mm. (Males are round and 0.8 mm in diameter.) There is a 6-legged bee louse that is harmless. Varroa has 8 legs. Varroa mites seek drone cells for a critical stage of their life cycle. Kim Flottum wrote: “Treat with the plastic, pesticide-treated strips. If you don’t treat, your colony will die. Count on it!”

**Other Pests**

**Birds.** They do eat bees, but only sick or dead ones—unless they catch a young queen on her mating flight.

**Mice.** These can be a fall and winter problem. The prevention is to narrow the entrances in the fall to just ¼ inch wide.

**Wasps.** These predators kill honeybees and can enter and rob a small or weak colony. A bigger problem is when fall hunger hits and wasps try to get into the hive because, like bees, they too love honey. A strong hive will defend itself successfully. But you can help the bees by blocking off part of the entrance at summer’s end so wasps can enter only one at a time. They’re easier for the bees to kill that way.

**Waxmoths.** These offenders lay eggs on combs, inside the hive. The larvae (caterpillars) that hatch out eat the material in the comb left by the bees, and they burrow through the comb while doing it. They will wreck combs. You can be sure the problem is waxmoth if you see fine gray webs lining paths eaten into the comb. If you have a strong, well-populated colony, the bees cope by murdering each hatching waxmoth larva. Store unused combs where light and air circulation are good to keep these pests to a minimum.

**Bears.** Kim Carlson, one of the editors who worked on this book, asks, “What about bears? My father stopped
beekeeping after bears ruined the hives for the second time. Maybe there’s not much you can do to stop them (short of installing electric wire). This was in the Bitterroot Valley of western Montana, though—probably not much of a problem for most readers.

Harvesting the Honey

Beekeepers usually have 1 big annual extraction. This involves taking the honey-filled supers from the hives and removing the frames. Slice the tops off the wax chambers in the comb of those frames. Then, using an extractor, force the honey from the insides of those storage chambers by centrifugal force—or cut and package the comb directly for comb honey. Extracted honey must then be strained—and bottled and marketed if you plan to sell it. If you’ve already made the acquaintance of a commercial operator, she or he may be willing to extract and strain your honey for you for a reasonable fee. Then either return the emptied comb in its frame back to the bees, or give the bees fresh foundation on the frame on which to build new comb.

When to Harvest?

Harvesting takes place in the fall when the crop is taken off and packed. All those pounds of honey have to be removed from the hives. That means carried away in the supers in which they’ve been stored by the industrious bees. Professionals wait to harvest until the major nectar flow is over. That’s when the flowers are mostly gone—about August. You can begin as early as late June or as late as mid-September. But too late a harvest risks leaving the bees with too little honey since they have less time to replenish their stores.

How Much Honey to Take?

An average-sized family can use about 5 gal. of honey a year. Our large one uses about 10. To harvest that amount of honey, a family needs 2 or 3 hives. But don’t take that much (or any at all) unless you can leave the bees with enough honey—60–100 lb. per colony, depending on how long and cold your winters are—to survive until the next flowering season. Bees can gather food only when there are flowers. The rest of the time they must live on their stored food.

Comb Honey: You can eat your harvest right out of the frame, in the comb, just as the bees made it. The wax is fine to eat—not really food for humans, but not harmful to eat. You can spread comb honey like any thick spread. Eating comb honey avoids the expense and struggle of the extraction process. All you need to eat your harvest comb honey is a sharp knife to cut blocks of it out of the frame. If you want to learn more about producing this gourmet market item, read Richard Taylor’s The New Comb Honey Book (1982). To preserve honey in the comb, save your nicest combs with the caps on, stand them edgewise in a crock or metal can, and cover with extracted honey. For commercial sale of comb honey, beekeepers used to put little wooden square boxes into the hive instead of regular frames. The boxes for comb honey were made out of basswood because it bent easily. But that sort of comb honey is seldom sold any more.

Uncapping the Comb: The beekeeper’s equipment probably consists of an electric knife to uncap one side of the frames, or else a hollow knife with steam run through it so the knife is hot. Either one slices the caps off the honey cells very nicely and easily. You can mail-order an electric knife from your beekeepers’ supplier that is perfect for that uncaping. Keep the frames in a warm room before extracting so the honey will flow out easier when the centrifugal force is applied.

Processing Caps. I watched an expert beekeeper do this. He had a special vat for the slicings to fall into. They are valuable as beeswax as well as for the bit of honey still clinging. Heated coils help separate the slicings in the vat from the honey sticking to it. A little stream of melted wax comes out one side and the honey comes out the other. That is the only wax a professional beekeeper harvests—just the caps. He keeps the rest for the bees to use again.

Machine Extracting: Then the beekeeper put the entire ununcapped frame into the extractor. The commercial extractor is a big round drum that will hold 30–140 frames at once. (I’ve also seen a small manual style that holds just 3.) The ununcapped frames are set into holders inside the extractor, their ununcapped side facing the outside of the extractor. Then the extractor is made to whirl them around very fast, which causes the honey to flow out by centrifugal force (the force flings it against the wall of the drum). It flows down the wall and is collected at the bottom, being piped directly to a holding tank. Smaller versions of an extractor can be bought through the Root Catalog, among others, but you don’t have to have one.

Hand Extracting: I have heard of squeezing honey out from the wax by hand, but that is an awful waste of drawn comb. A better system is to cut off the tops of the honey cells, and hang the frames up over a heat source like a wood stove. The honey will melt and drip down. Have something under there to catch it, of course. You have to do one side of the frame, and then the other. Or make a Rube Goldberg contraption with an electric drill top and a “barrel” bottom that will grip and spin your ununcapped frame.

If you need the wax for candle-making anyway, the easiest method of all to get honey without an extractor is to melt the whole thing down together. Just make sure you use frames that are clean and don’t have baby bees in them—they’ll mess up the taste of the honey. You need frames that are solid honey. Leave the frames with some baby bees in them to feed the bees in winter. Cut the honey, comb and all, into chunks in a great big stainless steel fry pan. Melt it. Skim the whitish wax off the top and strain it into a
separate pan. Strain the rest of the honey through a cloth set over a deep pan. Pour that strained honey into quart jars. You can let the honey with all the wax in it cool until the wax rises to the top. Then you can easily take it off. The honey that was with the wax can be reheated and poured into another jar. It's all that simple.

**NOTE:** Don't heat honey in an iron kettle. That will cause it to darken.

**Wax in the Honey:** If the honey looks messy, heat and strain it. It wouldn't hurt you a bit to eat wax, but there are better things to do with it. Melt the honey-wax mixture in a double boiler over gentle heat. Take off the scum with a skimmer as it appears. You can sell the wax, make new foundation with it, or make candles. Pour your now wax-free honey into widemouthed jars and seal.

**Cleaning Beeswax for Candles:** Beekeepers sell unfiltered wax for $1–2/lb. You can get it by the 10-lb. chunk. Or prepare your own. To make candles out of beeswax that has come fresh from the hives, a good way to do the first step of cleaning is to place it in a box on top of a beehive. The bees will promptly come and within a day they'll have every last speck of honey cleaned off it and carried back into the hive. But don't leave it there after the bees have it cleaned off because then wild animals will carry it off. Take it back in the house and finish cleaning it by melting and straining the wax. The very best filter for beeswax is sweatshirt material. Cheesecloth is much too porous. In factories they force it through canvas under great pressure, but sweatshirt material is better. Wrap the filter around the beeswax; as the melted wax drips down, the impurities are left behind. Beeswax melts at 130°F. A very gentle heating can be accomplished in a solar wax melter.

Here's another system to clean and lighten your wax if it's dark and dirty looking: Add a little cider vinegar to the wax and some water and hold it at 135–140°F for 2 or 3 days, if possible. The dirt settles to the bottom, and the honey collects in a layer just below the wax, which floats on top.

**Storing Honey**

Honey keeps easily—better than just about anything else. It doesn't need to be frozen, canned, or even refrigerated. It keeps just fine in glass, plastic, pottery, or metal, inside or outside. Don't refrigerate honey because that hastens the granulation process, and, unlike many other foods, it doesn't need to be kept cool. But store where it won't get warmer than 75°F since above that temperature it may lose flavor and color (the higher above 75°F, the faster the change).

A wide-topped container that you can scoop out of is handier than a 5-gal. can with a 2-inch opening. If the contents of a narrow-necked container crystallize, you have to melt the whole supply every time you need a quart—and each time you heat it up you may lose nutrition and flavor. Honey that isn't frozen will crystallize, eventually. And a 5-gal. can of honey weighs 60 lb. and thus is too heavy to accomplish much with easily. Best of all, pack your honey in widemouthed 1-gal. jars. Then keep a quart container of honey in your kitchen for current use. And keep your kitchen honey in a fairly warm place. Chilly, stiff honey won't mix with other ingredients very easily.

**Crystallized (“Granulated”) Honey:** Any liquid honey may crystallize into a stiff, whitish texture if stored in a cool place. Sometimes this happens after only a week or so, sometimes after several months. This process is called “granulating” and is normal. It doesn't harm your honey a bit. It doesn't change it at all, once you've remelted it. Or you can use crystallized honey as is. It won't affect your recipe, except in that you've added a bit less liquid.

**Re-Liquefying Crystallized Honey.** When my honey in the can gets sugary on top, I just put the can on the back of the wood stove or on very low heat on the electric stove, and the sugars will go back into solution as fast as it warms; 130°F (water no hotter than you can bear your hand in) is a perfect temperature for the job. You can warm a quart jar of honey in a double boiler. Honey in a glass container can be liquefied in a microwave oven. (Remove the cover first! Then cook on high 30 seconds or until clear.) No matter what your method is, be careful not to overheat. Don't boil the honey because that ruins the delicate flavor. Just keep it at about 130°F until it liquefies—it may take hours, or days, depending on how much honey you're working with.

Storing it in a warmer place will help avoid a repeat. Unlike most food storage, storing honey at a warm temperature, in a closed bottle, does not result in any loss of flavor.

**Other Bee Products:** Pollen, propolis, beeswax, and royal jelly can also be sold. Propolis is the resinous substance bees use to fill holes and gaps in the hive. It takes a lot of work to produce royal jelly, and there isn't much market for it. Beeswax sells well, but you need many hives to produce much.

**Using Honey**

**NOTE:** Don't feed your baby honey. Botulism spores can be in it. These don't harm adults when directly eaten, but in the intestines of infants under 1 year of age—especially under 6 months of age—they can grow. This was discovered in 1976 and is now thought to account for at least some cases of Sudden Infant Death Syndrome. Keep these small babies out of soil (where botulism spores are) in general.

**Honey at the Table:** Get 2 small syrup pitchers. Fill one with honey and one with molasses or sorghum. If you grow it, or can afford it, you could keep a third with real maple syrup in it. Keep the honey pitcher in a warm spot in your kitchen—over the pilot light or on the warming shelf of your wood stove. Serve both pitchers whenever needed at your meals. Honey complements the taste of any herb tea just perfectly, helping to bring out the flavor. Basically, you can use honey anywhere you can use sugar: to sweeten any beverage (tea, coffee, warm milk), stirred into plain yogurt, dribbled onto cold or warm cereal, mixed with margarine or butter, or blended with any nut butter to make a spread.

**Cooking with Honey:** Honey has been around longer than refined sugar. Honey is composed of simple sugars, mainly fructose and glucose. Plain white sugar adds sweetness to a recipe, but honey adds flavor as well as sweetness. The sweet taste of honey tends to be more concentrated than that of sugar, so you can substitute 1⁄4–1⁄4 c. honey for any 1 c. sugar and end up with it equally sweet-tasting. You can substitute honey for sugar in any recipe, but because honey is a liquid you then decrease the liquid in the recipe by 2–3 T. per 1⁄4 c. honey, or by 1⁄4 c. per 1 c. honey. Honey is easiest to measure if your measuring container has first held the oil or other fat for the recipe, or if you first coat the spoon or cup with oil (or with nonstick pan-coating spray). Then the honey won't stick in the
measuring container and you'll be able to get it all back out easily. Combine honey with other liquids in the recipe.

**Preserving with Honey**

**Freezing Fruit with Honey.** Don't make a heavy syrup. Use 1 c. honey to 2 c. water. That will give you what the recipes call a "medium" syrup. For a "thin" or "light" syrup, use 1 c. honey with 3 c. water. Then allow ½-1 c. syrup per 1-qt. freezer container. Measure your syrup into the container. Slice fruit directly into it and freeze. You won't need any ascorbic acid when you freeze fruit in honey syrup. The syrup itself will prevent the fruit from changing color. Add a crumpled piece of freezer paper to keep the fruit forced down under the syrup. Peaches and strawberries are especially good this way.

**Honey Fruit Jam** To make Doris's gooseberry jam combine 3 c. green gooseberries and 2 c. clover honey. Cook slowly until mixture jellies on a cold dish. Put in jars and seal. This is simple and very good, and you can apply the same principle to other fruits.

**Uncooked Berry-Honey Jam** Mash fresh berries (raspberries or strawberries are very good in this). Put the mashed berries in a blender with a package of pectin and blend. Taste. Now add as much honey as you think it needs to be sweet enough, and blend again. You can make only a little bit of this at a time because blenders don't hold much. Store it in the refrigerator.

**Lemon-Honey Jelly** From Nanci Falley, Lockhart, TX: Combine ⅔ c. lemon juice and 2⅔ c. honey. Bring to a full rolling boil. Add ⅓ c. liquid fruit pectin, stir vigorously, and boil about 2 minutes. Pour into hot sterilized jars and seal.

**Canning with Honey.** Honey can be used as the sweetening agent in canning, jelly-making, and other preserving. Since different types of honey vary in darkness, so do honey syrups, but they're invariably at least somewhat darker than a sugar syrup. This darker syrup will tend to darken light-colored fruits like pears and peaches. But the flavor will be delicious, so don't worry about the color. Honey syrups, compared to sugar syrups, have more of a tendency to foam when heated; use a larger kettle and watch it carefully to avoid boil-overs.

**Honey Syrup for Canning** When canning apples, tart cherries, plums, and strawberries, try 2 c. of honey per 3½ c. water. For syrup over blueberries, black cherries, peaches, pineapples, and raspberries, try 1 c. honey per 2–3 c. water. These proportions can be experimented with and varied according to your personal taste and need. It is entirely up to you how much or little honey you use. You can use plain water or pure honey or anything in between. The canning process and times are the same no matter what the type and amount of sweetener.

Prepared your fruit for canning. Place it in a pan, cover with the syrup, and heat thoroughly. Put into prepared jars, filling to within ½ inch of the top. Put on lids, tighten them, and process in a boiling water bath the appropriate amount of time for your size of jar and type of fruit.

**Honey-Fruit Jelly** Combine 2 c. high- or medium-pectin fruit juice, ½ c. mild-flavored honey, and 2 t. lemon juice. Bring to a boil and stir in at once 2 T. powdered pectin. Let boil 10 minutes, and pour into your jelly glasses. For low-pectin fruit juices, use 4 t. lemon juice and 3 T. powdered pectin. If you want to use homemade pectin, substitute 2 c. homemade pectin for both the lemon juice and powdered pectin.

**Baking with Honey.** Marilyn Gordon and her husband raise and sell honey at Boone, CO. She wrote to me: "To substitute honey for sugar in a baking recipe use ¾ c. honey for 1 c. sugar and reduce liquid in the recipe by ¼ c.—like in cakes. If liquid isn't called for in your recipe, add 4 T. additional flour for each ¼ c. honey used in cookies. Bake at a temperature 25 degrees lower than called for, as baked goods with honey will brown faster. Cakes, cookies, and breads will be moist and stay fresher longer because of honey's moistness."

Honey is acidic. If there is as much as 1 c. of honey in the recipe, you can add ½ t. baking soda (per 1 c. honey) and get a leavening action as well as neutralize the acidic quality.

These next few recipes were presented to me by Shawna Marie Thurman, 1988 Montana Honey Queen, courtesy of Western Bee Supplies.

**Beehives** In a mixing bowl combine ¼ c. honey, 1 beaten egg, and 1 t. vanilla. Beat until well blended. Stir together 2 c. shredded coconut, 1 c. chopped walnuts, and 1 c. chopped dates that have been coated with 2 T. of flour. Now add them to the honey mixture. Drop your beehives by tablespoonful onto a greased cookie sheet. Bake at 325°F for 12 minutes or until done.

**Honey-Applesauce Cookies** Cream together 1½ c. honey and 1 c. shortening. Add 2 beaten eggs and beat mixture until smooth. Add 2 t. baking soda to 2 c. applesauce. Sift in 2 t. cinnamon, 1 t. nutmeg, 1 t. salt, and 3½ c. flour. Stir in 2 c. quick-cooking oats (or rolled wheat), 2 c. raisins, and 1 c. walnuts. Drop on cookie sheet with a spoon. Bake at 325°F for 10 minutes.

**Honey-Fudge Brownies** In a saucepan over low heat, melt together ½ c. butter, 2 squares unsweetened chocolate, ½ t. salt, and 1 t. vanilla. Mix well. Remove from heat. Blend in 1 c. honey, ½ c. unsifted flour, and 1 t. baking powder. Add 2 well-beaten eggs. Beat the mixture well. Pour into a thoroughly greased 9-inch-square pan. Bake at 325°F for 35 minutes (or until done in center). Cool on wire rack 15 minutes before marking in 16 squares.

**Other Honey Recipes**

**Caramel Corn** Combine ½ c. honey with ¼ c. brown sugar and 2 T. margarine. Heat until sugar is melted and bubbling around edges. Pour over large bowl full of popped, salted popcorn, and mix well.

**Stretched Honey** You can stretch your honey by mixing 1 c. honey with ½ c. sugar and ¼ c. water. Heat and mix together. Serve warm. Stretch it even further, if need be, by combining ½ c. water and 1 c. brown sugar per 1 c. honey.

**Honey Syrup** To use straight honey for syrup, warm in a pan of hot water before serving so it will pour easily, or else mix with about one-fifth water. A honey-buttermilk syrup for immediate use can be made by melting about 3 T. butter per ½ c. honey. Serve while hot, and stir when necessary to redistribute butter, which will tend to float. Or swirl before each pouring to mix.

**Honey Lemonade** Stir ½ c. honey into a quart of very hot water. Add fresh lemon juice (from about 4 lemons)
or some form of lemon juice concentrate, to taste. Serve warm for a wonderful winter treat, or chill to serve in the hot summertime.

**Honey-Cream Sauce** Whip ½ c. cream, then beat in ½ c. honey and 1 t. lemon juice.

**Orange Sauce** Combine ½ c. butter, ½ c. honey, 1 T. orange juice, and 1 t. grated orange rind.

**Honey Tea** A bee man taught me this one. Put water on to boil. When it’s boiling, add 3 t. honey per 4 c. water and boil a few minutes more until thoroughly in solution. Add tea leaves to make tea. Steam, strain, and serve. For iced honey tea, make as above, then chill.

**Honey Dressing for Fruit Salad** Combine half honey and half lemon juice. Add a bit of yogurt and some cinnamon. Store, covered, in the refrigerator.

**Cracker Jacks Made with Honey** From Marilyn: “Blend ½ c. melted butter with ½ c. honey. Heat until well blended. Pour over a mixture of 3 qt. popped corn and 1 c. chopped nuts. Mix well. Spread over cookie sheet in thin layer. Bake in preheated 350°F oven for 10 to 15 minutes until crisp. Be careful, mixture is very hot.”

**Broiled Honey Topping** Also from Marilyn: “Mix ¼ c. soft margarine or butter with ½ c. honey, ½ c. shredded coconut and ¼ c. chopped walnuts. Spread over top of hot 9-inch-square cake. Broil until topping is bubbly. Tastes best served warm. Or heat ingredients in saucepan, thin with several spoonfuls of milk, and serve over ice cream or pudding.”

**Rabbit**

I’m used to living way out in the country, and that is where I went through my rabbit period and quickly raised 30 or so rabbits with no neighbor problems (it was the goats we had complaints about). But that was near a community of 300, and we had 3 acres. In town, even for just 1 rabbit, learn the zoning rules first. Usually, there’s no problem keeping a few rabbits, but sometimes the law specifies how many or where the hutches must go. Of course, some folks keep illegal rabbits, even enough for meat or marketing breeding stock. Being small and silent—unique and wonderful in that way among livestock—rabbits are the easiest of all to hide.

I used to think rabbits were rodents like rats and mice, but now I know they belong to a different group of mammals. They are “lagomorphs.” Whatever you call them, rabbits are lovable, docile, quiet, small animals. They make good pets or can be raised for meat. They are so gentle even a child can manage them, so unobtrusive that even a covert back yard farmer can raise them. So you can raise rabbits almost anywhere: in town or country, in backyard or garage, in a house—even in an apartment!

Rabbits, of course, are also famous for their reproductive abilities. Lane Morgan says, “My elder daughter wants a pair of bunnies so she can raise babies. I told her the only way we were raising lots of baby bunnies was if we were going to butcher them, so she is brooding over this hard bargain.” Yes, that’s how it has to be. If you’re going to make rabbit part of your meat production—or if you’re going to keep 1 or more for pets—here’s what you need to know.

### Getting Started

**Magazines:** *Domestic Rabbits* comes out 6 times a year from the American Rabbit Breeders Association, c/o Glen Carr, PO Box 426, Bloomington, IL 61702; arba@arbal.com; www.arba.net. The magazine, *Standard of Perfection*, and breed guidelines are available to members—$15/yr for adults, $8 youth. Send $2 for their beginner’s booklet, $5 for their rabbit cookbook, or $1 for a bumper sticker “Get into the Rabbit Habit.” It’s a good place to find local rabbit clubs, rabbit products, and basic breeder stock.

**Rabbitry Suppliers**

**Bass Equipment** offers the “world’s most complete line of rabbit and small stock equipment”: PO Box 352, Monett, MO 65708; 417-235-7557; fax 417-235-4312; www.Bassequipment.com.

**Care Zap’s It** sells an Odor Digester and rabbit care products; send long SASE for brochure: 11727 Leader, Houston, TX 77072.

### Vocabulary

**Buck:** male

**Bunny:** a baby rabbit, also called a “kit”

**Crib:** to chew on a wooden cage

**Doe:** female

**Droppings:** rabbit feces

**Hutch:** a rabbit cage

**Kindle:** to give birth

**Junior:** young rabbit of either sex

**Rabbitry:** where your rabbits live

**Run:** group housing of a “natural” sort

**Senior:** an adult
BUYING STARTER STOCK

Finding Rabbit Breeders. You could probably arrange to buy your first rabbits from someone exhibiting at the fair, or ask advice of the fair superintendent or extension agent. They may know of rabbitries close enough to visit. In addition, good places to inquire are the local newspaper's stock-for-sale section, especially if you live in a rural area, and the local feed stores. Look over the feed store bulletin board and ask the clerk for advice. Because most rabbit owners buy feed and/or vet supplies, feed store clerks know who has what—and also have an idea how well cared for the animals are.

Get Good Stock. No matter whether you're buying papered or mixed-breed stock, get healthy animals—the best ones you can afford. You'll have a better idea which ones are best cared for and the best stock after visiting several rabbitries. Be cautious, even suspicious. A good rabbitry is clean. The animals look alert and happy—not listless and droopy. Ask what the rabbits are being fed and about other aspects of their care. A good match would be a rabbitry where the animals are fed and managed very much like you intend to do.

Try to catch any problem before you put your money down. It's normal for the rabbit owner to want to unload a cull rather than the best rabbit. Why a cull and how bad a problem are your questions to answer. And all are not necessarily problems; a discard from a classy operation could be a great start-up animal for you. On the other hand, that cull might have a truly unfortunate condition such as a disease or bad genes that could doom your operation.

What to Start With. The minimal option is a single rabbit for a pet or a single bred female to start your rabbitry. You can go from that one pregnant doe to having enough rabbit for dinner every day and some to sell within 6 months. Rabbits are famous reproducers. But most people choose to start with more than 1, such as 2 bred does and the mature buck that bred them. These rabbits know what to do. Or choose a mature buck and pregnant doe, plus a junior buck and doe. This protects in case of failure by the older rabbits who may have been sold because they were close to stopping reproduction. Or get just a buck and a pair of does, all fairly young. Your trio will probably be plenty to start your own rabbitry.

Changing a Rabbit's Diet. Most livestock arriving new at your home will make the transition better if they don't have a sudden change in diet. Before you take them home, ask the previous owner what the rabbits have been fed, what feeding schedule, and how much of it. Ask the previous owner to sell you enough feed to help them make an easy transition, gradually switching from old to new if you will be feeding them differently.

You change a rabbit's diet by adding a little larger part of new feed and a proportionately smaller part of the old every day until the changeover is fully accomplished. Check their feed container to make sure they're eating the new rations okay. They may refuse a new food. Rabbits can be picky and opinionated. And going from an all-pellet diet to a home-grown one, for example, is a big transition; give it several weeks.

Quarantine. Any time you bring new animals onto your farm, it's a good idea to quarantine them away from other animals of their kind for 2 weeks or so. You may never run into a problem of a new animal getting sick. But if you do, you'll be glad you didn't let the other animals get it.

Rabbit Breeds

A good way to start getting acquainted with your many choices in rabbit breeds is by attending the rabbit exhibit at your county fair. It will be with poultry and other small stock. For a pet, pick any breed that catches your eye. Basically, a rabbit is a rabbit, but for anything beyond a few pets, you'll want to choose your breed carefully.

You have 5 things to consider: (1) Commercial meat breed with good food-to-flesh conversion ability and fast growth—or a noncommercial "fancy" breed? (2) Color? The Harlequin is a "calico." The chinchilla has a "ticked" fur. Many other rabbits come in 1 or more solid colors, such as the white, red, or black New Zealands. (3) Pelt type—long or short fur? Angoras have long, fluffy hair. Rex have a short, velvety fur. And you can find almost anything in between. (4) Size—dwarf, medium, or giant? (5) What appeals to you personally?

OF RABBITS AND PEDIGREES: "Mixed breed stock" may look like some breed or other, may be in fact purebred, but without the paper proof they aren't "pedigreed" or "registered." There are 45 recognized rabbit breeds. One listing of rabbit breeds is the Official Guide Book of the American Rabbit Breeders Association, free if you join the ARBA. The registering of rabbits has some unusual rules. It isn't good enough just to have the pedigreed parents and grandparents, and to be a member of ARBA. In order to be registered, the animal must also be an adult. Babies or young rabbits cannot be registered. And rabbits can't be registered through the mail. They have to have an inspection by an ARBA representative, a "registrar." The registrar checks your rabbit for physical defects and to see if it measures up to breed standards.

MEAT BREEDS: Rabbits produce more meat for less feed than any other livestock. And rabbit is the leanest land-grown meat. There are only 2 solidly commercial rabbit breeds, the New Zealand White and the California. Those have the best meat-to-bone ratio, good pelts, and have been selected for fast, efficient growth. New Zealand Whites and Californians both make white pelts (Californians have black spots on their ears, feet, nose, and tail, but they don't show up on the pelt proper). Commercial breeds are white because fur-market buyers prefer white skins—they take a dye. Other meat breeds are the Champagne d'Argent, Chinchillas, New Zealand Reds and Blacks, and Satins. Commercial meat rabbits are available from Aspen Hill Farms, Box 753 Anderson Rd., Boyn City, MI 49712; 231-582-6790.

RABBIT SIZES

Dwarf. "Dwarf" rabbits usually have fairly short ears and a stocky build, and grow to weigh only 3 or 4 lb. You could raise a dwarf breed and get meat from them, but there isn't much meat on one, and their feed-to-flesh conversion ratio isn't as good as the standard meat breeds. There are some breeds that have always been small. Others are small versions of some medium-sized breeds, such as the dwarf lops. Popular dwarf breeds are Dutch, Himalayan, Netherland Dwarf, and Polish.

Moderate-Sized. The 2 commercial breeds described above, as well as Angoras and many of the so-called "fancy" breeds, all weigh from 6 lb. to 10 lb. as adults.
That's average "moderate" rabbit weight, with the dwarf breeds coming in lighter and the giants heavier. Other medium-sized breeds are the Angoras, Champagne (and Creme) d'Argent, Chinchillas, English Spot, Harlequin, the various lops (they have long, flopped-down ears), Rex, and Satins.

**Giant.** I used to believe that the best kinds for meat were any of the giant varieties: Checkered Giant, Flemish Giant (up to 14 lb.), and Giant Chinchillas (the chinchilla rabbit coat plus giant size). But I've since learned that others make far better use of feed to make meat. Giants are relatively big when they're born and, like any rabbit, grow up fast. With luck, a breed like Flemish Giants might butcher out to a 3-lb. carcass at 10 weeks. If you wait and keep feeding, shortly later they'll make a 5-lb. carcass. They are impressive looking. You can get Flemish Giants in various colors. Checkered Giants are a little smaller with a distinctive black-and-white spotted coat.

**SHOW BREEDS:** How people tend to run after anything they think is new or will make them quick and easy money! In the rabbit field, the Belgian "hare" (actually a true rabbit) was a fad that made early investors profit but caused late-comers to the buying spree heavy losses. They are long and lanky in build, not good meat animals. The Belgian hare is a perfect example of a "fancy" breed show rabbit. These breeds, of course, are fine pets and enable their owners to play the win-a-ribbon game. That's good clean fun but not what this book is about.

**ANGORAS, THE WOOL BREED:** "Angora wool" comes from Angora rabbits. You pull it off them just as they pull it off themselves to make wonderful nests to have babies in. It's fine for spinning or stuffing, but it takes a lot of rabbits to accumulate enough fiber to work with. They are cute, cuddly things but must be plucked or brushed out to get wool for spinning. You can't shear them like a sheep. Plucking is work. Whether you have a use or a market for their wool or not, you still have to keep them brushed for the sake of their health and cleanliness.

Angoras are not a good choice if you live in a hot climate. They suffer in heat. The cage of an angora is harder to keep clean because of the tendency of their sheddings to build up on the cage floor, blocking feces from falling through the wire and trapping urine in the cage. So you have to watch angoras carefully for any signs of hutch burn or skin diseases. It's their cells that begin these skin problems; it can be caused by hutch burn. Angoras are not good choices if you have other breeds coming in lighter and the giants heavier. Other medium-sized breeds are the Angoras, Champagne (and Creme) d'Argent, Chinchillas, English Spot, Harlequin, the various lops (they have long, flopped-down ears), Rex, and Satins.

**Giant.** I used to believe that the best kinds for meat were any of the giant varieties: Checkered Giant, Flemish Giant (up to 14 lb.), and Giant Chinchillas (the chinchilla rabbit coat plus giant size). But I've since learned that others make far better use of feed to make meat. Giants are relatively big when they're born and, like any rabbit, grow up fast. With luck, a breed like Flemish Giants might butcher out to a 3-lb. carcass at 10 weeks. If you wait and keep feeding, shortly later they'll make a 5-lb. carcass. They are impressive looking. You can get Flemish Giants in various colors. Checkered Giants are a little smaller with a distinctive black-and-white spotted coat.

**SHOW BREEDS:** How people tend to run after anything they think is new or will make them quick and easy money! In the rabbit field, the Belgian "hare" (actually a true rabbit) was a fad that made early investors profit but caused late-comers to the buying spree heavy losses. They are long and lanky in build, not good meat animals. The Belgian hare is a perfect example of a "fancy" breed show rabbit. These breeds, of course, are fine pets and enable their owners to play the win-a-ribbon game. That's good clean fun but not what this book is about.

**ANGORAS, THE WOOL BREED:** "Angora wool" comes from Angora rabbits. You pull it off them just as they pull it off themselves to make wonderful nests to have babies in. It's fine for spinning or stuffing, but it takes a lot of rabbits to accumulate enough fiber to work with. They are cute, cuddly things but must be plucked or brushed out to get wool for spinning. You can't shear them like a sheep. Plucking is work. Whether you have a use or a market for their wool or not, you still have to keep them brushed for the sake of their health and cleanliness.

Angoras are not a good choice if you live in a hot climate. They suffer in heat. The cage of an angora is harder to keep clean because of the tendency of their sheddings to build up on the cage floor, blocking feces from falling through the wire and trapping urine in the cage. So you have to watch angoras carefully for any signs of hutch burn or skin diseases. They're more likely to get these than regular rabbits, and beginning skin problems are harder to detect under all that fur. Water your angoras from a sipper bottle because they soak their neck fur when drinking from a more open container. When butchering them, you must take care to keep their long hair off the meat.

ABUnDance Acres Fiber Farm offers both French and Giant Angoras, plus black-and-blue Giants: 9713 Crystal Falls Dr., Hagerstown, MD 21740; 301-791-1110; OsBunny@aol.com.

**Housing**

**NOTE:** Plan rabbit housing to protect against heat and predators.

**OF RABBITS AND HEAT:** An important thing to know about rabbits is that they can't stand heat. Too much will kill them. Rabbits like some sunlight as long as they don't get too hot. If you get into terribly hot "dog days" in July or August, take your hose and soak the roof of the rabbit hutch a couple times each afternoon. During the hottest weather, make sure your rabbits always have plenty of water, but feed them only a little during the day, mostly at night. It will help if you set the hutch under a big tree or where a large building will shade it from afternoon sunlight. If you haven't taken these precautions against overheating, you can lose a batch of very nice rabbits real fast. When they die of heat, they look fine in the morning and in the evening when you look again, they are dead. I've had that happen to me.

**PREDATOR PROTECTION:** The biggest danger to your rabbits, however, is not temperature or disease, but predators. Rabbits have long done service fairly low on the food chain, and the predators around you instinctively know that. You have to consciously and carefully and diligently protect your rabbits from carnivores, whether you live in town or country. Predator protection starts with the good fence around the place where your hutches are, whether yard, garage, or outbuilding.

The common predators are dogs and cats, both wild and tame, as well as big birds of prey, coyotes, and wildcats. Wandering dogs may actually rip at cages trying to get a rabbit, or bite the feet of young bunnies if they step through the rabbit wire flooring the cage. Dogs have even managed to bite through wire net and kill a rabbit. Even if they can't get at a rabbit in a well-built cage, the scare from the dog trying to cause a doe to kill her babies. Children have to be viewed as possible predators, too. Like the dog, they may upset a new mother and cause cannibalism, or leave a cage door open, or feed a poisonous plant.

**HOUSE RABBITS:** Rabbits can be litter-box trained! Rabbits have dwelt in houses, apartments, condos—even (secretly, of course) in college dorms. Some house rabbits are kept caged. Others run free, at least in 1 room—when not confined to a paper-lined cage/house on the deck or some such. The biggest problem with house rabbits is that you have to be careful about taking them outdoors, since they're accustomed to house temperature and comfort.
They are more likely to get sick if moved outdoors than an outdoor-raised rabbit would be. To housebreak, just keep papers down where you want the rabbit to potty. The first time, it helps to demonstrate by putting some rabbit feces and urine on the paper. Your rabbit has an instinct to use the same place over and over as its toilet.

**Rabbit Runs:** I got a letter from a lady who has about 80 rabbits living in her garage. The garage has a dirt floor. That living arrangement is called a “rabbit run.” Most rabbit runs include an outside, fenced area. Advantages of a rabbit run are low stress, potentially less feeding, better meat because of exercise, better pelts from colder air, and healthier rabbits in that fresh-air environment. The very natural setting for the rabbits reduces their stress. They need less feed because they will eat some grass or whatever good forage is growing in their area. The disadvantages are that they’re harder to catch, less likely to act like pets, and harder to keep breeding records on.

Rabbits are communal by nature and not inclined to fight much. People have had up to 100 of them in this arrangement without losing more than 2 or 3 to fights. The letter-writer said most of her does run loose on the lawn that small space it will be easy to catch rabbits. Flooring for Rabbit Runs. The rabbits will be happy in any building if you don’t mind the floor being covered with manure. You can keep them in a floor run or in wood hutches, or metal cages in a garage, shed, or any outbuilding. A very good floor management system is to place plenty of organic bedding such as straw under the cages to collect the urine for your garden. Once in a while you’ll have to shovel out that soiled bedding. If the floor is cement, you can then wash it after shoveling out. Rabbit hutches on wood floors eventually rot the floor. You can delay that by laying heavy plastic over the floor. Extend it so the plastic goes up part way on the side walls. But better flooring for rabbits in or out of cages is dry dirt. Or best of all, put them on pasture!

**Portable Pasture Runs.** This may well be the ideal way to manage rabbits in any season when you have green things growing. The cage looks like a long A-frame. It has a solid wooden shelter at one end to protect from bad weather. The remaining sides are wire and let in sunshine, which, incidentally, rabbits need to be healthy. There is no floor to the cage. You place it over the green growing stuff, the day’s grazing for your bunnies. This way you don’t need to feed them as much other food.

**Rabbits in Cages:** Cages can be made of wood or wire. They can be single or built as units in a row, 2 or any number more. Multiple wooden cages are easy to build, but you’d better make them where they’re going to stay because they’re very difficult to move. No matter whether you’re building with wood or wire, space needs and design features for rabbits are the same.

**Cage Size.** First decide how many rabbits you’re going to keep and how large a breed they will be. (The housing, of course, should be prepared before the rabbits arrive.) In general, plan 1 square foot of floor space per lb. of rabbit that will be living there. The minimum though, even for a bachelor buck or pet is $2 \times \frac{3}{4}$ feet. Then figure out how your rabbits will be divided up into separate cages. A buck lives by himself and doesn’t need as much room as a breeding doe, who will need space for a nesting box and her growing family. Your 9-lb. bunny would be content in a 3-foot square cage, but could you reach her? Don’t make any cage so big that you can’t reach every corner of it from the doorway with your arm. Otherwise you may be groping in vain for a reluctant bunny that has placed herself just out of your reach. Build either a narrow cage with a wide door, or a big roomy cage with a lid that lifts off when you need to get in there.

**Outdoor Hutch:** Another housing option is a hutch out in the open. These cages are built solidly enough that they can stand alone outdoors and still keep the occupants warm enough in winter. If you have wood and a little inclination toward carpentering, a wooden hutch is easy to build. Wire hutches can actually be put together fairly easily too, once you get the hang of it. You can make a small hutch for a single occupant or construct multiple units. A good hutch style is a large, airy one set up on legs or posts so air can circulate easily under and around the hutch through its chicken-wire sides and bottom. But if your
climate is cold, or during cold times of the year, you may want to protect the rabbits from bottom drafts by adding a wood or cardboard skirt surrounding the legs of the hutch. You could skirt only the sides and front or back, thus leaving one side open for cleaning manure out from under. In the coldest weather you could put a temporary skirt on that last side too.

**Hutch Roofing.** The hutch top can be made of wood covered with metal or asphalt roll roofing or even sturdy plastic. Include overhanging eaves that extend far enough over the sides of the hutch to shelter your rabbits from excessive sun and all rain, including what might fall on the outside portion of feeders if you have the style that extends to the outside of the cage.

**Hutch Sides.** This depends on your climate or season. You can have wire all around, or a solid (wooden) back and wire at the sides and front, or solid 3 sides round and wire only at the front. The wire sides are usually made of 1-inch poultry netting ("chicken wire"). Chicken wire is not the sturdiest of wires. You'll have to check it regularly for tears (a determined rabbit can make a hole in it with its teeth). Also, keep in mind that wire ages. The older it gets, the weaker it gets.

**Hutch Flooring.** Wooden floors will be chewed on by rabbits, soak up urine, smell, and are considered not as healthy as wire. On the other hand, rabbits can be happy on them so long as they're in good repair and you provide plenty of clean bedding to go over the wood such as sawdust, straw, hay—and clean as needed. The floor will be hardware cloth or "rabbit wire" (⅛-inch mesh). Be careful when putting in the rabbit wire because it has a "right" and a "wrong" side. The wrong side has a galvanized coating that can develop sharp points that hurt even furry feet. Another problem with rabbit wire is that the holes are so small that droppings mixed with hair may not fall through. You could use wire with bigger holes to floor the cage. That decision depends in part on what breed you're raising—how big their feet are! Bigger feet need bottom wire with smaller holes.

Most hutches have a wire floor so the droppings can just drop right on through. The wire keeps the cage clean of feces, but sometimes it's hard on rabbit feet (see "Vetting"). Galvanized wire, 1 x ½-inch, is usual for medium or dwarf breeds. For larger rabbits, use 1 x 1-inch, 14-gauge. In summer, clean out the hutch if the manure starts building up in it instead of falling through. In winter, the manure in an outdoor hutch may help keep the rabbit warm.

**ALL-WIRE CAGES:** Compared to wooden hutches, these are more exposed to the weather and so must be enclosed in a protective outer building. Other than that drawback, they last well and are easy to clean and to move about. You can buy them ready-made in various sizes, or make your own. Commercial rabbit feeders and water bottles attach easily to the wire.

**An Enclosing Shelter for Wire Cages.** Your rabbit building should be draft-free for warmth in winter and yet have the option of lots of ventilation for coolness in summer. You can put hutches into almost any kind of ramshackle shelter, and it will probably be good enough for these naturally fur-coated critters. For example, corner poles with cardboard and/or plastic fastened to make sides and roof can work for a while. Don't forget to leave a doorway. For a more proper hutch shelter, screen in the windows helps to keep flies out in the summer.

---

**Water**

Rabbits must be kept supplied with plentiful and clean water. Clean out the water dish regularly, for hair and droppings will get into it. It is important to keep it in a well-roofed place so that droppings from wild birds don't get into it—which could give your rabbits coccidiosis.

**Cold Weather:** In the winter when their water freezes, go out twice a day with warm water to give them a chance for a drink. If their water dish is full of frozen water, you'll have to take it in the house to thaw first, or pour hot water on top to thaw it. The easiest system is to have 2 water containers for the hutch in freezing weather: 1 to be inside thawing, 1 to be outside serving water.

**WATER CONTAINERS:** A good size is ¾ inches deep and 6–8 inches wide. Hanging water bottles, like those pet stores use in gerbil cages, can work for a single, indoor rabbit. They are sanitary but have to be refilled often and can't be used for an outdoor hutch in winter because of the freezing risk. Rabbit water and food containers either must be too heavy for them to pick up and dump over (a favorite rabbit trick) or attached firmly to the cage. Crockery drinking vessels don't rust, are too heavy to be dumped, are easy to clean, and have sloping sides and a rounded bottom that causes ice to rise as it forms instead of staying put and breaking the container. Or you can use the bottom half of a coffee can, or some such, cut down with a tin snips and wired to the side of the hutch so it can't be tipped over. Another homemade waterer is a large pop bottle wired on to hang upside down with its opening in a small can that extends on into the cage. For big operations with hundreds of rabbits an automatic watering system saves hours of time.

**Food**

In the wild, rabbits eat a wide variety of plant foods, but there they have experienced parents to teach them "right" foods from "wrong" foods. Domesticated rabbits depend on their keepers to know the difference. Rabbits have been domesticated for many centuries. The pellet is a very recent invention. So obviously it's possible to raise rabbits on inexpensive, home-grown feed. This does not require great skill in math or an agricultural degree, nor does it take a lot of extra work. Some folks choose to follow the path of home-grown rabbit feed, and they and their rabbits thrive on it. They are rewarded with inexpensive meat, totally free of pesticide residues, which is something you can't get feeding pellets (unless somebody came out with an organic rabbit pellet since I last looked—a great idea that wouldn't be that difficult and would be enthusiastically and gratefully received as would other livestock feeds guaranteed to be free of pesticide-residue.)

**FEEDERS:** You can set hay right on the cage floor or build a "manger" to feed it from. Cages that are in a row can have a built-in common hay manger between each pair of cages. You can set pellets, grain, or other small food in as is or put it in a bowl. Or use commercial metal feeders. Some styles
SECRETS OF RABBIT FEEDING

- Rabbits need a regular feeding schedule: same time each day, same number of feedings per day, and same order in which various feeds are given. Most people feed them twice a day—in the morning and afternoon.

- Rabbits are physically unable to eat fine foods such as a powder or a finely ground “meal.”

- Cut hay-type feed with a hay knife or fine-toothed wood saw into sections no more than 3 inches long for rabbits.

- Rabbits don’t like oily foods. They may enjoy the meal left after oils are extracted—such as from cottonseed, linseed, peanuts, sesame seeds, and soybeans.

- Rabbits are exceptionally vulnerable to insecticide residues on food. Don’t feed them sprayed foods.

- Wash garden foods before feeding them to rabbits because an accumulation of eaten dirt can make a rabbit sick. Slice root vegetables into sticks like carrot sticks. Don’t feed soggy, rotten portions.

- Introduce any new feed—especially a garden one—gradually, by starting to feed a little, then feeding more and more.

- Don’t feed potato sprouts, eyes, or peels.

- Cow parsnip is as good nutritionally for rabbits as alfalfa and can be substituted for it.

- Fresh greens should be clean, cool, fresh but slightly air-dried, and normal colored—not yellowish.

- To store greens for winter rabbit feed: Pick or cut the greens, then sunshine-cure them in thin swaths 2–4 days. They’ll be ready when they’re sun-bleached (a light green color) and dry (but not yet brittle). Pack in stacks or sacks in a dry place.

- Eating spoiled—yellowish or fermented—greens can make rabbits very sick.

- A rabbit on a natural, home-grown diet needs some exposure to sunlight in order for its body to manufacture a needed vitamin.

- It is normal and necessary for rabbits to eat their own night feces. They do this in the late night and early morning hours. Their droppings at this time are different from day ones. They’re soft and light green, while day feces are harder and brown. The night feces are loaded with B vitamins, especially thiamin, which are produced by certain bacteria that live in large numbers in the rabbits’ intestinal tracts. Rabbits eat the night feces to get the vitamins in them. If you prevent a rabbit for 3 or 4 weeks from eating its night feces, it will die of malnutrition.

extend through the side of the cage so you can put feed in from outside the cage without having to open the door. You can make a homemade feeder from the bottom of a metal coffee can. Cut it down to where it’s only about 2 inches high. Bend down the sharp top edge to make it smooth. Punch holes (from the inside toward the outside!) down through the bottom of the can if you are feeding pellets. The useless dust that comes along with pellet feed will sift out through those holes. Make 2 side holes to put a wire through and fasten the feed can to the side of the cage.

**HOW MUCH FEED?** Like dogs and people, rabbits vary in the way they relate to food. Some will take just what they need and just the right foods. Some will eat themselves to illness on a single food, or overeat to a state of obesity if you don’t limit them. Overweight does do have a harder time getting pregnant and have more risky kindlings. Obese bucks may lose interest in mating the does. So you need to keep an eye on their weight. How to tell if your rabbit has a weight problem? Well, the flesh should be firm anywhere on her except the belly, which is naturally flabby no matter what. In fact, the more litters she’s had, the more loose skin you can grab in your hand on the belly of a normal-weight doe. Younger does, like young human girls, are firmer in the belly area. The older doe who doesn’t have some loose tummy skin is the one who needs to go on a diet. Reduce her food amount.

**CONTROLLED FEED AMOUNTS:** About the easiest way to keep rabbits in normal weight is to feed them hay, all they want. Rabbits very seldom overeat on hay. Then just give small, measured amounts of the richer foods, if wanted. Rabbit scientists say the average nonpregnant, nonlactating doe can eat 3.8 percent of her weight each day. For a 10-lb. nonbreeding bunny, that translates to a daily ration of 6 oz. pellets, or 2.5 oz. grain plus 3.5 oz. hay.

Breeding bucks and does get 6.7 percent of their weight: 10.7 oz. pellets; or 3.5 oz. grain plus 7 oz. hay.

Pregnant and nursing does, as well as young bunnies, are generally allowed to eat all they want. The young rabbits maintain that good life at least until age 6 months (or until butchering weight of 4–4.5 lb.). If fed longer, they could weigh up to 10 lb. or so, but after 4 lb. they gain weight slower relative to feed consumption, so they’re costing you more to keep.

**PELLETS-ONLY DIET:** I’ve heard that rabbits raised for meat will gain faster on a diet of rabbit pellets. The bulk of the pellet is a finely ground and pressed together mix of alfalfa hay and a blend of grains. Other minerals and vitamins are added. Pellets have many fans because of convenience. It makes feeding a 1-step operation—no guessing, no need to look around for various diet components and put them into the cage one by one. You can buy them “medicated” or “nonmedicated.” But you still don’t come out money-wise, because of the price of the pellets. Plain alfalfa pellets—which contain no grain—can be used to feed dry does and bucks that aren’t breeding but not breeding males, pregnant or nursing does, or growing young rabbits. Feeding hay and grain is cheaper than feeding pellets, even if you don’t grow any of it yourself.

**HAY AND GRAIN DIET:** A diet of mixed grains provides better nutrition than any single grain. Feed mixed grains (just what combination is up to you) for 30 percent of the rabbits’ diet by weight. Oats, soft wheats, and grain...

</table>

Sorghums are rabbit favorites among the grains. Protein is a small but extremely important necessity in a rabbit's diet. They can get some from grain and some from good legume hay, but they can't get any from nonlegume hay. Chopped grain is better than whole grain, but any grains may be fed whole except barley and oats, which should be rolled, mashed, or ground. Dry corn kernels should be also cracked or some such. Don't get it too small. And don't feed dirty, damp, or moldy grain.

So feed good alfalfa hay for the remaining 70 percent. "Good" hay for rabbits is very leafy, has thin stems, and is clean of mold or dirt. It will smell fresh. This kind of alfalfa hay, if analyzed, would show around 12-14 percent protein. To buy that kind of hay ask for "second-cutting alfalfa." With some grain, or bread, or dairy products added, your rabbit's protein needs will be met. You can serve it in its natural form except that it should be cut into sections less than 3 inches long.

Thus, when you go to the feed store, get a 70-lb. bale of alfalfa hay and 30 lb. of a combination of grains. Another option is the hay—grain diet, plus about 10-20 percent pellets. One lady I know feeds her rabbits ½ lb. of grain and 1 lb. of that legume hay each day.

**Home-Grown Rabbit Food:** The old-timers who wintered their rabbits on food they'd grown themselves fed them such things as stock beets and cabbage in winter as well as their grain and hay. So can you. Pea and bean vines can be cured like hay and make an excellent hay substitute or supplement.

In season, rabbits like anything green, but you must be careful not to feed them plants that are outrightly poisonous, such as chokecherry or rhubarb leaves, or...
potato peels with sprouts or ones that have been in the sun long enough to get even the slightest touch of green. Other greens are only mildly poisonous in the uncooked state such as pigweed, amaranth greens, spinach, comfrey, and Swiss chard—but for a creature with a small body weight like a rabbit, especially a young rabbit, these can be a problem, too. Much of the reason that people develop fear of growing their own rabbit food, or have bad experiences with home feeding of rabbits is because they don't understand how very many greens, wild or domestic, are not fully safe to feed rabbits, and which are. Before feeding a leafy green or herb for the first time, check the list under "Edible for Rabbits," below, to see if there is a warning of any sort about it. Stick to feeding them human-type salad greens unless you know for sure a wild one is safe. If cooking is advised for a green or category of greens (the amaranth family), don't feed it to rabbits who, of course, would be eating it raw. If it's in the least toxic, don't feed it to them. If it might have chemical residues on it, don't feed it to them.

I plant extra rows of lettuce for them. And when I weed in summer, I take along a bucket to put the pulled edible weeds in for the rabbits. Feeding this way you never have to buy a rabbit pellet and they do fine. When fed home-grown stuff, they'll grow a little slower (and more normally) to that 2-lb. butchering size. But it's far cheaper, and I have organic meat because from conception on, they've been nourished with home-grown foods and greens, or hay and grain from a source I know is chemical-free.

Vegetables/Greens/Fruits. A combination of grains is better than a single one. A combination of veggies and greens plus grain and hay is better yet. Let your rabbits do some picking and choosing. They'll choose what they need. They'll love much of what you offer of this sort, and it's a nice way to tame them—hand-feeding some veggie treats. For pregnant and nursing does, variety is especially important. Offer the vegetables or leafy greens in season (the longer the season, the better). Garden and kitchen vegetables and fruit scraps can be included also, as long as they're not on the unhealthy list. If you're just starting to supplement a rabbit's diet in this way, go slowly at first until your bunny gets used to it. Limit what you feed so that surplus doesn't rot in the cage. Rotting surpluses are good for chickens or pigs, but not rabbits. In fact, rabbits can get sick from eating partly spoiled greens. Garden vegetables for rabbits, as for people, are mostly water. Greens are water plus lots of minerals and vitamins. Root vegetables are higher in energy supplied, lower in the mineral-and-vitamin department.

SALT: Rabbits enjoy a salt-and-mineral block in the hutch. They'll lick it for the food value. Rabbits with a block seem less likely to gnaw on their cage. You can just break a chunk off a cow-size salt block for them, or give them a lump of canning salt. But don't give them iodized table salt. Some rabbits prefer plain salt and some like the commercial salt-and-mineral mix.

"BONES" AND "TOYS": If rabbits have something to chew on, they are less likely to chew on wood parts of their cages and generally seem more content. You can combine a chew-on toy with a salt source by soaking a chunk of 2 x 4 in very salty water for about 3 days. Air dry it, and then give it to your rabbit. Rabbits also like to gnaw on a hunk of Sheetrock. They like to knock a tin can around in their cage, but, because they're nocturnal, that kind of play may keep you up at night. In that case give them a toy that won't make so much noise.

Rabbit Reproduction

SEXING: The first thing that can go wrong with rabbit reproduction is having 2 bucks or 2 does instead of 1 of each. In determining the sex, it's easy to make a mistake, especially if you looked when they were young. The younger the rabbit, the harder it is to figure out which is which. If they're less than 2 months old, it verges on impossible. After that age the males get a penis you can see, and maybe testicles too. Once the buck is fully grown his testicles will be easy to see. To sex a rabbit, hold it on its back with one hand. The holding hand also has hold of its tail and is keeping the tail out of the way of where you want to look. With your other hand's thumb and first finger press down firmly but gently around the sex organ. With practice you'll learn the difference between male and female. If it's a buck, the sex organ looks more round; the female's looks more like a slit. As the male gets older, its penis will protrude and be plainly visible when you press and you'll see its testicles.

BUCKS: For a few does you need but a single mature male to keep the supply going. If you have more, you can eat the others. Or you can keep 2—just in case. If you're doing large-scale rabbit-raising, you need about 1 buck per 10 does. Use a buck up to 3 times a week.

BREEDING: Just put the doe into the buck's cage. Don't put the buck in with the doe. It's a fast way to lose a good buck, since the doe will fiercely fight him. This is because the doe has a motherly instinct to be protective of her hutch. After she has lived in there a while, she may attack even if another doe is put in there.

If your doe is not pregnant she will let the buck mount. It happens in a moment—about 1 minute to be precise—and then is over. The buck may tumble over on his side at the conclusion. That's normal and nothing to worry about. In about a minute more he will have recovered and be ready to mate again. If the doe is receptive, you can allow a second mating, but then get her out of there.
and back to her own cage. It’s important to stay there and watch while they’re mating. You watch so you know for sure it happened and that the doe is now pregnant. (Write down the date for future reference. In 30 or 31 days, she'll be a mother.) You also watch so you can remove the doe from the buck’s cage as soon as possible. Don’t leave them alone together. The doe may come to resent the buck’s attention and fight—even injure—him. Or the buck may hurt the doe.

Human women typically ovulate 1 egg exactly midway between the first day of one menstrual cycle and the first day of their next one—the 14th day of an average 28-day cycle. Rabbits, however, don’t ovulate until they have sex, and then they ovulate multiple eggs. That’s rabbit rhythm. (That’s how I got pregnant with Becca. Hadn’t seen Mike for about 6 weeks and then we got back together. Well, it was a rapturous reunion and, even though it was the day before my period was due, I got pregnant. So I can testify from experience that rabbit rhythm can happen to people too!) Because of this, some rabbit-keepers bring the doe back to the buck 6 hours after the first visit to make sure that the eggs she ovulated in response to that first breeding are all fertilized by the buck. **Maternity Cage:** When does aren’t bred, they can room together. But a doe who is expecting needs separate quarters in a pen that provides her with a nesting box and plenty of room for the growing litter: 7 to 8 square feet, minimum. Make sure the door is big enough to get the nest box in and out and that this cage is sized and shaped so that you can reach into all the corners.

**Nesting Box.** The nesting box should be like a separate little room inside the larger cage the doe lives in, with its own top, bottom, and sides. If you don’t provide her with a nesting box, the babies will fall through the wire, and she’ll be so nervous and upset at being out in the open with them she is liable to eat some of them. Fixing her up with the box allows her to pretend she’s in a burrow, and that’s what her nature needs. You can set a wooden box inside the hutch to help to provide her with that soft nesting material even if it isn’t cold. With a good box and plenty of soft working materials with which to build her nest, she will herself create a shelter in which her young can survive even the coldest weather. Also check over the cage, keeping in mind the young rabbits that will soon be romping and exploring in there. For a maternity cage a shared manger isn’t a good idea.

**Dimensions.** Commercial-breed-sized rabbits need a nest box about 12 inches by 18–24 inches and 12 inches tall. There should be a doorway just the right size for the doe to go in and out. The entrance to the box should be raised from 2 to 6 inches off the box’s floor (higher is better, highest is best) so that the blind, helpless young don’t accidentally roll out the doorway. When they have grown big enough to hop over that barrier on their own, they’ll be all right out there anyway. **Kindling Management Day by Day**

**Gestation.** To test for pregnancy you can put the doe into the buck’s cage when she’s supposed to be 2 weeks pregnant. If she stands still and lets him mount her, she probably wasn’t really pregnant. But if you do this “check breed” better be poised to get her out of there at a moment’s notice, because if she is pregnant she’ll fight him. Even if she did let him breed her, go ahead and put in her nesting box because there are does, though rare, that will accept the buck even when they’re pregnant. Another way to test for pregnancy is by feeling her abdomen. The babies inside feel like marbles. The problem with that, however, is that the only way to feel them is to press so hard that you’re likely to harm them. Best not to.

Check the doe for being overweight since an obese doe may die during kindling or deliver dead babies. A too-lean doe is not as much of a risk to herself or her babies. Put her on a diet if needed, early in the pregnancy. A few days of short rations generally does it. Rabbit pregnancy lasts 28–35 days, but most rabbits kindle on day 31 or 32. As her pregnancy progresses, gradually increase the amount of protein you’re feeding. Toward the end, when the babies inside her are growing fastest, let her eat all she can clean up. If she doesn’t get enough food at this stage, some of the babies may die inside her and she’ll abort them. A doe who doesn’t get enough (and nourishing enough) food has a smaller litter. Get her moved into a maternity pen with nesting box well before the delivery date.

**5 Days Before Kindling.** About 5 days before her due date, move a nest box into her hutch. Provide the mother-to-be with ample straw, hay, maybe even some cotton rags if the weather is cold—plus a calm environment. She’ll make those nest-building supplies into just a dandy little nest in there. She’ll pull out some of the fur off her own body to line it. In cold weather, it will help her if you also supply some extra rabbit hair, or wool. (As you care for your rabbits and find bits of rabbit fur, stash them in a paper bag in a dry place.) From those she can make an even warmer nest. Some first-time rabbit mamas don’t catch on in time. If you have one who is failing to pull fur for her nest, it may help to provide her with that soft nestling material even if it isn’t cold. With a good box and plenty of soft working materials with which to build her nest, she will herself create a shelter in which her young can survive even the coldest weather. Also check over the cage, keeping in mind the young rabbits that will soon be romping and exploring in there. For a maternity cage a shared manger isn’t a good idea.
unless it's built so the babies can't possibly crawl into the next-door cage. Make sure there are no holes a little rabbit could fall or crawl through.

From 4 Days Before, Until Kindling. When she is near to her birthing time, keep things around her as quiet as possible and basically just leave her alone. Rabbits are jumpy critters anyway, and even experienced mamas can go hyper around their kindling time.

Kindling: Day 1. First-time mothers are the biggest worry. If she made a nest but doesn't give birth inside it, the babies will die of exposure or fall through the wire. Or she may birth some babies inside, but some outside of the nest. If you find them and they're still alive, there's hope. In that case, old-time rabbit managers rub a chest salve such as Mentholatum or Vapo-Rub lightly onto the mother's nose while she's outside of the nest and gently return the outside babies before she goes back. The rub helps prevent mom's rejection of them by deactivating her smell for a bit.

Check if there's enough fur for a warm nest. If there isn't, add more from your rabbit fur bag.

If a mama at kindling time gets very emotionally upset (it happens easily to rabbits), such as by a dog, or a drastic change in feed, or a water shortage, or too much handling, or just is quirky that way, she may even cannibalize the babies. In that case, give her 1 or 2 more chances to raise a family. If she repeats the crime and she's a stock rabbit, eat or replace her. If she's a pet, then get her to a nunnery for a life of pampered celibacy.

Day 2. If all the babies appear to be in the nest, wait 24 hours and check them on day 2 for the sake of mom's nerves. The babies are hairless, blind, and furless. Get the doe out of there, dab saline on her nose, and go to work on the nest. Count the babies. Rabbits may have as many as 16, but usually fewer. Since most does won't successfully nurse more than 8 or 9 babies, more than that are best fostered out. Remove any dead ones from the nest. Healthy babies are squirming restlessly in there. See if they're nursing well. Well-fed babies have bulging tummies. You can actually see the milk through their thin skin. Check to see if mom's breasts are doing okay. Check to make sure the nesting box is not leaking. It should be absolutely dry in there. Make sure the doe has plenty of nourishing food to eat. Otherwise her babies won't be their largest possible size at weaning time.

Day 3. Check again, as above.

Day 6. Check the babies again. If you find any dead ones—and it happens—remove the bodies.

Day 10. Check again. The little bunnies will be opening their eyes about this time and becoming active and fun. You don't need to supply any food for these young babies. The rabbit is a mammal and feeds her babies milk from her own body until they are large enough to come out and share her feed.

Day 21. The bunnies can start eating something besides mother's milk now. Milk-soaked bread is a good first supplement for them. Very young rabbits have delicate digestive tracts. Be careful. Add new foods gradually, watching for difficulties, just as you do for a human infant. Avoid foods that are harsh in content or texture. For example, oat husks can damage their intestines. To feed home-grown grains to young rabbits, crush them and remove the husks. Bigger young rabbits and their parents like to eat very green, leafy hay, as well as grain.

Day 56. Meat breeds weigh about 4 lb. and are ready to butcher as fryers at this time. Average-sized rabbits, butchered at 2 months, will each dress out to an adequate—for-a-fryer 2 lb. It's definitely time to rebreed the doe. Rabbit lore has it that a doe left unbred for too long may forget how and turn sterile. As for the offspring, there's a very sound reason for butchering at that magic number of 56 days, because if they aren't sent to that fate but rather are left in the cage, you'll have all those little boy and girl rabbits growing together, right? Okay. The simple fact of rabbit life is that an 8-week-old female rabbit housed with a male is about ready to get pregnant and will do so very soon, probably within days. So if you want to keep some of those bunnies to be mothers or fathers themselves, that's the age at which you can start breeding them—or they will start breeding themselves. If that's what you want, instead of butchering them, you give them their own housing, and proceed as above with the cycle of rabbit reproduction. If you want them to continue eating and growing some more but not producing offspring, you had better house the sexes in separate dorms. Unfortunately, the younger they are, the harder it is to tell what sex they are.

Any rabbit you don't want to keep for breeding should be butchered at least by 13 weeks of age, because after that the feed conversion efficiency really goes down.

Orphans: Once I had a mother rabbit jump out of her hut and get killed by a dog when her litter was very young. I saved them by feeding them regularly with milk out of an eyedropper until they were big enough to lap milk out of a saucer like kittens.

Foster Mothers. Another way to handle orphans or babies from a too-large litter is to put them in with another litter of close to the same age. To get the new baby successfully adopted you do 3 things: (1) Lure mom rabbit out of the nesting box and over to the farthest-away end of her cage by feeding something there that she loves enough to give it her full attention for a moment. (2) While she's eating, gently sneak the new baby (babies) underneath those already in the box. The underneath placement is important because there they'll have a chance to pick up their new family's identifying odor before she catches on. Then gently pull the nesting material back over the babies. (3) Get some chest rub on mom's nose before she makes it back into the nesting box and repeat for several days so she can't smell the strangeness of the extras. Even so, some does can't be outsmarted and will just say no.

Rabbit “Vetting”
Rabbits are comparatively healthy and simple to manage as far as their health care goes. If you take good care of them and provide good housing and plenty of nourishing food, you probably won't have much sickness. If you do have sickness, it may be best just to replace the rabbit. They aren't worth what a vet would charge and many vets don't know much about rabbit ailments anyway.

Handling: Never hold a rabbit up by its ears. A rabbit's ears are tender and sensitive. If you are handling a small rabbit (less than 5 lb.), lift it up with 1 hand placed securely under its behind. Lift a large rabbit with 1 hand under it the same way and the other hand grasping the loose flesh at the back of its neck for security. Rabbits prefer to be carried with their head tucked beneath your arm so they feel hidden.
Nail Clipping: Clip to minimize the risk of being scratched by hutch rabbits whose claws are too long. Use a dog-sized nail clipper.

Giving Medicine by Mouth: First get the medicine into an eye dropper. Get yourself seated with the rabbit held firmly between your legs or in your lap. Now put the dropper into the back of the rabbit's mouth. Slowly squeeze the medicine out back there.

Taking a Rabbit's Temperature: Use a regular baby thermometer. Be careful, whether for your child or the rabbit, because those darn glass bulbs break off so easily. Put a little grease on it to make it slide better, and insert only about 1 inch up the rabbit's rectum.

Usually Noncontagious Conditions

Conjunctivitis (Weepy Eye). If your rabbits look like children with pinkeye—with stuck-together, goopy eyes, this is what they have. Use an antibiotic eye ointment and apply once or twice a day. The best ointment is one with an anesthetic so the animals will stop scratching and rubbing their eyes.

NOTE: To prevent conjunctivitis, don't use sawdust for bedding, and keep dust down in the rabbitry.

Hutch Burn/Vent Disease. This resembles diaper rash in that you'll see red and irritated, even scabby places around the rectum and genitals of the rabbit. At worst it's vent disease, which is a very contagious sort of rabbit syphilis. Only your vet can truly tell the difference. Rabbits with vent disease, left untreated, get well from their symptoms and simply become carriers of the sickness, which they give to uninfected other rabbits, or you (wear rubber gloves when vetting).

“Buck” or “Wolf” Teeth. These are genetic (recessive) defects that some rabbits carry. “Buck teeth” are extra long upper incisors. “Wolf teeth” are extra long lower incisors. Eventually, the rabbit can't close its mouth and can't eat normally, and its teeth grow painfully into the flesh. Buck or wolf teeth are hereditary. Don't let an affected animal breed.

Cribbing. Rabbits like to chew. They'll chew on wood in their hutches, even tear holes in their wire. It helps to give them toys to play with, and something okay to chew on, such as pieces of Sheetrock. It also helps to have a salt block in there.

Mastitis. Any milking mammal can get this inflammation of the “breasts.” It can be caused by a bruise or bacterial infection. A doe suffering from mastitis acts listless. Her mammary glands feel hot and swollen. Her temperature may be up. The treatment is an antibiotic. If a doe gets mastitis, her babies are usually taken out of the nest and dealt with like orphans with hand feeding, at least until their mother is well.

Parasites

Coccidiosis. The best approach to rabbit coccidiosis is to emphasize prevention. The disease is caused by wild or domestic birds roosting above your rabbit pens and leaving disease-bearing droppings in the rabbits’ water. This is a good reason for having a roof over the hutch (as well as to keep it cool in summer). Symptoms of coccidiosis in your rabbits are weak, listless behavior; weight loss; pot belly; loss of appetite; diarrhea; thinness.

However, most people don't discover they have coccidiosis disease on their farm until they butcher and find a liver that is filled with white spots. Chickens get it as well as many other kinds of poultry, sheep, and rabbits. The treatment for rabbits is to give them a medicine in their water. Make sure rabbits under treatment are in wire-bottom cages so they don't get reinfected by eating their night feces, which rabbits typically do. Don't butcher for at least 14 days after that treatment.

Ear Canker/Ear Mites. Ear mites are the beasts that cause ear canker in rabbits. Examine your rabbits' ears. If you see brownish discharge and crust, mites are likely the cause. Isolate the infected animals to prevent spreading of the problem, and treat them as soon as possible. After
applying medicine, massage the ear's base to get the medicine well spread. To try to prevent reinfection, use something like rotenone on the pen and the cage. Be careful that you don't spread the infection.

Lice. Fortunately, rabbits don't often get lice—or mange either. If they do get lice, it will most likely happen in winter. A louse infection can be so severe as to make the rabbit anemic, even result in death. A louse powder is the treatment.

Mange. Mange can spread quickly from one animal to another and is not easy to treat. Sometimes diagnosis is difficult. True mange is caused by tiny mites hiding under matted hair. But fungal or bacterial infections can resemble mange. A vet can identify mange by examining a skin scraping. If you suspect mange, an organic response is to butcher the animal and burn its pelt because treatment involves insecticide, costs money, and is likely to not be successful at least the first time. An animal with mange is a source of infection to other animals.

Fungus Infections. Commonly known as "ringworm." Some rabbit-keepers immediately isolate, even kill and burn or bury any infected rabbit. To treat, cut the hair around the infected area quite short and apply fungus powder or ointment (wear rubber gloves). Sun shining on the affected area can help also.

Worms. Rabbits can get them—most usually the tapeworm—from other farm livestock, dogs, cats, birds, or rodents. Tapeworm can spread by infected cat or dog manure getting into rabbit cages or feed. A rabbit with tapeworm has dull fur and maybe blood or mucous in its droppings. For suspected worms, you can take the rabbit and a droppings sample to your vet, who will examine the feces under the microscope and know for sure. However, there's no treatment for tapeworm that wouldn't kill the rabbit, too.

Rabbit Butchering

Rabbit meat is the leanest of all nonfish meats—and delicious! It is often compared to chicken, but each has its own distinct flavor and texture. After all, one is a mammal, the other fowl. Precise weight at proper butchering age varies wildly because rabbits' weights can vary so much according to breed, sex, and age. The meat you end up with will be about half the live weight. Young rabbits are distinguished by their soft ears and paws—stiffness is a sign of age. An old rabbit can be stewed like an old chicken. Rabbit meat is almost fat-free.

**Keeping Records**

<table>
<thead>
<tr>
<th>If you want to make a profit on any livestock, you need to keep records. Some people scribble in a notebook or on a calendar. Some have slick computer systems. If you have caged rather than communal rabbits, you'll want to note breeding and kindling dates. That way you can have nest boxes available on schedule. A good system is 1 page for each rabbit and on that page you answer the following questions:</th>
<th>7. Were there any birth defects?</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. What's the animal's name?</td>
<td>8. How many were weaned?</td>
</tr>
<tr>
<td>2. How many were in the litter it was born into?</td>
<td>9. What date were they ready for butchering?</td>
</tr>
<tr>
<td>3. Who was it bred to?</td>
<td>10. How much did they weigh?</td>
</tr>
<tr>
<td>4. When did it give birth?</td>
<td>11. How many of them were does? Bucks?</td>
</tr>
<tr>
<td>5. How many were born? Alive? Dead?</td>
<td>12. Did you choose to keep any of the litter for future breeding stock?</td>
</tr>
</tbody>
</table>

**Killing:** Some recommend that you first stun the rabbit with a hard blow on the head, right behind the ears, then chop the head off on your chopping block as close to the head as possible. Other rabbit owners find it very difficult to get a well-placed, effective blow in and prefer to begin by snapping the animal's neck by stretching it with the hands.

To do that, hold the rabbit's hind legs about chest-high with your nondominant hand (the left for me) and hold the rabbit's head firmly around the neck with your dominant hand. With the dominant hand you are now doing 2 motions at once: pulling the body down in tension against your other hand's grip, and bending the rabbit's head up and back as far as possible at the same time as you pull its body down. Keep pulling the rabbit's head up and back with a steady, firm motion until you feel the neck break.

Then proceed, as above, to cut off the head with an ax on a chopping block, or with a sharp knife, cutting through the spinal-column cartilage. To get the rabbit properly bled out, hold it upside down for a few minutes, or hang it. (You can save a mess by catching the blood in a garbage sack).

**Hanging:** Now prepare the animal for skinning (if it has not already been hung) either by nailing the 2 hind feet about body width apart to a board or skinning table, or by hanging it up. The hanging procedure is the same as that used with larger animals. Cut the skin off just toward the body from the hock joint of each hind leg and peel it back enough to expose the 2 Achilles tendons. Insert the hooks, ropes, chain, or whatever between the bone and Achilles tendons just above the hocks. It will be handy if you have ready a gambrel (hook), suspended about chest high. You can make one out of a piece of stiff wire about 1 foot long. Make a hook at each end to hook the exposed Achilles tendons of the rabbit (which are strong enough to hold the animal's weight even under considerable pulling pressure) and suspend from a tree branch or some such. Or a rope thrown over a tree branch with a hook at each end will work. Or you can just tie a couple loops around each leg las shown in the illustrations.

**Skinning:** With the rabbit on the gambrel, you cut off the front feet and the tail. (Later, you can give the tail to the children to enjoy.) Split the skin between the legs with a very sharp small knife. Start with the hock joint on the inside of one hind leg, cut down to the crotch of the rabbit and the back up the inside of the other hind leg to the other hock joint. Cut the skin from each front leg to the neck. (Do not cut down the belly centerline at this time.) Then peel then skin down off the body, beginning at the hind hocks, like...
you would take off a banana peel or a sock. Cut around the anal opening and any place the skin is not coming off freely. Pull the skin off like that, inside out, clear down to the front feet, and then it will be completely off. If you have taken the skin off cleanly, you may want to use the very soft rabbit fur. See “Tanning” in Chapter 8.

**Easy Skinning.** If you don’t care about the skin, skinning is easy. Just hold the rabbit by a hind leg and with your other hand pinch the hide at the hock joint and pull downward. The skin will tear at the point of the pull and you can peel it off without a knife. Or remove the head and feet, then pinch up the hide in the middle of the back and cut through it with a knife. Then grasp the hide on either side of the cut and pull in opposite directions. Pull the front half toward the head and the rear half toward the tail. Peel the skin off, rolling it down over the legs. Cut off the head, feet, and tail, and you’re done with that.

**CLEANING (“DRESSING”):** You may either take the animal off the skinning board or down from the hanging position and place on a cutting board, or continue to work it where you already have it. Cut around the anal vent and down abdomen. Remove innards.

**Cutting it Up:** First, cut off both front legs at the shoulder joints and both hind legs at the hip joints. Cut through the ribs on both the left and right sides, parallel to the backbone, to cut free the breast piece of the rabbit carcass. Divide the remaining back piece into 2 or 3 pieces (depending on how large the rabbit is and how large you want your pieces). The big meat pieces are found on the hind legs and the haunches (loins) where they are easy to cut from the body. The loin pieces are the choicest on the rabbit, great for stews. It’s a good idea to bone the thigh, leaving the shank intact. The forelegs of a rabbit have very little meat and are better off in the stock pot.

**Freezing:** Washed and chilled rabbit or cooked rabbit can be wrapped in plastic freezer bags or freezer paper. If you are including gravy or sauce with cooked rabbit, pack it in plastic containers with tight lids. Fresh rabbit will keep in the freezer for 4–6 months, but use the frozen cooked rabbit before 2 months. Thaw rabbit in the refrigerator and never refreeze. It will take up to 16 hours to thaw a whole rabbit, but smaller pieces will be ready in 4–9 hours. Or you could be modern and put it in the microwave—and be done in a jiff.

**Cooking:** Fry, boil, bake, roast, or barbecue the rabbit meat, or grind it for rabbit burger or rabbit sausage. Frying is the most common cooking method. Many recipes ask for rabbit meat to be browned. This can be done in a hot skillet for a few minutes then evening out in the oven at 350°F for 5–8 minutes. To preserve rabbit meat, freeze it, can it, or make jerky. Although almost any chicken recipe (and some for veal, too) can be adapted to rabbit, keep in mind that rabbit meat is very lean and delicate. Don’t over cook it or let it dry out. To can rabbit, use directions for chicken.

**Oven-Fried Rabbit** Brush pieces of 1 rabbit with ¼ c. melted butter or margarine. Sprinkle with salt and pepper and place in a flat baking pan. Cover with foil or a tight-fitting lid and bake at 350°F for an hour or until tender. Occasionally brush on more butter or margarine until the top is light brown.

**Buttermilk Rabbit** Place your rabbit pieces in a casserole dish. Pour 2 T. melted butter over 2 c. bread crumbs, and spread the buttered crumbs over the rabbit in the casserole dish. Add salt, pepper, and paprika, if you like it. Cover rabbit and crumbs with 2 c. buttermilk. Top with 3 bacon strips. Bake at 350°F for 1½ hours.

**Sour Cream Rabbit** Cut rabbit as for frying. Brown in butter. Add 2 c. sour cream, and simmer until tender. You can
season with salt, pepper, minced onion, and parsley that has been cooked in butter 2 minutes before being added. Add a little cayenne, if you like things hot.

**DORIS'S RABBIT STEW** Cut up rabbit. Dredge in flour. Brown all sides. Fry until tender. Cool. Remove bones and chunk meat. Dice white potatoes and cook with thinly sliced carrots. Season. When partially done, add peas, parsley and sliced onions. Cook very slowly for 2 hours. Now take your skillet with the rabbit drippings (where you previously fried the rabbit) and make a light gravy. Pour this over your done, but not too juicy, stew. Add 2 T. butter and finish seasoning, if needed. This eliminates all wild taste in rabbit.

**FRIED RABBIT** If the rabbit is very big, boil 10 minutes, drain, and then proceed when cool enough to handle. Dip in egg, then in crumbs, and sprinkle with salt (or into salted flour) and place in hot frying pan that contains plenty of fat. Cover and get the rabbit well done on the first side before you turn it to brown on the other side. If you want to make gravy, 1 c. of milk or cream will go well in it.

**RABBIT AND BISCUITS** Cut up the rabbit, cover it with cold water, and put it on to boil. Add 1 t. salt and cook until tender. Have biscuits ready (buttermilk biscuits are wonderful). Break open a biscuit on each plate. Put a piece of rabbit on the biscuit. Thicken a reasonable amount of the broth with flour; add 1 c. of milk or cream, stirring, and pour some over each piece of rabbit and biscuit. Serve at once.

**ROAST RABBIT** Stuff the rabbit with a regular stuffing or line with sausage. Sew up and truss the shoulders and legs closely to the body or they'll come to a crisp. Rub the skin with butter, add a little water to the pan, and baste often with butter unless you are using a Dutch oven with a tight-fitting lid. Make a gravy of the drippings with a little currant or wild plum jelly added and serve with mashed potatoes.

**BARBECUE SAUCE RABBIT** Brown your cut-up rabbit in a heavy frying pan that has a lid. Make a barbecue sauce of 1 t. salt, pepper to taste, ½ c. water, 1 small onion (chopped), a shake of garlic powder, ¾ c. tomato paste, ½ c. catsup, ¾ c. brown sugar, ½ c. vinegar, and 2 T. prepared mustard. Pour the barbecue sauce over the browned rabbit, put the lid on the pan, and bake in a 350°F oven until done (an hour or so).

**POTTED RABBIT (OR CHICKEN)** Brown meat in small amount of oil in skillet or Dutch oven. Add onions, tomatoes (stewed or fresh), wine, mushrooms (if on hand), and carrots or other vegetables as desired. Cook until tender and sauce is thick.

These recipes are from Nancy Cramer, Kent, WA:

**BASIC SWEET AND SOUR SAUCE** Dissolve 1 bouillon cube in 1 c. boiling water. Add 2 T. vinegar and 1 T. brown sugar. Heat. Thicken with a flour and water paste (thin) or whatever to desired thickness. Can be used with baked chicken or rabbit.

**RABBIT AND DUMPLINGS** These are even better than chicken and dumplings. Cook rabbit pieces in water (almost to cover) with salt and a bay leaf until tender. Remove bay leaf. Forty-five minutes before serving, add 2 large onions and 4 or 5 (however many you need for your family) carrots in thick slices (⅝ inch or thicker). Also add a couple of pinches of sweet basil and parsley. When done, drop dumplings (any recipe) on top and cook until done—enough to avoid gumminess. I like dumplings best that rest on the meat and vegetables, sticking partly above water to cook. But you can make good dumplings in a broth too. When dumplings are done, fish them out with a slotted spoon. Serve dumplings and rabbit in one bowl, the carrot and onion mixture in another. Thicken the remaining broth with flour to make a gravy to serve over dumplings. Makes a nice one-dish meal.

**BUNNY SAUSAGE** You'll need 6 lb. uncooked rabbit meat, ground; 2 small onions, minced; 2 level t. salt; 2 level t. pepper; ½ t. ground cracker or bread crumbs; ½ c. milk; ½ t. paprika; 1 bay leaf; ½ t. ground sage; and 1 or 2 eggs, well beaten. Mix the ingredients well together. Mold into small cakes and fry until nicely browned.

**CANNED OR FROZEN BUNNY SAUSAGE** Pack sausage into clean canning jars to within 1 inch of top of jar and add 3 or 4 T. of the grease in which the cakes were fried. Put on the cap, screwing the band tight. Process according to regular directions for meat. Or you could freeze it.

**RABBIT SANDWICH SPREAD** Mix together 1 c. cooked, cooled, boned, and ground rabbit meat with ½ t. salt. Add mayonnaise or salad dressing as needed to moisten. If you want a spicier spread, add a pinch of white pepper, celery salt, or a seasoned salt. This is great on toast.

**SHEEP**

Sheep are grand lawn mowers and land fertilizers and are far less likely to damage your trees than goats are. A lamb is a cute pet that will delight any child's heart. "Lamb" (young sheep) is delicious, healthy meat. Ewes are mellow creatures to have around, and rams are pretty good as herd males go if they were treated kindly while young and were naturally mothered rather than bottle-fed. Sheep are easier to handle and transport than horses and cows. A small flock of sheep is a relatively easy livestock project for a beginner. If you have a well-fenced pasture with a minimal shelter for them, they require only a few moments a day of feeding and watering time—except during lambing and weaning.

They produce a wool crop as well as a meat crop, both of which can provide cash income. If your choice is between sheep and beef calves, consider that sheep aren't as expensive to buy as cattle. It is possible to milk them, and their milk makes good cheese. You can feed about 7 or 8
sheep on the amount of pasture that could support only a single cow. The meat crop will be ready 6 months after birth, instead of the year and a half it takes to get a calf to slaughter size, and the smaller animal will be easier to butcher. A general rule-of-thumb is that—in dressed meat—8 sheep equal 1 cow.

Sheep can get most cattle or goat diseases, but they are more able to survive them, and they get fewer diseases than pigs. If sheep fall in a stream, they often can’t get out because their wool gets waterlogged. They are more susceptible to predators than the other large stock. Huge flocks of sheep in the mountains in the spring.

Sheepherders caring for a flock of sheep on a big, open range are a very special sort of people—not cartoon characters. There are lots of jokes about them, but they are real people, working a difficult and desperately lonely job in the mountains for low wages.

Getting Started
In general, learn as much as you can before you get started, and then begin on a small scale.

American Sheep Industry Association offers market, legislative, news, links, etc.: 303-771-3500; 6911 S. Yosemite St., Ste. 200, Englewood, CO 80112-1414; info@sheepusa.org; www.sheepusa.org.

Black Sheep Newsletter is a great quarterly for small-flock and colored-sheep owners. $14/yr in U.S.; $18 outside U.S.; 25455 NW Dixie Mountain Rd., Scappoose, OR 97056; 503-621-3063; bsnews1tr@aol.com; www.blacksheepnewsletter.com. They also offer The Black Sheep Newsletter Companion: Writings for the Shepherd and Handspinner, a collection of the first five years of the magazine, and a lamb cookbook.

Montana Sheep Association offers it all: a terrific website with news, an online magazine, and a supply sales catalog! 406-442-1330; www.mtsheep.org.

Sheep! gives practical advice for small flock owners, articles for small and commercial flocks on wool and related issues, plus an extensive breeders’ directory and listing of breed associations and a regular feature on dairy sheep. It costs $20 for 10 issues/yr. Contact: 920-648-8285; fax 920-648-3770; PO Box 10, Lake Mills, WI 53551-0010; www.sheepmagazine.com.

The Shepherd, a monthly magazine for both small and commercial flocks, costs $20/yr: 419-492-2364; 5696 Johnston Rd., New Washington, OH 44854; shepmag@brightnet.com.

Books: For sure, get a copy of More Sheep, More Grass, More Money, an 112-pg book by Peter Schroeder, owner of a large commercial sheep flock in Manitoba (available from Sheep! Magazine, $10 postpaid). The long-time (now updated/revised) classic is Storey’s Guide to Raising Sheep, by Paula Simmons and Carol Ekarius. It includes breed descriptions, info on predators, herding with dogs, health, etc. Sheep! magazine often has pages listing books on sheep production. Other useful books are The Sheep Raiser’s Manual by William Kruesi (1985); Sheep: A Complete Owner’s Manual, by Gunther Marks (tr. from German and very good); and The Sheep Production Handbook, a comprehensive text from the ASI (1990) (303-771-3500; www.sheepusa.org).

ATTRA’s booklet, “Sustainable Sheep Production,” is at www.attra.org/attra-pub/sheep.html. Maryland Small Ruminant Page is a great website info center for both sheep and goat growers with articles plus links: sheepandgoat.com.

Supplies
Sheepman Supply Company provides a wide range of supplies to sheep farmers, including shearing gear, health care products, books, and videos. Free catalog: 800-331-9122; 301-662-4197; fax 301-662-0361; PO Box A, Frederick, MD 21702; info@sheepman.com; www.sheepman.com.

Wiggins & Assoc. offer a nurser bucket for lambs, etc.: 800-600-0716; www.wigginsinc.com.

Vocabulary
Lamb—a young sheep
Bum—a bottle-fed lamb
Cosset—another name meaning bottle-fed lamb
Ewe—an adult female sheep, pronounced “you”
Ram—an adult male sheep
Wether—a castrated male
Yearling—sheep that’s around a year old

Breeds of Sheep
Breeds of Sheep: Marilyn Jones wrote a classic to help you sort them out: Breeds of Sheep, available from her
at Jones Sheep Farm, 1556 E. 59th, Peabody, KS 66866. Or go to Oklahoma State U.’s livestock breeds page: www.ansi.okstate.edu/breeds/sheep.

What do you want the sheep for? Pets? To keep your grass mowed? To raise meat for your table—or to sell? To show at the fair? For sheepskins or leather? Or to grow wool that you will shear, card, and spin?

Do you want fast reproduction? Finn sheep have 3–6 babies at a time. But be careful you don’t let a Finn ewe get bred by a ram of a larger breed. It could result in dead babies or a dead mama. Or do you want naturally polled or horned sheep? (Dorsets come either way.)

You do want always to select “open-faced” sheep, on which the wool naturally does not grow around the eyes. “Wool-blind” sheep can’t avoid predators because their wool actually grows down their faces onto their eyes. So even in a wool breed you want an open face. Otherwise you must periodically clip around the sheep’s eyes.

And what about personality? Breeds differ and individual sheep differ. Choose a style that suits you. A calm and pleasant disposition is easier to live with than a tense or aggressive one. On the other hand, Mouflon sheep are the only breed that is said to protect their young aggressively from predators, and that’s good.

Crossbreeds. In the United States there are 9 major breeds of sheep—many of which used to be crossbreeds but now have become accepted as breeds in their own right—and innumerable crossbreeds. There are more people doing homestead-level independent and experimental cross-breeding with sheep than with any other farm species. They are frequently selecting for particular wool colors, but many other characteristics can be selected for also. Unless the crossbreed is obviously a real winner and a sheep of the future, crossbreeds may be less expensive than purebreds.

Wool Breeds. If your interest is wool, what climate do you live in? Fine-stranded wool (from the merino breed of sheep) traditionally comes from breeds suited to warmer climates like Spain. Medium-stranded wool breeds live in the temperate zones like England. The coarsest grades of wool (Lincoln breed of sheep) are associated with the cooler, damper climates. “Coarse” wool means a thick strand. Coarse wool spins faster for hand spinners than fine wools. In any case, when buying sheep for wool, look for a pink skin and a dense coat. A good wool breed like Corriedale should provide you about 10–14 lb. of wool per clipped ewe. (Enough to knit 2 sweaters.) A nonwool breed such as the Suffolk will produce only about a 5-lb. fleece. (Finns come with 8–10 lb.)

Homespun wool has more life and strength than commercially spun wool. It has water-resistance, manageability, flexibility, durability, and warmth. You can choose your wool according to your purpose since wool from different sheep breeds can be quite different stuff, varying in length from 1½ to 10 inches, and in number of crimps per inch, from ½ to 30. Fine wools (such as Rambouillet) yield a softer product (suitable for a baby’s blanket, for example), but are more difficult to spin. Coarse fibers (such as from Karakul or Lincoln sheep) spin more easily into a very durable product, such as a rug. Coarse wools are considered too itchy to be made into clothing that would be worn next to the skin. The medium wools (Hampshire, Suffolk, Cheviot), with fibers averaging 3–4 inches long, stand between these 2 extremes. They are manageable for beginning spinners and can be made into blankets, sweaters, and fabric for other clothing.

Wool Colors. White sheep wool is the standard. Black wool is discounted in regular markets but more valued in specialty spinners’ outlets. Black sheep wool can’t be dyed. White and silver wool mixed comes from an old black sheep and can be dyed. Wool in other natural colors, other than white, is of interest only to hand spinners. But there are lots of hand spinners! Get more info from the Natural Colored Wool Growers Ass’n: Barbara Kloese, Registrar; 219-759-9665; 429 W. US 30, Valparaiso, IN 46385-9207; kloese@gte.net; www.ncwga.org. And from American Black Sheep Registry: 4714 Glade Rd., Loveland, CO 80538; hmerino@concentric.net. And the Black Sheep Newsletter (see “Getting Started”). If you want white, then make sure your sheep has no dark fibers mixed in. Suffolks are a black-faced sheep with white wool and the most common registered sheep. They usually have a little black color matching their faces around their lower legs but no wool around their lower legs so they have cleaner, dainty looking feet. Hampshires are second most common, followed by Corriedales. Dorsets are all white, available either polled or horned, and are considered to be exceptionally good mothers. Karakul and Corriedale sheep are white sheep with a higher quality wool for hand spinning that you can get a premium price for.

Meat Breeds. Meat breeds have wool, too, but they are also bred for good meat production. Suffolks, Columbias, and Shropshires are good meat-wool breeds. Don’t think that just because a breed is noted for good meat carcasses, it isn’t also fine for wool production. Suffolks, for example, grow a nice spinning wool.

Milk Breeds. You can use sheep for milk. Sheep often have conveniently short teats and a limited lactation period, and younger ones hate to stand still. But their milk tastes good, and it makes wonderful cheese with a dense curd. Try some Romano and see! Sheep don’t give as much milk as goats. American sheep produce 1 pt. to 1 qt. of milk a day, but French dairy sheep give up to 3 qt. per day, so Americans are working now to upgrade their sheep dairy herds for productivity. Nevertheless, pound for pound, a sheep’s milk will give you 2 or even 3 times more cheese than a cow’s milk because it’s that much higher in solids. Sheep butterfat is also different in a good way although there is twice as much of it; it’s 45 percent polyunsaturated fat. Sheep milk is richer in calories than cow’s milk. It provides much more calcium, riboflavin, and thiamin. With all this good stuff in it, don’t be surprised that it’s yellower and thicker than cow’s milk. Sheep milk is naturally homogenized because of the sort of fat in it, even harder to make butter from than goat milk, but it makes super ice cream and yogurt.

Cheesemakers’ Journal regularly offers good articles on sheep dairying such as “Sheep Cheeses,” “Milk Production in the Ewe,” and “Yoghurt from Sheep Milk,” in issue 18/19; “Sheep Dairying” in 24; “Sheep Cheesemaking in Poland” in 25; and “Sally Jackson of Washington State—Sheep Milk Cheeses” in 30 (available from 413-628-3808; www.cheesemaking.com). Yves Berger is the shepherd at the U. of Wisconsin’s Spooner Research Station, working on dairy sheep research: 715-635-3735; W6646 Hwy. 70, Spooner, WI 54801.
David Major organized a group of Vermont folks to milk sheep. He now makes Vermont Shepherd, a sheep's milk cheese, in his curing cave from wheels of week-old sheep cheese that farmers bring him: 802-387-4473; 875 Patch Rd., Putney, VT 05346; vtsheprd@sover.net; www.vermontshepherd.com. Willow Hill Farm (www.sheepcheese.com) also makes sheep's milk cheese. Sheep cheeses are common in Europe but a fairly new industry here. Roger Steinkamp is president of the North American Dairy Sheep Association, and also a sheep cheese maker in Hinckley, MN. Roquefort, feta, and kasseri are all made from sheep milk, as is Italian-style Romano.

Sizes. Sheep come in different sizes. Bigger sheep require more feed and you can pasture fewer per acre. I've heard that smaller sheep actually produce more meat per acre of pasture, but I don't know if it's been proven.

Specific Breeds. There are so many breeds of sheep, I can't give you info on all of them, but here's a good start.

Border Leicester: American Border Leicester Association, Nila Swzeda, Registrar, PO Box 162, Crown Point, NY 12928; hilltop@bluemoo.net.

Clun Forest: North American Clun Forest Association, 21727 Randall Dr., Houston, MN 55943; 507-864-7585; Bramble@acegroup.cc; www.clunforestsheep.org.

Coopworth: Sheep Society of North America, Marcia Adams; 360-297-4485; 25101 Chris Ln. NE, Kingston, WA 98346; rainfarm@tscuet.com.

Corriedale: American Corriedale Association, Marcia Craig, Secy., PO Box 272W, State Rt. 182 E., Upper Sandusky, OH 43351; 740-482-2608; cumbiasheep.org.

Cotswold Breeders Association; Tony Kaminsky, Registrar; 410-374-4383; fax 410-374-2294; PO Box 441, Manchester, MD 21102.

Damara “fat tail sheep” are called “low maintenance meat sheep for mowing, weeding, and fertilizing”: (07) 5464-0533; www.damaras.com.

Friesians are European dairy sheep that arrived in the U.S. in 1996. They’re available from Willow Farm. wsmart@together.net. Or contact the North American Dairy Sheep Ass’n. c/o Tanya Gendreau; 608-582-2476; N20712 Thompson Lane, Galesville, WI 54630.

Icelandic sheep are available from Susan and Rex Mongold, Tongue River Farm; 406-232-2819; HC 40 Broadus Stage, Miles City, MT 59301; trf@mcn.net; www.ice landicsheep.com.

Jacob Sheep Conservancy Registry and Breed Association, 1165 E. Lucas Rd., Lucas, TX 75002; 972-727-0900. Or PO Box 10427, Bozeman, MT 59719; spotted sheep@yahoo.com.

Karakul: American Karakul Sheep Ass’n; Leslie Johnson, 405-771-3072; 7001 N. Air Depot, Oklahoma City, OK 73141. Or Letty Klein, 616-381-0980, evenings; Pine Lane Farm, 6881 N. 25th St., Kalamazoo, MI 49004. American Karakul Sheep Registry: 660-838-6340; fax 660-838-6322; 11500 Highway 5, Boonville, MO 65233; AKSR@mid-mo.net; www.karakul sheep.com.

Lincoln: National Lincoln Sheep Breeders’ Ass’n; Roger Watkins, Secy.; 1557-173rd Ave., Milo, IA 50166; 515-942-6402.

Merino: The American and Delaine-Merino Record Ass’n can provide breeder listings (AK, Canada, most states), detailed info on the breed, and registration paperwork: c/o Elaine A. Clouser, Secy.; 419-281-5786; 1026 Co. Rd. 1175, Rt. 3, Ashland, OH 44805. This breed, first developed by the Spanish from the 14th through early 19th centuries, is now raised also in America, Australia, Russia, and South Africa. Both polled (hornless) and horned varieties are available. Rated as a medium-sized sheep (rams 175-235 lb.; ewes 135-180 lb.), its “productive lifespan” is 10+ years. Merinos have a tendency to stay together (easy to herd), ability to breed out of season (lets you decide when lambing will happen), and very fine wool. Twins 50 percent of the time. Lambs weigh 100-120 lb. in five months.

Montadale Sheep Breeders Association, PO Box 603-H, Plainfield, IN 46168; 317-839-8198. Mary HaWaaboo has bred Montadales for 15 years at 3710 A St. SE #3, Auburn, WA 98002; 206-714-3257.

Navajo-Churro Sheep Association: Connie Taylor, Registrar; 505-737-0488; churro@taos.newmex.com; Box 94, Ojo Caliente, NM 87549.

Rambouillet: Bluestem Farm is where Walt & Wanda Martens raise both white and natural-colored Rambouillet: 502 Cash Spring Rd, Ozark, MO 65721; 417-581-7489; bluestemfarm@hotmail.com; www.bwoolmercantile.com.

Romanov: North American Romanov Sheep Association, 614-927-3098; Don Kirts, Secy., PO Box 1126, Pataskala, OH 43062.

Romney: American Romney Breeders Ass’n offers quality fleeces on large-framed sheep: www.americanromney. org. Larry & Gail Bullock have raised purebred white and natural-colored (range of black to oatmeal or champagne colors) Romneys for 20 years: 360-825-5613; 38815-272nd Ave. SE, Enumclaw, WA 98022; lgbullock@aol.com; www.bullockromneys.org.

**WHERE TO BUY:** You are probably best off buying out of a healthy-looking flock nearby, so that you can drive the animals home yourself. Auction sheep are generally cheaper, but they may be the culls from somebody's flock, going by fast enough that you don't have a chance to find out their problems until too late. It's safest to take your time, take a sheep-knowledgeable friend along, and buy from a reputable breeder. If you want to show at a fair or to go into serious breeding, then you want to buy purebreds from an appropriate breeder.

**NUMBER OF SHEEP:** You will need to get more than 1 sheep or provide some other companionship because they're herd creatures by instinct. A sheep can be content in a field with a pony or even goats, but a lonely sheep will be miserable and annoy you by bleating all the time. At the other extreme, the more sheep you have, the more sheep problems you have; in other words, a small flock is easier to care for than a big one. A typical-sized year-round family flock consists of 6 or 7 ewes. A good way to get started is to buy ewes that have been recently bred in the fall. After lambing every spring, you'll have the extra lamb population for your good grass season until the fall when your lambs will be sold, butchered, or kept to increase your herd.

**AGE OF SHEEP:**

- **Bum Lambs.** You may be able to get a couple of tiny, bottle-fed lambs for a small price, feed them milk until they can be weaned to grass, then butcher them in the fall, or keep them for breeding. If you have goats or cows and thus plenty of cheap, surplus milk (and children who will be enthusiastic about doing the work), this can be an economical way to get started. If you have to buy the milk, even using a special product from the animal feed store, it can get expensive.

- **Weaned Lambs.** This is the easiest, least risky system of acquiring sheep as far as animal problems go. Start by buying a couple of weaned lambs. They'll be several months old as compared to the day-old bummers, past the risky stage for scours, and well started on a grass diet. If they are strictly for meat, you get them in the spring, pasture them all summer, and butcher them in the fall when the grass dies back. Or you could keep them for breeding stock. The problem with starting with yearling breeding stock is that they are slightly more likely to have difficulty lambing, and they may be reluctant to let their babies nurse—even reject them completely, which you can deal with when you have experience, but it is more difficult to handle when you're all learning together.

**Pregnant Ewes.** In the fall—October or November—buy pregnant 2- or 3-year-old ewes that have experience with lambing. When you buy them, be sure and ask the seller when they got bred; you need to estimate their lambing date. Feed them through the winter and lamb them out come late winter; by spring you have a sizable flock. Odds are for every 2 ewes you have, you'll get 3 lambs because of common twin or even triplet births. This is considered a relatively cost-efficient way to get started.

Whatever age sheep you start with, if you buy from a nearby breeder that you feel good about, you'll have somebody to go back to with future questions. In general, look for a large animal compared to others of the breed, with proper conformation if you're buying registered, and good health. Here are signs of poor health:

- **Teeth.** An experienced sheep person can capture a sheep, gently lay it down, open its mouth, pull down its bottom lip, and see what shape its teeth are in. The teeth in a sheep's mouth tell its age. A lamb has 8 "milk" teeth—and they're all in its lower jaw. Somewhere between 12 and 18 months the center pair will be replaced by the sheep's first pair of permanent teeth. You can distinguish permanent teeth from the milk teeth because they're longer and wider. A 2-year-old has 4 permanent teeth. A 3-year-old has 6. A 4-year-old has 8, and that's the most it will get. In the 4-year-old sheep's mouth, all the baby teeth are replaced by the permanent ones. A sheep with those 8 permanent teeth has a "full mouth." The usual sheep produces well until its 6 or 7 years old and may live until age 12, although after age 6, it's considered to be getting "old." As the sheep continues to get older its teeth gradually slant forward, spread out, grind down, even break off. A "broken-mouth" sheep, meaning one with teeth broken off or missing, is past its prime and not a good buy. If it lives long enough, all the teeth will be gone; that's called a "gummer."

- **TRANSPORTING SHEEP:** You can move a sheep in the back of a pickup. Simply lift it up there! If the pickup bed has side racks, you can leave it loose in there. If the sheep is halter-broke, you can put a halter on it and tie the halter rope to something in the pickup bed. Or you can tie the sheep's legs so it can't walk and transport it that way. When moving sheep, you'll notice what size your sheep is. Transporting is one time you'd be glad for a smaller breed over a larger one.

**Foods and Feeding**

**PASTURE**

**What Plants Are in Your Pasture?** Ask your county extension agent if there are local plants that poison sheep, like lambkill or ragwort. Learn to identify them, and find out how other area growers avoid losses from them. Don't require sheep to clear out brush; that is a job for goats. On the other hand, be open to the possibility that a herd of sheep might well clean up a particular weed problem you have—for example, knapweed. This nasty green pest takes over very fast, kills off the other plants, reseeds itself generously, is a perennial, and is resistant to herbicides. But
When to Turn Them Out

Burdock growth because its seed hulls are nearly impossible wool relatively easily. Straw that has been chopped, wood weeds are a kind sheep thrive on, such as knapweed. it. But sheep that have not been on pasture, when freshly select straw with long strands—it can be cleaned out of the ground level. Get to it before the plants have a chance to become a problem to the spinner.

Chickens, however, will enjoy your thrown-away plants. Thistles, fleabane seeds, Spanish nettles, even the tiny timothy and bluegrass seeds, will be a problem if they get into the wool. (Chickens will enjoy all these discard plants.) Some people mow their pasture twice a year to keep weeds down. Some people bundle their sheep in actual jackets!

When you provide bedding for the sheep, it’s best to select straw with long strands—it can be cleaned out of the wool relatively easily. Straw that has been chopped, wood chips, or sawdust all tend to get into the sheep’s wool and become a problem to the spinner.

When to Turn Them Out. Some owners wait until the grass is 3–4 inches high before turning the sheep out to eat it. But sheep that have not been on pasture, when freshly turned out to it, may temporarily get loose bowels. It helps to give the sheep and lambs a generous portion of hay in the morning before you turn them out on the green grass the first time.

How Many Sheep? You can put out as many as 6 (or more!) ewes, plus their lambs, per acre if you have top-notch grass; 4 per acre if you have poorer grass; maybe only 2 if the pasture is full of brush and weeds, unless the weeds are a kind sheep thrive on, such as knapweed.

Rotating Pastures. This helps prevent worms. The easiest way to set up pasture rotation is to divide the pasture exactly in half. (Provide water on both sides.) When the grass on one side is eaten down, shift the sheep over to the other side.

Pasturing with Other Species. Because of the specialized shape of their teeth, sheep do eat grass down closer to the ground than cattle can. However, if they’re not too crowded, cattle and sheep have been known to share a family pasture successfully. On the other hand, cows—and hogs, too—are much larger than sheep, and there have been cases when a pregnant ewe running with them got injured.

Other species pasturing with sheep have been used in the role of protectors. A donkey in with sheep is quite likely to turn the tables on predator dogs and chase them. Some goats will also stand up to dogs.

Water and Salt: Sheep need a reliable supply of clean water and a source of salt. You can buy the salt as a 50-lb. block at the livestock feed store.

Winter Feeding: As with all grass-eating livestock, the longer winters are in your locale, the more expense you’ll have providing feed, and the more labor you’ll have feeding it, and cleaning out the barn come spring. Some good winter feeds are almost free. Sheep enjoy being allowed to glean in harvested corn fields. The old-timers also fed them root crops from the garden in winter to supplement their hay. Some grain is traditionally fed at least in the period before and after lambing. Hay will be the bulk of their winter feed: 2–4 lb. of legume hay per day per sheep. On a basic hay and grain diet, each sheep will need about 10 bales of hay and about 75 lb. of grain to get through the winter.

Summer Supplements: To get good wool and normal growth, sheep have to eat. So hay and/or grain are used in summer to supplement if their pasture is poor: anywhere from ¼ to ½ lb. of grain per animal per day.

Housing and Fencing

Housing: Consider what your climate is and what the climatic origin of your particular sheep breed is. If you are raising only a couple of weaned lambs for meat to make use of your grass crop, you don’t need to provide more than shade from the sun—either trees or a shed. Sheep have warm fur coats and don’t mind rain a bit. If you are wintering over pregnant ewes, you do need some shelter for them in very cold weather (when temperatures fall below freezing), and at lambing time, and right after they are sheared if the weather turns cold. Other times they can live out in the open. Just about any old building will do, even a 3-sided one—except for during lambing, when pens are also necessary. You can even lamb on pasture (“Spring Pasture Lambing” audio, by Janet McNally; 800-748-9808). A creep (a feeder designed to allow young sheep but not adults to get the food) is advisable.

Don Fallick, my fence and barn expert, agrees: “Unless you live in a polar region, sheep don’t really need a barn. A loafing shed to keep off the sun in the summer and protect from wind the rest of the year works fine. Some folks like to bring their sheep into a pen in a great barn during lambing time. With the advent of electric sheep clippers, it has also become common to see sheep brought to the barn for shearing.”

Hay Rack and Grain Trough: It makes your hay go farther if you provide a hay rack in which to feed it—and the same applies to a feeder trough for the grain. A trough is easy to make by just nailing boards together in a rectangular shape.

Manure: When you have confined sheep you have sheep manure. I hear it’s excellent for lawn or garden because it “does not burn” and can be scattered right onto field, gar-
den, or lawn without harm. Or it can go directly to your compost pile and from there wherever it's wanted.

**Of Predators, Problems, and Fencing:** Of all the big domestic animals, sheep are most vulnerable to catastrophe. They have no natural defense against predators, not much good sense about things in general, and a frequently disastrous instinct to follow the leader, no matter what. That means if you have 1 sheep in trouble, you likely have more than 1 in trouble. One sheep grower told me, "I've lost over 100 head of lambs to coyotes in the last 8 years." I asked, "How big a herd was that out of?" I was hoping he'd say something like "thousands." His reply, however, was, "That was from about 60 head of ewes."

Sherrie Campos wrote me: "A pack of dogs ran through our back pasture and Sunday morning we found a literal blood bath in our pond. Our mama sheep, Abby, and her 4-month-old lamb were standing in the pond. We had to go in and pull them out. In horror we found huge chunks of flesh missing and her bare bones exposed, gashes all over her neck and back. Abby died in our arms. Her little lamb almost died. Thor, our precious bottle baby was dead with no mark on him. The vet said he was scared to death. We had 2 funerals that Sunday and another just 2 days later. The children had horrible nightmares for months."

Your well-built fence stands between these lovable innocents and all the bad things out there that could happen to them. Sheep need fencing to keep them out of gardens—and to keep predators away from them, especially bears, coyotes, wolves, and wild or uncontrolled dogs. Even when dogs don't mean to kill a sheep they can; if they run it for the fun of it, the sheep dies of exhaustion. Sheep and goats require similar fencing. If you have to build a fence, that will probably be your biggest start-up expense with sheep. Check the fence line occasionally. Sheep will find and enlarge small holes; and if 1 leaves, being groupies, they all will. The most predator-proof fence for them would be 6-feet-high woven wire with a single tight strand of barbed wire at its base and above its top.

**Herd Dogs.** Sheep owners may be interested in 2 very different types of sheep dogs. One type is the sheep-herding breeds. These dogs literally "drive" or chase the sheep to put a flock, large or small, where it needs to go. Sheep don't have high IQs. Sheep-herding dogs do. I've read that Border Collies are the most intelligent of all dog breeds. I've owned and loved them for years. They helped me raise my children and saved a little kid's life more times than I like to remember. Mike and I lived on a ranch that was afflicted with coyotes, wolves, and wild or uncontrolled dogs. Even when dogs don't mean to kill a sheep they can; if they run it for the fun of it, the sheep dies of exhaustion. Sheep and goats require similar fencing. If you have to build a fence, that will probably be your biggest start-up expense with sheep. Check the fence line occasionally. Sheep will find and enlarge small holes; and if 1 leaves, being groupies, they all will. The most predator-proof fence for them would be 6-feet-high woven wire with a single tight strand of barbed wire at its base and above its top.

**Guard Dogs.** The other type of sheepdog breed is the guard dog. A good guard dog does not chase or kill sheep. It remains with the herd day and night, following it everywhere, living in the field with it rather than in the house with you. Unsupervised, they will protect the flock from predators, from coyotes, wild dogs, wolves, etc. The typical guard dog is big, about 100 lb., placid and aloof in temperament, able to live and work alone at their post. They typically respond only slowly to human command, but in a battle they move quickly to accomplish their job. Guard dog breeds are Anatolian Shepherds, Great Pyrenees, Maremmas, Komondors, Kuvasz, and Shar Planinetz. The Great Pyrenees dog is the size, shape, color, and texture of a sheep. I kid you not. And the idea is that they live with the sheep, but act like a dog protecting its family if a predator comes around. The guard dog is effective because it's big and it barks. It defends against other dogs because the larger guard dog easily establishes dominance over a possible predator dog, and the predator gets distracted in dog interactions rather than chasing sheep. Guard dogs also will threaten, even attack sheep predators, although they do not pursue a predator if it leaves, remaining instead with the herd. The best guard dogs are mature rather than young and playful. Not every member of a guard-dog breed makes the best guard dog. One traditional way of raising the best of these is to have a puppy of the breed be adopted by and nurse from a ewe. For more info, look up "livestock guarding dog" or "working dogs" on the Internet. The Maryland Small Ruminant web page has many articles on predator behavior (coyote, wolf, bear . . .), identification ("Something's been killing my sheep, but what?") and defenses (fences, management, guard animals): www.sheepandgoat.com. "Using Guard Animals to Protect Livestock" is at www.conservation.state.mo.us/documents/landown/wild/guard_animals.pdf. The book . . . May Safely Graze: Protecting Livestock Against Predators, by Eugene Fytche, has chapters on various guard animals.

Anyway, if you're serious about sheep, you may well want to get serious about a sheepdog too. Our shepherders couldn't have made it without the dogs who would move the herd at the proper signal from the herder. Or try a guard llama. My friend Janice Willard says coyote predation on her flock stopped after she acquired an adult male, not-castrated llama to stay with them.

**Reproduction**

**The Ewes**

**Fat Ewes.** Overweight ewes are difficult to get pregnant. So if your ewes are too plump, they should be dieting starting at least 6 weeks ahead of the expected breeding date. Obese ewes are also at risk for pregnancy toxemia. In that case the heavily pregnant ewe acts listless, walks aimlessly. Her muscles twitch. She grinds her teeth. Then comes a coma followed by death. Obese ewes that are pregnant with twins or triplets and who have been underfed in late pregnancy are most likely to develop this (also called "twin-lambing disease" or "lambing paralysis" or "Ketosis"). There's no cure, only prevention—the diet before getting pregnant. Then take them off the diet and flush them in the usual way.

**Flushing the Ewes.** This is done about 2 weeks to 10 days before breeding, when the sheep is ovulating the eggs that will be fertilized by the ram when she is bred. The idea is to persuade her body to make as many eggs as possible, because twins and triplets are extra profit for the grower. And most growers figure that just barely to make it at least half the ewes must have twins—a "150 percent lamb crop." So the ewes are "flushed" by putting them out on the lushest pasture, or feeding the best legume (alfalfa) hay—as much
as they will eat, or by adding a grain ration, or increasing the
grain ration by about a half more. Ewes flushed this way
do “shed” more eggs and thus have more multiple births.

Breeding-Time: Eye, Tag, and Foot-Check. If the breed is
not open-faced owners may “eye” the sheep, which means
clipping wool away from the eyes. At the same time,
they typically prepare for the breeding by cutting wool from
around their animal’s vaginal opening. That’s called “tag­
ging” or, at more length, “clipping wool from around the
dock.” The argument for doing it is that it keeps the animal
cleaner and prevents wool from getting in the ram’s way
when he’s trying to connect. And while the owner is at it,
the sheep’s feet get checked and trimmed as needed. Sheep
hooves are trimmed the same as goat hooves. Use a sharp
knife, pruning shears, or hoof trimmers from a livestock
supply store.

Breeding Season. Except for a few breeds, most sheep
have a natural mating season that extends from early Sep­
tember through December. During that breeding season
your ewes will go into their sexually receptive, fertile “heat”
phase lasting from 3 hours to 3 days on a cycle of about
every 13–19 days, 17 on the average.

Because the gestation time is 5 months (143–151 days
to be precise), a ewe bred in September will lamb in chilly
February. A ewe bred in December will lamb in balmy May,
which reduces the risk of a chilled lamb. On the other
hand, lambs born in February will be husky enough to go
out in the weather and eat grass as soon as it’s coming on
well, and thus be able to take advantage of the entire grass
season for their growth. And they’ll be ready for market
sooner than May lambs. So either way has advantages.

Some growers just leave the ram in with the ewes and let
him service them whenever. In that case the ram decides—
and he will probably breed them early rather than later.

Then your lambs will arrive in January, or possibly February.

Age of Ewe at Breeding. A ewe that is at least 9 months
old can be bred. She is a little more likely to require assist­
ance during lambing, but statistical studies have shown no
likely damage to her body, and by breeding her that first
season, she’ll produce 1 extra annual lamb crop over her
reproductive lifetime.

The Ram: Most sheep farmers who have a half dozen
ewes or more keep a ram, or else they use artificial inse­
nation. A mature ram can impregnate or “service” as many
as 30 ewes. A ram that was born just the previous spring
can also service ewes, but not as many—maybe a dozen.
However, if you have a small flock, a yearling ram can be a
good way to accomplish your breeding. You can buy a year­
ling ram from off your farm to avoid in-breeding. After he
has bred your ewes, you might eat or sell him. That way
you don’t have to pay to winter him. If you do decide to
keep a ram, he will be able to continue doing his job for
years, but the number of ewes he can service and the com­
parative fertility of his sperm will start gradually dropping
after around age 5.

People with only a few ewes are more likely to consider
the drawbacks of keeping a ram. A ram tends to be larger,
more grumpy, even dangerous. For example, a Dorset ewe
weighs 125–150 lb., but a Dorset ram will weigh 175–200
lb. Since a ram has to work only a few minutes a year to do
his job, some small flock owners avoid the expense and
bother of owning one by renting a ram when needed, or
taking the ewes to a ram, or by artificially inseminating.

Pregnancy and Lambing

Pregnant Ewes. Make sure that your pregnant ewes are
getting enough nourishing food, especially during the last
half of pregnancy when the fetus is growing fastest—par­
ticularly the yearlings because they are themselves still grow­
ing, too. Good legume hay fed free choice as the grass sup­
dwinds is essential. Growers who feed grain give it to
sheep who are pregnant, lactating, or being prepared for the
show ring or meat market. They gradually increase the grain
ration for pregnant ewes from about ¼ lb. at the beginning
of gestation to ½–1 lb. per day in the last 6 weeks of preg­
nancy. During these last 6 weeks of pregnancy the ewe es­
specially needs generous feeding plus plenty of exercise. This
regimen is thought to help prevent pregnancy toxemia.

Lambing Shelter. Your pregnant ewe will carry her lamb(s)
for about 5 months, and then give birth. It’s important to be
prepared for that lambing event. The most dangerous pe­
riod in a sheep’s life is its first 48 hours. Planning ahead for
good shelter can help minimize problems.

Lambing Pens. Your lambing pens should be in a place
that’s roofed at least enough to where it will be absolutely
dry inside and thoroughly protected from wind. An easy
way to create (and dismantle) pens as needed is to have a
supply ready of what looks like gates without fences (about
8 feet long by 3 feet high), plus some baling type wire.

When you need to create a pen you take 2 “gates,” arrange
them in an “L” shape against a corner pair of walls, and wire
them into place. That gives you an instant square-shaped
pen. Or you can arrange them against a flat wall and have a
3-sided pen. Make your “gates” ahead of time and use them
year after year. Once you have them made, you’ll probably
discover some other good uses for them too.

Lambing. Because the lambs are typically born during cold
weather, and because birthing is always a critical time for
mothers and offspring, you need to be close by. I remember
my daddy and the sheepherder making the rounds at night
with a Coleman lantern and a big quart jar of iodine to dab
on the babies’ cord ends. When sheep have babies they
tend to have them all at once. A flock of a thousand will all
lamb out within 3 days or so, and it is bound to be a sleep­
less, exhausting time for the shepherd because he or she has
to check the ewes every 2 hours, day and night, to give help
where it’s needed. Even when you own only a few ewes
rather than hundreds, they will still lamb near the same
time and need to be checked on that frequent schedule day
and night until the birthing is accomplished and the lambs
are on their feet, nursing, dry and obviously thriving.

Lambing Checklist

1. Birthing hang-ups: Sheep and goats are born the same
way, so these instructions will work for either one. If
the fetus is normally positioned you’ll see the front feet
and nose first. Usually the ewe doesn’t need help, but
once in a while you’ll notice an overly long labor that
isn’t producing anything yet. In that case, wash your
hands—and arms—well with a disinfectant soap and
feel up her vagina. The fetus can get lodged in her
birth canal sideways, or it may be coming out back­
wards, or a leg may be out of normal position and
somehow preventing the normal delivery. You gently
feel around and try to figure out what the problem is,
and then figure out how to fix it.
2. Cord: After the lamb is born, pinch or cut off its umbilical cord 4–5 inches from its belly. Then dip its navel cord into an iodine solution or paint it with the iodine. That prevents infection.

3. Warmth: Have old towels, blankets, burlap bags, warm rags, or some such available in case you need to wrap a chilly lamb. Some growers even supply a heat lamp for drying off and warming newborn lambs right in the lambing shed. Chilling is the problem you’re most likely to have. This is a big reason why at lambing time you check your sheep at least every 2 hours. If a lamb gets chilled, it can be quickly fatal. If you find a chilled lamb, even one that seems nearly dead, wrap it, get it into the house, warm it up, and then get it dry. For the worst cases, put the lamb into hot water for a few minutes—all but its head. Then dry it, wrap it in something, and put it in a thoroughly warm place such as a box by your wood stove, or under a heat lamp. A lamb in severe chilling crisis can also be helped by giving it warm milk to drink. Warm it thus for a few hours. Then it should be able to return to its mother. If the lamb has recovered from its birthing chill, has a mother that lets it cuddle up to get warm, and nurses regularly, it can endure temperatures that are even below zero—if you have it and its mother in a pen that is at least dry and sheltered from the wind.

4. Has the newborn lamb nursed on its own from the mother within half an hour of its birth? If not, move it gently close to the ewe’s udder. Take one of the ewe’s nipples in your hand, gently open and hold open the lamb’s mouth with your other hand, and squirt her milk right into its mouth. This first milk is the antibody-containing colostrum, and the lamb needs it to thrive.

5. Did a ewe have twins or triplets? Is one of them visibly weaker than the other? If so, make sure that the mother is noticing both of them and nursing both of them, because it is possible she may not attend to the weaker one or may even harm it.

6. Overcoming lamb rejection: If you had to take the lamb away to warm it or if the ewe hasn’t clicked into her motherly instinct with it yet, take some of her placenta and rub it across the lamb’s body, especially right about the anus. That’s the place a mother smells in order to identify her baby. After smelling her placenta on it, she should be satisfied and cooperate in letting it nurse or letting you help it nurse. That system can work to get a ewe to adopt an orphaned lamb. Or adoption can be accomplished by skinning the dead lamb and then draping that skin over the orphan.

7. Pinning: A lamb’s first feces tend to be sticky. Sometimes the tail gets literally glued to its body and it can’t get out any more bowel movements. This will soon be fatal if not fixed. You just get it loose, clean up the lamb’s rear, and give it a fresh start. (Most owners will cut off those tails a week after birth.)

8. Mastitis: Avoid this inflammation of the udder by not overfeeding the ewe. Ewes with access to good grass will do fine without any grain. Ewes being fed grain shouldn’t get more than what they were eating before the lambing, as more would cause them to make more milk than their lambs can drink and the backup of milk can cause infection.

9. Does the ewe lack milk? This is rare, but it can happen. In that case you have a bum lamb and need to get it started on the bottle. But don’t give up too soon.

**Bum Lambs:** A bottle-fed lamb is known as a “bum lamb” or a “bummer” or a “cosset.” It’s perilously easy to turn a lamb into a bum lamb. To avoid this, just coax or force the sheep’s nipple into its mouth. Reflex will do the rest. If you feed it its first meal from a bottle instead of managing to get ewe and lamb connected for the purpose, from that moment on it’s going to look at you and follow you as if you were its mother—and bleat for you when it’s hungry.

**Bottle.** Any glass bottle with a narrow neck can be a lamb bottle if you have a rubber nipple to pull over the neck of it. (Hold the bottle firmly by the neck to keep the lamb from jerking the nipple off with its forceful sucking and spilling the milk.) Or you can buy lamb feeding bottles from a livestock store—maybe even your local pet store.

**Schedule.** The lamb will do best if it is bottle-fed every 4–6 hours until it is 3 weeks old, and then every 8 hours or so for the next 2 months. At the beginning don’t try to get the very young lamb to drink more than 2 oz. at each feeding. Its appetite will gradually build up.

**Milk.** You can feed a bum lamb spare goat or cow’s milk once it’s started, but it’s important—if you possibly can—to get the mother’s colostrum milk into it for its first few days. That may mean milking her by hand and then putting the milk into a lamb bottle for feeding. When the old-timers couldn’t get the colostrum milk into a bum lamb, they would substitute a pint of cow or goat milk with an egg beaten up in it and a pour of dark corn syrup. Livestock stores can get you “lamb milk replacer,” which is better food for them in terms of composition than goat or cow milk, but not cheap. But there’s no substitute for the antibodies in natural colostrum.

**Weaning.** Lambs start out completely on mother’s milk. By around 2 months old, or whenever the grass is sufficiently up, they’ll start eating grass in addition to nursing. Gradually they shift to independent eating completely. Creep feeding is the practice of providing grain to the lambs in special feeders that the adult sheep cannot squeeze into. Creep feeding will cause lambs to gain weight faster than they would otherwise.

**Lamb Marketing:** Lambs can be sold to 4-H members to use as fair projects, or kept to raise for family meat, or
marketed as spring lamb to ethnic groups that have traditional lamb feasts for Passover or Easter. This market is generally located in big cities and wants a lamb under age 5 months. With the right contacts, it can pay off. Try not to make pets of lambs that will be eaten.

Sheep Vetting

TAIL Docking: Something most city folks don’t know about sheep is that their tails are generally cut off when they are young—by the knife or by putting a very tight rubber band around its base to cut off the blood supply to it. The arguments for docking (cutting off) the tail are: If you don’t dock the tail, fat accumulates in there and it gets pretty big. It also tends to get dirty with a collection of manure, burrs, and so on—especially if the sheep get the runs from a binge of too much grain or being suddenly put out on lush pasture. A build-up of manure under a tail can get maggots and be a big problem—especially in a rainy, chilly climate. And some growers believe that a tailless ewe is easier for a ram to breed successfully.

The arguments against docking are that if you feed your animals carefully and avoid diarrhea episodes and plan to market or butcher them privately before breeding, there’s really no need. A further argument is that long-tailed ewes actually breed fine, too. A final argument is that it’s much ado about nothing because there are Mediterranean communities where a fat-tailed sheep is normal, and the big tail is a valuable product of butchering.

The more I know, the more I know I don’t know. But as a personal preference, I favor the docking. There are several good ways to accomplish it if docking is your choice:

Elastration. The rubber band is a special type that is put on using a special tool called an “elastrator.” The banded tail soon drops off by itself.

Cutting. To cut a tail off, first tie a tough twine very tightly around the tail’s base. That cuts off the blood flow like a tourniquet. Choose a cutter that is strong, but not too sharp. (Sharper cutting edges actually make for worse bleeding.) Heat your cutter blades. That’s for sterilization and because the hot blades cauterize the wound. Catch the lamb, hold it tightly between your legs with its hind end to bleeding.) Heat your cutter blades. That’s for sterilization and because the hot blades cauterize the wound. Catch the lamb, hold it tightly between your legs with its hind end toward you. Holding it between your legs frees up your hands. Then simply cut off the tail with your nippers. Cut the tail off 1–2 inches from its base. If you cut shorter, it will bleed worse. Smear on wound-coagulant (“blood stop”) and an antiseptic such as iodine. In an hour smear on wound-coagulant and antiseptic again. Done this way you’ll discover that an hour later your lamb seems just as happy and healthy as if nothing had happened to it. Twenty-four hours later, take off the tourniquet twine and put on a final application of the coagulant.

Castrating: The old-timers believed that the meat of full males wasn’t as good. That’s true if you’re going to wait over a year to eat it, but any male lamb that was born in the early spring and killed in the late fall will taste just as happy and healthy as if nothing had happened to it. Twenty-four hours later, take off the tourniquet twine and put on a final application of the coagulant.

Parasites and Diseases: Prevention is always the best approach. Buy from a healthy flock, give good feed, keep their shelter clean, rotate their pasture. Nevertheless, problems do happen. You can buy medicines for common health problems from your vet, or at your livestock feed store, or through a mail-order livestock-products supplier.

Worms. Having worms is the most common health problem that sheep may get. It’s best if you can keep a worm problem from starting. The worms are picked up by the sheep from grazing on an infected pasture. Pasture rotation helps to keep them from grazing too close. If your animals do get worms, then you can give them a commercial wormer.

Foot Rot. Foot rot is fairly common, so if your sheep limps, the cause is quite possibly foot rot. It is treated by first trimming bad areas away from the hoof, then applying a medicine to the hoof. Prevent it by avoiding overcrowding among your flock and keeping their hooves trimmed neatly. A popular medical preventive is to drive your sheep through a footbath that has copper sulfate or formalin in it. The traditional dimensions for such a footbath trough are 1 foot by 6 inches by 16 feet long. Place portable fence sections on either side of the trough (tilted enough outward that the sheep can get through). Or you can paint the copper sulfate on their hooves with a big brush. In areas where sheep are common and sheep services are available, you may be able to get on the route of an itinerant sheep-dipper who will furnish the medicine, the vat, and the effort to run your sheep through it—for a fee.

Wool: Shearing to Spinning

Why Shear? Do shear your sheep, even if you don’t use or sell the wool and must throw it away. If you don’t shear, the sheep shed some of it anyway and, unless you live extraordinarily far north or at high altitudes, are miserably hot wearing the rest through the summer.

When? There is no absolute written-in-stone time you have to shear. It’s a judgment call. Most sheep owners shear in the early spring. Or in the fall and spring. Most growers believe that if you don’t shear them before the weather gets hot the sheep may feel hot or, worse, get worms or be sick. Growers generally wait for spring shearing until just before the sheep go off hay and onto grass pasture. One reason for that timing is that the new grass tends to have a laxative effect on the sheep, and that, of course, dries the wool around their rear. Some old-timers also claim that warmer weather increases the amount of grease in the fleece, which makes cutting easier and the fleece heavier (it sells by the
Also, in very humid weather, the wool would be wet. It's pound). Unless you have shelter for the sheep and have them in it, and if you live in a harsh climate, it's wise to wait until the warmer weather has arrived to shear because sheep have delicate health, and a night out in a storm immediately after shearing can take an awful toll. That one's from sad experience.

But a few growers shear only in the late fall just before the sheep are moved into winter housing from their pasture. If that housing is good shelter, the advantage of winter shearing is cleaner wool (outdoor living is cleaner) and a better wool market since you're selling in the off-season. Market lambs that will be butchered in the late fall can be sheared at about 5 months of age—or as part of a general fall shearing.

Who Will Shear?
Sheep-shearing isn't easy for an amateur. The goal is to get off the entire fleece in 1 piece, leaving the sheep looking neat—and do it with 1 swipe of the clippers in each place so that the shorn wool is of a maximum, and uniform, length. If you have to take more than 1 swipe to get the wool off your sheep, there will be wool of uneven lengths (called "second cuts"), and that diminishes the spinability of the wool. You need somebody to do it for you, or show you how, if you've never shorn before. There are shearsers who work for hire, going from farm to farm, and people with small flocks who do their own shearing and will also shear for hire. Your basic choice is to hire or learn how.

HIRE A PROFESSIONAL: So ask around of other sheep owners to find such a person. Many sheep shearers have a regular schedule during shearing season. The shearer may require a minimum number of sheep, or a minimum fee. In that case, you might be able to get permission to take your sheep to a place where the shearer is scheduled to visit and have them done there. But hiring a professional is possible only in areas that they regularly visit during shearing season. If you live in an isolated region, or are watching your budget closely, or simply want the adventure of learning this skill for yourself... read on.

DO IT YOURSELF: Shearing a sheep is challenging for an amateur, but anybody can learn how. It helps to watch somebody else do it first, although plenty of people have learned to do it without even that much help. You can order a 2-hr instructional video, "Shearing Techniques," from Rural Route Videos: 800-822-7703; PO Box 359C, Austin, Manitoba ROH 0C0, CANADA; martin@ruralroutevideos.com; www.ruralroutevideos.com. (They also offer videos on "Starting Your Border Collie on Cattle, Sheep or Ducks," "The Basics of Good Sheep Management," "Working Horses of the '90s," "Old-Time Farming," and "British Sheep Fairs." Price per video: $29.95 + $5 s/h.) Don't expect your sheep to look very great the first time. The important thing is just to give it that haircut, to get the essential accomplished somehow. You'll get better at it and more comfortable with doing it every time.

How to Shear
1. CHOOSE A SHEARING DATE: See "When?" above. Also, in very humid weather, the wool would be wet. It's best to shear after a spell of dry weather.

2. OBTAIN A CLIPPER: Hand clippers are cheap and can be made to do the job, as long as you don't have a large number of sheep. You could make do with garden-type shears. Have your shears really sharp. Electric clippers are expensive, but you have to buy them only once, and they're much easier to do a good job with. You can buy straight-bladed manual 6-inch sheep shears.

3. CHOOSE A SHEARING PLACE: Do your shearing in a small pen so that, if your animal does get away from you, you don't have to chase it all over creation to finish.

4. PREPARE A SHEARING SURFACE: Spread a tarp or plastic sheet on the ground, or shear on a clean floor well away from anything like straw or dirt that could get into the fleece. You want to keep the wool as clean as possible.

5. GET SHEEP: Herd or wrestle the sheep into the pen and onto your clean surface.

6. POSITION SHEEP: Have somebody else there with you to help hold the sheep. Keep in mind any time you handle sheep that you should not grab wool. Wool grabs can hurt your sheep—or mess up the natural appearance of the fleece. Get the sheep firmly between your knees on its side or back, with the head pointing toward your behind. Positioning the sheep on its rear minimizes the fight.

7. CULL CLIP: First you cut off any wool that holds fecal material, called "dung locks." Also cut off knots of matted wool, called "grease tags." Cull clippings are most likely to be from around the anus—and in the belly area. Owners of small private herds usually sell their wool to hand spinners, and these people want only clean wool. So people shearing for hand spinners are likely to discard the sheep's leg, belly, and head clippings if they are dirty or full of chaff, burrs, seeds, thistles, etc. After being cut off, the cull clips are thrown away.

8. DO THE WOOL CLIP: Now you're doing the serious shearing. Clip away, turning the sheep's body as needed. Clip as near the body as you can. The sheep's wool, if you work right, will come off all in 1 piece that holds together nicely, and that's the "fleece" or "wool clip." You will sort of work your way thus from its head end toward its rear end until you arrive at its bottom—and by then you have all its wool off.

a. Start with the animal's head.
b. If you're using hand shears, clip across its body from one side, across its back, and across the other side. You work your way thus from its head end toward its rear end until you arrive at its bottom—and by then you have all its wool off.
c. If you're using electric clippers, make strokes from head to tail that are as long as possible. Pros can reach from one end clear to the other end of a sheep's body when shearing. In this case, another way to do it is (again starting with the head end) to first do one whole side (head to tail), then the whole back (head to tail), and then the other side (head to tail)—and then you're done.
d. Clip as close to the sheep's body as you can. The basic skill of shearing is learning to clip as near the body as possible, using a single cut only and without cutting the animal's skin. When you are just learning to shear, and if you are doing it with hand shears, aim to hold the cutter about 1/2 inch out from the skin. If you go
closer, you risk having a bleeding sheep. With clippers you can go closer. **Be careful not to nick your sheep's ears or teats!** But cut close, because if you cut the wool in the middle of its length, you get short wool that is not good for spinning.

e. A corollary of the "cut close" rule is: **No second cuts allowed.** That is, no going back and taking more wool where you've already cut once—for if you recclip (trying to get what you missed the first time), you just get loose, short strands that are no good anyway. If you do make a second cut for the sake of the sheep's appearance, just throw the short wool out. It can't be part of the fleece.

9. **TREAT THE NICKS:** Beginners—and old-timers, too!—inevitably make a few nicks, so forgive yourself. Treat each with a disinfectant before you turn the sheep loose again.

10. **CHECK THE HOOVES:** This is the same as the fall prebreeding check-up. Trim as needed.

11. **BAG THE FLEECE:** Have ready a bag such as a gunnysack. Gather up the fleece and put it into the bag.

12. **ON TO THE NEXT:** Turn that sheep out and grab the next.

13. **PACKAGE THE WOOL:** Each fleece should all be clinging together in a single piece. First lay it out and examine it. If you're selling to hand spinners, trim off any remaining dirty wool. For the commercial market, you can leave so-so dirty wool. Factory-handled wool gets a chemical treatment to dissolve dirt, etc. (which is why homespun feels better next to your skin). If the wool is damp or even wet, let it dry before the next step.

   Gather up the fleece with the part that was closest to the sheep's skin now facing outside. Never tie a fleece with plastic twine, for those fibers can get mixed with the wool and create a problem at future processing stages. Paper twine—if you have it—is fine. To keep the fleece at home, store it in a loose state in paper bags or cardboard boxes. Never store it in a plastic bag.

14. **LOOK FOR TICKS:** Now you're done. Go someplace where you can strip naked and have somebody else check you all over for ticks.

**Wool**

**Wool Marketing:** Wool is sold by the pound. Some sheep keepers are into spinning and weaving, and they keep the animals mainly for their personal wool crop, which they'll card, spin, and weave themselves. Many sell to other hand spinners or to a larger wool buyer. In general, hand spinners like wool in interesting colors like black, silver, brown, or blue, and will pay 2–10 times as much as commercial wool buyers, depending on how pretty—and how scarce—the color and texture of the wool is. Ask around to find out where other wool growers in your area are selling. You may find some willing to combine with you to make a commercial-sized shipment. The price of commercial wool depends on what is happening on the international wool market, which fluctuates and cannot be reliably predicted.

**Of Wool and Market Lambs:** These will provide 3–5 lb. of fleece each at a 5-month shearing. After a private butchering, those sheep hides can also be tanned for sale. If the lambs had unusual colors or very nice wool, these tanned hides can be as profitable as the meat. (When sheep are sold for meat to commercial buyers the grower can't get the sheepskin.) Your county extension agent may be able to help in this marketing area.

**Cleaning a Fleece:** A spinner can take a clean fleece and spin it before washing—it's called spinning "in the grease." But some people prefer prewashing. And many fleeces aren't that clean.

**About Lanolin.** Any "raw" wool fleece has a greasy feel from the natural sweat and lanolin wax. The older the wool gets before it is spun, the hotter the wax on it gets, and the harder it will be to spin. Once you have your wool cleaned, it will weigh 30–60 percent less than it did before, because of the weight of the grease removed. But don't try or expect to get out all the grease. Leaving some permits easy spinning and creates a desirable water-resistance in your finished product. Since wool for dyeing must first have all the grease washed out to enable the mordant chemicals to take hold, many spinners seek out naturally colored wools: not just white, but also the shades of brown, black, and gray.

Natural wool with some of its oil left in retains its water-repellent qualities. So don't wash all of the lanolin out of your wool. However, wool that you're planning to dye does have to have almost all the lanolin washed out or the dye won't set. To make homemade lanolin, boil a batch of sheep wool. However, wool that you're planning to dye does have to have almost all the lanolin washed out or the dye won't set. To make homemade lanolin, boil a batch of sheep wool, and drain the oil. The lanolin is the oil. If you handle newly sheared wool you get your hands loaded with lanolin. It's very soothing and healing to the skin.

**Degreased Wool.** If you do remove all the grease in your cleaning process, or if you are working with purchased "scoured" (degreased) wool, you'll need to replace some oil. Sprinkle several drops of olive, mineral, or tanner's neat's-foot oil on your fibers, roll them up, and let them rest at least a quarter-hour before spinning.

**Cautions When Cleaning Wool.** A problem with wool is its tendency to be damaged by harsh treatment. When cleaning it, never agitate it in the water. Never wring or twist it; it is all right to squeeze or press it. Always change
temperatures gradually. Never immerse it in any strongly alkaline solution: no bleach, no “super-cleaners” (use mild soap, mild detergent, or washing soda). Don’t use too much soap. If the water is too hot, the wool will shrink and wad up into little knots and you can’t even card it. Wool isn’t that different fresh from the sheep or in the sweater. Remember you’ve got 100 percent wool! Dry the wool in the shade, not in the sun. Or if you choose to dry in the sun, minimize its exposure to a few hours. Don’t let the wind blow it away.

Wool-Cleaning Steps

1. For this first step, you’ll want to work with the wool over a newspaper outdoors. The fleece is probably dirty and has seeds and the like in it. Pull the strands gently apart and let that kind of thing simply fall out. While you’re doing this you may want also to sort the wool somewhat. Any fleece contains more than 1 quality of wool. The shoulders and upper back tend to have the finest, softest strands.

2. Put wool in a tub or other container with warm water (95°F) and a very mild soap or detergent. Let it soak in warm water 10 minutes, drain, soak again, and drain again.

3. Add your cleaning agent to warm water, and make sure it is thoroughly dissolved before adding wool. Some people gently wash the wool, pulling it apart with their hands. Some just let the wool soak in this mixture another 10 minutes, drain, soak in fresh cleaning agent water again, and drain again.

4. Rinse twice using the same procedure as in step 2.

5. Dry by spreading the wool on paper or by hanging it in the shade.

6. At this stage you dye the wool, if you want to. Some dyes don’t require a mordant (a dye fixative). All the lanolin must have been washed out if you use a mordant. You can mordant the wool before, during, or after dyeing. For further information on wool dying, see Growing Herbs and Plants for Dyeing (1982), and other books and magazine articles probably available in your local library.

7. An optional further cleaning and preparation step is working with the wool using cards.

Wool Carding: Wool cards are rectangular pieces of thin board with a simple handle on the back, or at the side. To this board is fastened a smaller rectangle of strong leather, set thick with slightly bent wire teeth, like a coarse brush or currycomb. In the early days, the leather back of the wool card was pierced with an awl by hand, the wire teeth cut off from a length of wire, slightly bent, and set one by one. The carder takes 1 card with her left hand and, resting it on her knees, draws a tuft of wool across it several times until a sufficient quantity of fiber has been caught upon the wire teeth. She then draws the second wool card across the first several times until the fibers are brushed parallel. Then by a motion, the wool is rolled or “carded” into small fleecy rolls, which are ready for spinning or to fill quilts.

Making a Wool Quilt: Start with a layer of cheesecloth. Put the wool on the cheesecloth. It should be a ½-inch thick for a regular quilt, but for a thick comforter the wool layer can be 1, 2, or even 3 inches thick—or as thick as you wish. Put a layer of cheesecloth on top and coarsely stitch it into place with a pattern of diamonds or squares. This prevents the wool from shifting to the corner. The prepared layer can then be covered with cotton, sateen, outing flannel, satin, or whatever is desired. It can be tied with yarn or baby ribbon or coarsely stitched. The cover should be removable because you want to avoid washing the wool very much. I guarantee, if you keep the cover clean, the wool inside the cheesecloth won’t get dirty in 25 years and will stay fluffy, light, and warm.

Felting: This fairly simple craft turns wool into wonderful hats, boots, rugs, clothing, etc. Check out Felting by Inge Evers; Felt Craft and Felting by Hand by Sue Freeman; The Felting Book from Louet Sales, PO Box 267, Ogdensburg, NY 13669; 613-925-4502; fax 613-925-1405; info@ louet.com; www.louet.com; and Felting by Beverly Gordon.

Note: For tanning and dyeing information, see Chapter 8.

Spinning and Weaving: “Spinning” means making yarn, cord, or rope by twisting small pieces of fiber (cotton, straw, wool, hemp, etc.) around each other enough so that they then stay together; by spinning you create a far longer, stronger fiber than what you started with. It takes only a few hours, or less, to learn to spin, though the yarn produced by a beginner may have some imperfections. It’s easiest to start learning on a hand spindle and only then shift to using a spinning wheel (which tends, at first, to whip the yarn out of the apprentice’s hands disconcertingly fast). Incidentally, a sheep that was in very poor health at some time during the year may give wool that can be broken and thus won’t spin well.

A spinner is concerned with basically a 3-step process: drawing out fibers to be spun, twisting those fibers together, and arranging the already-twisted fibers. A wheel supplies the twist and may also arrange the spun yarn. I’m not going to tell you more than this of spinning or weaving because, first, I’m not personally knowledgeable; second, on this subject there is a wealth of information in your library already; and finally, this is very much a living craft, with groups of dedicated spinners and weavers to be found in almost any community.

Weaving is the next step, wherein you set up threads on a loom and weave them into cloth.

You’ll learn fastest and easiest from friends rather than out of books. To locate such friends, ask at your local “needle nook,” or look in your yellow pages directory under “spinning,” “weaving,” or “crafts” for leads, or visit your county fair home economics exhibit, find the handmade fabrics section, and sleuth out names and addresses to contact from there.
Suppliers in U.S.

Alden Amos wrote the Spinning Wheel Primer and The Book of Spinning. He makes custom spinning wheels and sells supplies: 209-223-3602; 1178 Upper Preveliti Rd., Jackson, CA 95642.

Green Mountain Spinnery: 800-321-9665; 802-387-4528; PO Box 568, Putney, VT 05346; spinnery@yarn.com; www.spinnery.com.

Harrissville Designs charges $10 for their catalog, credited if you order: 800-338-9415; Box 806, Harrissville, NH 03450.

Louet Co.: Contact the U.S. at 613-925-4502; fax 802-387-4841; 808 Commerce Park Dr., Ogdensburg, NY 13669. Their Canadian address is 3425 Hands Rd., Prescott, Ontario K0E 1T0, CANADA; info@louet.com; www.louet.com.

(The) Unicorn is the U.S.’s largest mail-order distributor of books on basketry, beadwork, crochet, dyeing, knitting, needlepoint, tatting, weaving, spinning, etc.: 800-289-9276; 1338 Ross St., Petaluma, CA 94954. Their 11 x 17 in., 75-pg Unicorn Textile Book Catalog is $3 and worth it.

Vermont Dept. of Agriculture lists fleeces, tools, patterns, etc., direct from Vermont homestead producers, online in the “Vermont Fiber Producers Directory” at www.vermontfiberworks.org.

Webs: America’s Yarn Store offers a $2 weaving/spinning/knitting catalog. Contact: PO Box 147, Northampton, MA 01061-0147; 413-584-2225; fax 413-584-1603; webs@yarn.com; www.yarn.com.

Woodland Woolworks: Free catalogs: “Knitology” and “Spinology.” Good prices on spinning wheels, books, etc. PO Box 850, Carlton, OR 97111; 800-547-3725; info@woolworks.com.

Yarn Barn sells supplies for weaving, spinning (spinning wheels, looms, books, etc.): 800-468-0035; 930 Massachusetts, Lawrence, KS 66044; yarnbarn@grapevine.net; www.yarnbarn-ks.com.

Suppliers Outside of U.S.

Ashford Wheels and Looms offers a full range of fibercraft equipment. There will be an Ashford dealer near you. Their factory/showroom is at 415 West St., PO Box 474, Ashburton, NEW ZEALAND; phone 64-3-308-9087; fax 64-3-308-8664; sales@ashford.co.nz; www.ashford.co.nz. "Send for our FREE Wheel & Loom magazine." They also offer instructional books and videos.

Louet Sales Co.: 3425 Hands Rd., Prescott, Ontario K0E 1T0, CANADA; info@louet.com; www.louet.com.

Pat Green Carders manufactures quality drum carders and wool pickers. "Sales are primarily to the U.S. The price list is in U.S. dollars with no tax, duty, or shipping charge. Free brochure." 604-858-6020; 877-898-2273; 48793 Chiliwack Lake Rd., Chiliwack, BC, V4Z 1A6, CANADA.

Treenway Crafts sells spinning fibers and weaving, knitting and stitching yarns, especially silk! 250-653-2345; fax 250-653-2347; 888-383-7455; 501 Musgrave Rd, Salt Spring Island, BC V8K 1V5, CANADA; silk@treenwaysilk.com; www.treenwaysilk.com.

More Fiber Info

Books: Interweave Press also offers a free, fascinating spinning/weaving book catalog, including Spinning Wheel Primer, by Alden Amos; Hands-On Spinning and Linen: Hand Spinning and Weaving, by Patricia Baines. Paula Simmons wrote Turning Wool into a Cottage Industry (1991) for home spinners who also raise sheep; and Handsemaker’s Guide to Selling, Spinning and Weaving with Wool, etc. For spinning info, read Fleece in Your Hands, by Beverley Horne; The Art and Technique of Handspinning, by Allen Fannin; and Hands-On Weaving, by Lee Raven. For weaving info, see Hands-On Weaving, by Barbara Liebler, The Key to Weaving, by Mary Black; and The Weaver’s Book, by Harriet Tidball.

Sheep Butchering

Because age makes such a difference in the taste and texture of sheep meat, there are different names for different ages. Carcasses are called “lamb” if the sheep was 14 months old or younger at butchering time. In general thinking, sheep could become meat any time after 3 months. They’re considered ideal when they reach 50–70 lb. A 50-lb. lamb will dress out to about 30 lb. meat. Most growers aim for some tree or post in a place that you’ve prepared for the bleeding still young—and not excessively fat. The meat is called “mutton” if the animal was over 2 years when butchered.

Killing a Sheep

The following information is from me and from a USDA pamphlet called “Lamb: Slaughtering, Cutting, Preserving, and Cooking on the Farm”: The animal should be tied to a tree or post in a place that you’ve prepared for the bleeding by laying down straw, leaves, or some such to protect the pelt. Stun the sheep with a bullet (.22 caliber rifle or pistol or larger) in the forehead, midway between and slightly above the eyes. Make the first shot right. As quickly as the animal goes down, bleeding should be begun. You do that with a straight boning knife. Hold the animal down with a knee on or behind the shoulder. With a hand on the sheep’s...
lower and twist the toes off. Don't remove them until the skinning directions tell you to.

and old sheep, it will be necessary to cut across the pastern snap easily and the foot can be removed. On older lambs

should start the day it is removed.

See the tanning section in Chapter 8.

THE PELT: In either case, make certain to cut toward the skin to avoid cutting through the thin membrane, the "fell" covering the outside of the carcass. If this membrane is broken, the lean muscles will bulge through and give the carcass an unattractive appearance. (It wouldn't really hurt the meat any though.) If the fell is broken, try to work around the break to get a new start. After the sheep has been cut up, remove the fell membrane from each sirloin, loin, and rib chop before cooking; the fell becomes hard in frying. When the chop is still cold, the fell peels off easily. Start peeling at the lower end of the chop. Leave the fell on the leg and shoulder roasts while they are cooking, to lessen the evaporation of meat juices. Clean fell on roasts, chops, or stews will not affect flavor.

"FISTING": This is done by pushing the fist under the pelt with the knuckles next to the carcass and the thumb over the first finger. Press the fist up against the skin, working it away from the carcass. Work slowly and avoid tearing through the fell and muscles. Fisting the pelt off is much easier if your hands are kept slightly wet.

THE PELT: For care of the sheep's pelt after it has been skinned off, see the tanning section in Chapter 8. This care should start the day it is removed.

CUTTING OFF THE FRONT FEET: They can be removed by cutting through the joint at the knee or by breaking them at the "break" or "spool" joints. To break the legs there, cut across the tendon between the knee and foot. Grasp the foot in one hand, the leg in the other, and break back and sideways. On young lambs the "break" joint will snap easily and the foot can be removed. On older lambs and old sheep, it will be necessary to cut across the pastern joint and twist the toes off. Don't remove them until the skinning directions tell you to.

HORIZONTAL METHOD: When the bleeding is finished, move the sheep to a clean working area, perhaps on top of a sheet of scrubbed plywood, concrete, or a clean floor. Standing to the side of the sheep, hold 1 front leg between your knees and allow the animal to lean away. Remove a narrow strip of skin down the front of the foreleg, being sure to remove the skin over the knee. Turn the knife (with the cutting edge toward the skin) and make an opening to the neck in front of the breast.

Skin the opposite leg the same way, meeting the cut made in front of the breast. Open the pelt down the neck to the opening made by sticking for the purpose of bleeding it. This will form a V-shaped strip of pelt over the breast. Remove the pelt over the breast by pulling the pelt up and back. Once started, it is best to complete by fisting. After the pelt is loosened over the brisquet (breast/chest), stop and skin out the rear legs.

To do the rear legs, stretch one out and remove a strip of skin down the back of the leg and over the hock (the "ankle" close over the hoof, which bends backward). With the leg still between your knees, turn the knife outward and open the skin from the hock to a point in front of the anus. Skin around the hock and "down" the leg. Remove the foot at the last joint, the one next to the hoof. Follow the same procedure on the other leg. Then fist the pelt off the inside of the legs and over the crotch. From the breast, fist down the belly and around the navel to the opening at the crotch. The carcass is now ready to be hung for evisceration.

SUSPENDED SKINNING METHOD: Tie a heavy string around one of the rear legs and suspend the carcass by that leg from a sturdy tree branch 8–10 feet from the ground or a strong barn beam equally high or some such. On the free leg, remove a strip of skin over the hock and past the dew-claws. Turn the knife outward and open the skin from the hock to a point in front of the anus. Skin around the hock and down the shank. Remove the foot at the last joint. Remove a strip of skin along the suspended leg and cut the skin from the hock toward the anus, connecting with the cut from the other leg. Remove the skin around the shank. Fist along the cut between the legs, removing the pelt around the back of the legs, in the crotch, and around the front of the legs. Suspand the carcass by the opposite leg and remove the foot on the loosened leg. Tie a heavy cord around both rear legs and suspend the carcass now with both hind legs tied.

Remove a strip of skin along the back of the front legs from the knee to the foot. Make a split in the pelt beginning at each knee and connecting at the neck in front of the breast. Open the pelt down the neck to the opening made by cutting the throat for bleeding. Remove the pelt over the breast by pulling the pelt up and back. Once started, it is best to complete by fisting. Fist along the belly and around the flanks, meeting the opening made at the rear legs.

Sides and Back. Open the pelt down the midline of the belly, and loosen the navel. Hold the pelt tight with one hand and fist off the sides. Work around to the back and up around the hind legs. Fist down past the shoulder, around the sides, and up over the rump. From underneath the hock, push up until the pelt hangs by the skin that is fastened to the tail and anus. It will be necessary to use a knife to remove the pelt around the tail. Carefully skin around the tail and allow the pelt to drop. Remove the front feet. Wash the carcass thoroughly before eviscerating.

Gutting a Sheep

PREPARATION: Whether you used a horizontal or suspended skinning method, now you remove the head at the joint closest to the head. If the animal is not suspended,
suspend it now by tying a rope tightly around both hind legs and hanging it from a branch or beam 8–10 feet high. Rinse the carcass thoroughly with a hose or by sloshing buckets of water over it.

**The Gutting:** Loosen the large intestine by cutting around the rectum deep into the pelvic canal. Pull the rectum outward, cutting any remaining attachments. Tie a piece of string around the large intestine near its opening, and let it drop into the pelvic cavity. The pelvic bone is not separated. Locate the end of the sternum and split the breastbone with a knife or saw. Do not cut into the body cavity. Make a cut through the male's genital area (cod) or female's (udder) into the pelvic cavity. Make this opening large enough to insert your hand. Insert the knife handle inside the body cavity and, with the blade extended outward, open the body cavity to the opening made at the brisket. Allow the paunch and intestines to roll out and hang down. Do not let them fall, as the esophagus will tear and spill its contents onto the carcass.

Find the loosened large intestine and pull it down past the kidneys, leaving the kidneys intact. Remove the liver by reaching behind and pulling it, while cutting the connective tissue. Examine the liver for any abscesses (yellow or white pus) or scar tissue. Remove the gall bladder from the liver by cutting beneath it and pulling. Be careful not to allow its contents to spill on the liver.

Pull the paunch and intestines outward and cut through the diaphragm (the thin sheet of muscle and white connective tissue that separates the lungs and heart from the stomach and intestines). Make this cut at the edge of the thin muscle. Sever the large artery at the backbone and pull downward, removing the heart, lungs, and windpipe with the paunch and intestines. Cut across the top of the heart and separate it from the lungs.

Wash the heart and liver carefully in cold water and place them under refrigeration. Remove the kidneys and kidney fat, and wash the inside of the body cavity thoroughly.

**Aging Mutton**

**Preparation for Hanging:** Rewash the outside. Carefully trim away any pieces of adhering skin or wool, any bruises, hair, or manure spots. Lamb carcasses are not usually halved and quartered before cooling because of their relatively small size. In cool weather (28–35°F), the carcass can be wrapped in a sheet, hung, and chilled in a well-ventilated shed, but don't let it freeze. Freezing within 1 day after death may toughen the meat. One way or another you need to accomplish prompt and thorough chilling of the warm carcass. After it has been chilled 24–48 hours you can commence with cutting it up.

**Time to Age:** Extended hanging (up to 3 weeks) tends to dry out the meat but also risks spoiling. I recommend you aim for the middle range in aging that older sheep. Hang the meat only about 10 days—and that only if you have facilities to keep it above freezing and below 40°F.

**Cutting Up**

There are several "correct" ways to cut up a sheep carcass. No single method is required or even recommended. One old-timer told me, "The meat of either sheep or goat is cut up pretty much like rabbit. Peel the shoulders right off the body. Cut through the thigh joint to separate the hind legs from the body. If you are careful you can get some steak off the back from the strip along each side of the backbone—the tenderloin, from the hams (the hind 'thigh'), and the shoulders. Make big chunks into roasts, and grind odds and ends for hamburger."

Here are the USDA directions—a lot more complicated: Begin cutting the carcass by removing the thin cuts—the breast, flank, and foreleg. Lay the carcass on its side and mark a cutting line from the elbow joint of the foreleg to the front part of the hind leg. Most of the flank can be removed by starting the cut between the legs at the cod (or udder) fat where the flank begins. This cut is made in a straight line from the front of the hind leg to the elbow joint. More of the rear flank and lower ribs can be removed by making the cut higher, near the hind leg, if that's your preference. However, the cut across the lower shoulder should be as close to the joint on the foreleg as possible to leave the shoulder roast large.

After removing the thin cuts from both sides, remove the kidneys, kidney fat, and diaphragm, if not removed at slaughter. Turn the carcass over on to the cut surfaces and remove the neck. Cross sectional cuts make neck chops; or the neck may be cut off flush with the top of the shoulder and added to your stew or ground lamb bowls.

The trimmed carcass is separated into 4 primal cuts, each with different characteristics. A cut between the fifth and sixth ribs removes the shoulder. Another cut between the 12th and 13th (last) ribs separates the rib from the loin (the 13th rib remains in the loin). The loin and legs are separated just in front of the hipbones by cutting through the small of the back where the curve of the leg muscles blend into the loin.

Split the legs through the center of the backbone. Trim the flank and cod (or udder) fat off. Remove the backbone from the leg by making a saw cut approximately parallel to the split surface of the backbone and 1 inch below this surface. Saw approximately 1 inch deep, or until you feel a slight slippage when you cut through part of the hipbone.

Be careful not to saw all the way through the hipbone. Insert a knife into the saw cut, find the "slip" joint between the bones, and cut underneath the backbone to complete its removal. Cut off the lower shank bones by sawing where the tendon enters the muscle.

The leg may be further trimmed by cutting through the knee or "stifle" joint to remove the shank. This joint is located about halfway between where the muscles of the shank end and the muscles of the lower leg begin. Cut into the tissues over the bones until you locate the joint and work the knife through it. Continue cutting straight across the heel of the leg.

Several sirloin chops may be removed by knife and by saw cuts made parallel to the cut separating the leg from the loin. Split the loin through the center of the backbone and remove the flank about 1 inch from the loin "eye." Loin chops are made by cutting perpendicular to the backbone. Usually chops are cut ¼–1 inch thick. Doubles, or "English" loin chops, are made from a loin that has not been split. The flank portion may be ground or made into stew.

The rib should be split somewhat differently than the other primal cuts. The backbone is not split but is removed by cutting through the ribs along the ridge where they join the backbone. Continue cutting close to the backbone to
separate 1 rib section. Repeat this cut along the opposite side of the backbone to separate it from the other rib section. Remove the breast portion by cutting approximately 2 inches from the rib “eye.”

Rib chops are easily made by cutting between the ribs. The breast portion may be barbecued in a single piece or made into riblets by cutting between the ribs. After splitting, the shoulder may be roasted as is, made into chops, or boned and rolled to make a more easily carved roast. Arm chops should be made first by cutting parallel to the surface made when the foreleg and breast were removed. Only 2 or 3 arm chops should be made. Blade chops are made by cutting between the ribs and sawing through the blade and backbone.

**Boneless Shoulder Roast:** First remove the ribs and backbone by cutting closely underneath the ribs following their curvature, then cutting along and over the backbone and neck vertebrae to remove them. Start at the rear surface and cut along the lower edge of the blade bone to lift the underlying muscles, exposing the blade bone and arm bone. Cut along the edges of these bones and then lift the overlying meat and cut close to the top surface of these bones to remove them. The blade bone has a ridge that runs close and nearly parallel to its shorter edge. Try not to cut through the skin surface when cutting over this ridge. The boneless meat should be rolled so that the shoulder “eye” is lengthwise in the roast. The shoulder eye is located under the flat surface of the shoulder blade. Roll the meat as tightly as possible, then tie securely with a strong twine or cord. The boneless shoulder may be made into a pocket roast and stuffed with ground lamb or other dressing. The edges of the meat are laced together after stuffing.

The lower Shank bones of the foreleg are removed by cutting or sawing through the joint. The foreleg and hind Shank are often barbecued, cut into stew, or boned and the meat ground.

**Preserving Lamb and Mutton**

**Freezing:** Ideally, lamb or mutton cuts should be used within 6–9 months after freezing, ground and stew lamb within 3–4 months. They probably would last longer, but we experience preparing sheep meat insist that burning the mutton fat is what creates the strong taste. They say, if you roast at no more than 325°F, that offensive taste can be avoided.

**Sheep Fat:** Trim away and/or cook away all the sheep fat. It has the highest melting point of all the fats and is high in cholesterol. It makes the best candles and fine soap, too, though better if mixed with softer fats. If you pressure-cook the meat until all the lean meat can be easily separated from the bone and fat, then use the meat in other recipes, you can eliminate the presence of fat almost completely. That's also a good way to cook tough meat.

**Mutton Burger or Sausage.** When making this do not include any portion of sheep fat. Make mutton burger out of 100 percent lean meat. Make sausage out of seasoned plain lean, or by mixing in a proportion (one-third is typical) of lard (pig fat).

**Pressure-Cooking Tough, Old Mutton.** Cut into pieces that will fit into the cooker. Soak 1 hour. Then cook 15 minutes at 15 lb. of pressure.

**Lamb/Mutton Seasonings:** Lemon juice, rosemary, mint, tarragon, dill, and currant jelly are the ideal seasonings for lamb. Mutton is appropriately cooked with much attention to generous and interesting seasonings. Other possible good lamb-mutton seasonings are crushed mint leaves, fenugreek, marjoram, thyme, sage, savory, soy sauce, fresh parsley, beef bouillon cubes, chopped green pepper, Worcestershire sauce, chili sauce, ground allspice, nutmeg, sour cream, tomato sauce, green tomatoes and green tomato juice, Tabasco sauce, and red wine—a combination that can be done.
Clean intestines really well. Coil them tightly around lumps of intestinal fat. Bake. Cut into sections and serve. The tripe will be crispy on the outside. The fat seasons and tenderizes it.

**FRIED BLOOD AND ONIONS** Carefully save the blood. Cook it as soon as possible (within 24 hours) because it spoils quickly. Fry with onions in a cast-iron skillet. When cooled, it has the consistency of liver.

**TRADITIONAL ENGLISH SHEEP’S HEAD** Soak the head overnight in salted water. Then rinse thoroughly. Boil slowly for a couple hours with an onion. Cool, separate the meat from the bone, and use the meat in any suitable recipe (for example, any recipes for old stewing hens).

**SHEEP TONGUES** Soak in salt water. Rinse. Boil until tender. Bake in caserrole layered with bacon and vegetables, until vegetables are tender.

### Conventional Lamb/Mutton Recipes

**LAMB CASSEROLE** Trim fat off of 1½ lb. stewing lamb. Cut meat into cubes. Heat 2 T. oil and saute 2 quartered onions until golden. Add meat and brown. Sprinkle with 4 T. flour and cook, stirring gently, for 1 minute. Add 2 ½ c. water, 1 t. salt, and ¼ t. pepper. Bring to a boil, then add 5 T. tomato paste, 1 clove finely chopped garlic, and a bouquet garni (bay leaf, thyme, and parsley tied in cheesecloth). Bake 1 hour at 350°F. Then add ½ c. fresh or frozen peas and bake another 20–30 minutes. Serve sprinkled with parsley. Serves 4.

**SCOTCH BROTH (A MUTTON SOUP)** Trim all the fat from about a ½-lb. neck of mutton or some other piece. Put it in your pan, cover with water, and bring slowly to a boil. Skim off the scum and then add salt and pepper and about 2 oz. of pearl barley. Simmer 1 hour. Add 1 diced onion, 2 leeks (if you have them), some chopped parsley, 1 large carrot, 1 small turnip, and a few sticks of celery. Continue cooking another hour. Cool. Take out the meat, remove the bone, cut up the meat and return it to the broth. Reheat, add a little chopped parsley, and you have your soup.

Here are 4 recipes from The Good Food Guide to Washington and Oregon, edited by Lane Morgan (Sasquatch Books, 1992). You can look at these and see how recipes really ought to be! But Lane says, “These recipes should be credited to Angelo Pellegrini.”

**LEG OF LAMB ROAST** “The preferred flavoring agents, in addition to salt and pepper, are garlic, fresh rosemary, capers, parsley, lemon juice, olive oil, and dry vermouth. For a leg of lamb roast proceed thus: Remove the bone. In the resulting cavity, spread 2 T. of the following all coarsely minced together: 3 cloves of garlic, a dozen capers, and leaves of parsley and rosemary. Salt and pepper. Sprinkle over the whole 1 T. olive oil and the juice of half a lemon. Add a sacramental spray of dry vermouth. Enfold the bone in the cavity, tie the whole securely with heavy twine. Roast it in a 350°F oven in a pan just large enough to contain it. Baste occasionally with its own juices enriched with a bit of vermouth.”

**LAMB SHANKS OR RIBS** “Place lamb shanks or ribs in an iron skillet in the oven preheated to 375°F. When about half done, drain out all the fat. Sprinkle with olive oil; add coarsely cut garlic, a few sprigs of rosemary, a squirt or two of lemon juice fired with a squirt of Tabasco. Salt and pepper to taste. Give the skillet a shake, return it to the oven and reduce the heat to 300°F. In a few minutes the ribs will be done. The shanks will require more time.”

**LAMB CHOPS AND LAMB STEAKS** “For lamb chops and steak: Mince finely garlic and rosemary. Put in a small bowl, add olive oil and lemon juice. Remove what fat you can from the chops, rub them with this mixture, salt and pepper to taste, and cook them in a skillet rubbed with butter. When about done, spray them lightly with vermouth.”

**LAMB FRICASSEE OR STEW** “For a fricassee or stew, cut neck bones and meat from the shoulder in small pieces. Dust them with flour flavored with salt, pepper, and curry powder. Using a heavy skillet, brown them in olive oil. Remove them with a slotted spoon onto a dish. In the same skillet, with no additional fat, saute onion, celery, carrot, and potato, all coarsely chopped and in what quantity desired. To 1 c. stock add a squirt of Tabasco, the juice of half a lemon, 2 T. tomato sauce, and 1 scant t. arrowroot for thickening. Stir well and pour over the saute. The sauce should be dense but fluid. If too dense, add some vermouth. If too fluid, add more arrowroot. Return the meat to the skillet, mix thoroughly, clamp on the lid, and simmer over low heat for 5 or so minutes.”

### Pig

Pigs are the most civilized barnyard animal there is, yet probably also the ugliest. But Stephen Scott believes that pigs can look beautiful to those who love them and that caring for their welfare should be approached “from a spiritual perspective.” My correspondence about pigs with Stephen started when I got his letter asking the price to mail-order a copy of this book. His letter was well-written, a pleasure to read—such an honest, down-to-earth guy—and in it he mentioned he was an organic pig grower. Starting at that letter, it occurred to me that this articulate man, who had raised so many more pigs than I, could probably teach me a lot! So I wrote and asked if he would add to what I already had about pig raising for the new book.

Stephen wrote back: “I got your letter as I was putting the final touches on, of all things, the new hog fence. Yes, I would be glad to deliver your readers from the folly of store-bought, factory-raised food into the wisdom of homegrown, raised-in-the-dirt food.” And then Stephen seriously
set out to explain in writing for me, and you, the things about organic pig growing he felt we really needed to know.

He wrote, "I believe that pigs are people too, and should be treated with respect. If you spend some time with your pigs, you will, no doubt, come to respect them as the magnificent creatures that they are. Watch them work out in the pasture for a while. They are unmatched for sheer brute strength, when they put down their snout and root in the ground. Aside from the good-natured squabbles at the trough, they exhibit a sense of togetherness that humans in confinement would be hard-pressed to match. They have individual personalities too, and my wife and I make sure to name them according to their personalities.

"We enjoy watching the pigs the whole while we have them, but when they are little we must watch them more—not only in order to detect signs of emerging personality but also to see if they seem content. The search for emerging personalities will insure that the right pig gets the right sister-in-law's name, and the search for contentment will insure that they will not go to bed hungry. You can tell contented pigs by the sounds that they make and by how they look. I should mention, at this point, that you should give them a week or so to settle in and become comfortable with their surroundings. After that, contented pigs will make mellow sounds punctuated with boisterous good-natured sounds. I realize that this is not a scientific evaluation of pig sounds, but, just listen to them. Dirt on the snout, as a measure of contentedness, depends upon where the dirt is. No dirt means not happy. Dirt half way up the snout means happy. Dirt up past the eyes means ecstasy.

"I have heard that it is not a good idea to name and make pets out of animals raised to be eaten. All that I can say on that subject is that if you have given the pigs a good life it is not a problem. Give them as much fresh air and fresh water and good food and respect and consideration as you would any other family member, and sending them off to the butcher will not be a problem. Consider the kind of life that they would have had. Everybody else I know of raises pigs for a living—and eventually became commercial pig ranchers! Martha Wells of Normangee, TX, "My husband did not know anything about farm life before moving here. And, with his working off the farm, a lot of 'man things' are left to me. I want to let your readers know, a woman can do a lot more than she suspects! I knew how to string the hay baler and run the tractor, so guess who gets to do the hay baling each year! (After getting tired of having to fix the baler after the men used it, I took over that job.) I run commercial... cows. When they get penned and wormed, branded, or whatever, I do the penning and separating. Actually crawling in to castrate or give shots—yes, I occasionally do lose my nerve and require help! I always assist in the delivery of my brood sows and castrate my own boar pigs also."

Nevertheless, everyone should be careful... mature boars can be dangerous, and sows with litters should be treated with caution.

Getting Started with Pigs

PERIODICALS: There isn't a folksy magazine specialized for small-scale owners and lovers of Ms. Piggy. But check out these more pro-oriented ones: National Hog Farmer costs $14.75 for 12 issues/yr: 952-851-4660; 7900 International Dr., Ste. 300, Minneapolis, MN 55425. The Pork Industry Group (PIG), a branch of the National Livestock and Meat Board, offers info on research, catalog, and free recipes: 312-467-9520; 444 N. Michigan Ave., Chicago, IL 60611. Kansas State Research and Extension: 24 Umerber Hall, Manhattan, KS 66506; www.oznet.ksu.edu/library/ has a terrific swine research program and extensive pamphlet offerings.

VOCABULARY

Barrow—a castrated male pig
Boar—adult uncastrated male for breeding
Drift—herd or crowd of swine
Farrow—a sow gives birth
Feeder—a 40-lb. weaner pig that will be fed up to 200 lb.
Gilts—a female that hasn't had babies or has had only 1 litter (after getting pregnant the second time, she is called a "sow"; an "old gilt" is a female that got to be 1 or 2 years old and never bred)
Hog—grown pig arrived at butchering weight of 200 lb.
Piglet—newborn pig
ZONING: Stephen: “Local governments have rules concerning what animals can be raised in what areas. Some housing developments have rules that are stricter even than the zoning rules. Check with the local unit of government and find out if you can raise pigs where you live. Remember that the smaller the amount of space you have for pigs, the more concentrated the smell is likely to be. But if you have the means to build an attractive pen and fence, it may just be that your neighbors may become your customers. At least, talk it over ahead of time if you have a neighbor in close proximity to the prospective pen. If it turns out you can’t raise pigs where you live, move.”

BREEDS: Pig prices, like cow prices, fluctuate depending on supply and demand and whether they’re generic pigs or brand-name and registered. There are different kinds of pigs, but they’re all pig. So it’s up to you if you want to buy pedigreed animals for a family meat plan. Names of some established breeds are Berkshire, Chester White, Landrace, Poland China, Duroc, Spotted Swine, Hampshire, and Yorkshire. If you want to have a breeding operation on pasture, you’re best off with animals that were raised like that—no matter what breed they are.

Stephen: “We could go into a lengthy discussion of what breed of pigs you should buy, but I believe that would be an exercise in futility since almost all modern breeds will produce pork quite nicely. What will determine the breed that you buy is more likely to be what breed is raised in your area. . . . But don’t buy novelty breeds, such as Vietnamese potbellied pigs. They are bred more for pets than pork, are quite expensive, and are not a good producer of pork as we know it. What will be more of a consideration is the type of pig that you like the looks of. If you don’t like the looks of the little one, then you won’t like the looks of it when it grows up.

“. . . beauty is in the eye of the beholder. My aunt has raised pigs for many years. She raises many feeder pigs from 20 or so sows. She keeps sows for 6–8 years, and as each year goes by the sows get bigger and as far as I am concerned, uglier. But last time my wife and I went to see her, my aunt took us out to the pig barn and showed us her prize sow. It was a 600-lb. behemoth with an 18-inch-long snout and 12-inch-long ears that hung down over the eyes. She went into the pen and scratched this monster behind the ear and asked us, ‘Isn’t this the most beautiful pig you’ve ever seen?’

“Well, that sow had given her 12 little ones in each litter and 3 litters a year for the last 7 years. I admit there is a certain beauty in that. So find a pig you like the looks of and you will become more attached to it as time goes on.”

Of Lean and Fat. Some growers are really concerned about the trend of selection that has taken animals that were brought to North America by the Conquistadors and after that traveled along with European pioneers—in essence, tough, independent, outdoors critters—and transformed them into dependent, sickly, hothouse animals. Part of the problem is that the latest thing in pig genetics is super-lean genetic lines. The problem with these is that they are so lean they are not a good choice for pigs to go on pasture because they don’t have that blanket of fat to keep them warm. And fat and reproductive hormones are linked. A sow must keep up a 20-percent body fat ratio if she is to be fertile and conceive, farrow a big healthy family, and give them plenty of milk. That’s just how pigs are. Another problem with the modern pig is that it is descended from uncountable generations of hothouse pigs so qualities of hardiness and resourcefulness have often been lost. Indeed their requirements for food and care virtually demand a confinement lifestyle. But if you’re going to raise sheltered pigs, then super-leans are not so bad. Tamworths are good old-time hardy hogs for pasture-raising.

FEEDERS: Most families raising a pig or more for their family pork supply buy feeder pigs in the spring or summer and raise them to butchering size off the summer garden surplus and fall harvest scraps as well as other feeds as needed.

Stephen: “Feeders are pigs that weigh around 40 lb. . . . a set weight that the pig-raising industry sets to provide a base price for feeder pigs. Many times you will be able to buy a 50-lb. pig for nearly the same price as a 40-lb. one because the farmer is docked in price for pigs that are over the standard 40-lb. weight. Large growers want all of the feeders at 40 lb., so that they will all reach 200 lb. at the same time when they sell them. . . . they will be docked some for pigs over 200 lb.”

When to Buy. “Depending upon how you feed them, it will take about 4½ months to turn a 40-lb. feeder pig into a 200-lb. butchering pig. When it’s best to buy your feeder depends on where you live. If you live in the north, then you will want them over the summer. Pigs have a hard time, in the northern climes, putting on weight and keeping themselves warm at the same time. Add to that the fact that they aren’t able to go outside and forage for any of the food that they need, thus costing you more money to raise them. And winter pigs have to have a much more elaborate home and very likely need to be confined in a building, which may cause health problems. I live in Northeastern Wisconsin about thirty miles west of Green Bay. We buy our pigs in late June or early July so that they are ready to butcher in mid-November. If you live north of here you may want to consider buying them sooner and if you live south of here you may buy them later.

“If you live in the deep south, it may well be that you will want to raise them over the winter. In the south the hot weather of the summer may cause them to not be as happy as they would be in the cooler winter, and, as everybody knows, happy pigs will tend to be healthy pigs.”

New Pigs. The time pigs are most likely to act weird and emotionally upset, to hide in a corner of the pig house and refuse to come out, or to take off and escape through your fences, are when you first bring them home. Stephen: “We know enough after 10 years of raising pigs to make sure that we stay home for the first few weeks after they have their little truck ride from the neighbor’s place to ours. We lock them in the building for the first couple of days and feed and water them in there.”

Runaways. Stephen: “This year everything went wrong. We got 3 pigs. Two of them had their transmissions lock up in forward gear and they burst through our fence. It took us 2 days to round up the 2 escapees and bring them back home. It cost my son a case of poison ivy, my wife
2 afternoon naps, and me—well, I had to listen to a lot of criticism about my choice of fences. No serious damage was done and the 2 recalcitrant porkers were soon back home. But then the third one must have heard from the others how great it was in the wide open spaces, because his transmission locked up in forward gear, and he too burst through the fence. He is not back home and it has been 3 months. I caught sight of him once this summer down by the woods, but he outsmarted the dog and me. Try as we might we could not get him.

To recapture a runaway pig, Stephen advises: "Bear in mind that pigs need water at all times. Check around in the area wherever there is water. Check for tracks and signs of rooting near water. If it happens to be a dry summer, you might have a chance of recovering your runaway. Unfortunately for us, this has been a wet year and it would appear we have lost this guy. No doubt, he has paid a price for his freedom already; it is unlikely that he will be able to survive the Wisconsin winter."

Home Sweet Home, For Pigs

Stephen on planning: "I had a farm background and so did my wife, and we had 20 acres and buildings, so we decided to raise some pigs. We were afraid of nothing in those days. We just went to the neighbor's and bought 3 nice white feeder pigs: 1 for ourselves and 2 to sell. Just a short while before we were to pick them up we realized that we hadn't thought of where we would put them: neither house nor fence did we have! That's how I learned that planning ahead eliminates mistakes. It is important to pick a good site. If you choose right the first time, you will not have to go through the hassle of moving the whole she-bang to another site. Think about it, take a walk around your place and consider different sites and different reasons to put them either here or over there."

So, combining the wisdom of Stephen with that of Mike and Carla, here are the essential points of pig housing site selection.

**Pig Housing Site Selection**

1. **Consideration of Neighbors**—Put pigs where they won't offend a neighbor. Stephen: "If you live near a neighbor consider him or her in your plans as well. Life will not be too joyous for you if you have an irate neighbor to contend with."

2. **Downwind from House**—Stephen: "We started out with the pig field southwest of the house. And if you get any breeze at all in the summer here in Wisconsin, it will undoubtedly be a southwest breeze. So we got the full aroma of pig wafting over us all night long for 2 years until we finally moved the pen to the northeast of the house."

3. **Shade**—Pigs can sunburn. No matter how warm or cool it is, they must have the option of a shaded place to rest in.

4. **Provide a Wallow**—Pigs are also at risk for fatal overheating. Allow space for their mud wallow. The wallow can be a matter of survival for them. That's why, in hot weather, pigs roll in mud—it's to cool themselves. Some sophisticated pig operations provide a misty spray to cool the outside pig runs. But Barb advised, "Never hose a pig with cold water when it is hot. It will put the animal into shock and it will die." Don Fallick, Davenport, WA, explained: "Since pigs do not perspire, their only method of cooling off is the pig wallow. Pigs do not actually prefer mud, and they will seek cool water to wallow in during hot seasons if given the chance. But you must give them some place to cool off, for their health. If your pigs are housed outdoors, in a hut, this is no problem, but if your sty is inside a large barn, some provision must be made for a hog wallow. If you don't have running water to the barn, at least in summer, you'll find yourself hauling an awful lot of water to the pigs."

5. **Clean, Abundant Drinking Water**—They must have a lot of water in their trough. When planning where to put them, if you make sure it's somewhere that you can get water to through a hose rather than by hauling it in buckets, you'll be glad for your foresight.

6. **Consider the Lay of the Land**—Because pigs like to play in their water and make mud, you should put their housing in a high, dry site, above their water, above their mud, so they'll be able to sleep warmly up out of the damp.

7. **Shelter from Cold**—If you have chilly, or outright cold, weather, they need a shelter such as a little house with a wooden floor or dirt with straw on it. The colder your weather will be, the better-built their housing needs to be. It could be one end of a shed or in a section of your barn.

8. **Choose from Indoor/Outdoor Options**—You have 3 basic variations to choose from: all-indoor, combined indoor-outdoor, or all outdoor with some shade provided. There are variations on those basic systems: You can either keep them confined in indoor quarters all the time, or just in bad weather. You can connect the indoor quarters chicken-yard-style with a door leading to a fenced outdoor run of whatever size is feasible for you, from a small run to a large pasture. An outdoor run 20 feet on the side would be fine for 1 pig. You could give more for more pigs. If you have a pasture for them you could just put their housing in the middle of their pasture. Or you could locate it along the fence side so there can be a people door on one side and a pig door to their pasture on the other. If space allows, pigs will choose 1 corner of their run or field for their pottying area.

9. **Loading Facility**—Plan and build a way to load them onto a truck. You'll need that for trips to the vet, or the meat cutter, or to a new owner. This should consist of a corral, which leads to a chute, which goes into a loading ramp. You can have one of these for all the livestock on the place with a system to get the pigs there, or 1 just for the pig housing.

10. **Pastured Pigs?**—Yes, this is an excellent option. Pigs give great weeding service. Is there a potential future garden spot you want de-weeded, plowed up, and fertilized? They're also good grazers. So you can put them where there is good stuff growing or where you've planted a fodder crop for them. Pigs on pasture will go far toward balancing their own diet, and will live in as nearly natural a way as they can manage. For parasite control they do best with a portable house like an A-frame on sled runners and rotated pastures—keeps pigs off a particular pasture segment at least 1 year before using it again. For example, there might be three 4-acre patches in your rotation, with crops grown on
Animals are as much God's creation as we are. How we treat them while they are in our care says a lot about what kind of people we are.

**PIG HOUSING**

**Agribusiness Style.** Stephen: “I don’t pretend to be an expert in the new high-tech means of pork production, but I have talked to the people in this area who raise pigs in this fashion. They have 500 acres of corn, to which no cultivator has been set. Weeds are killed and crops are fed through the miracles of chemistry. They weren’t making enough money selling the corn so they decided that if chemistry could help raise corn, it could also help raise pigs. I was not allowed into the pig-raising building while the pigs were in there, but I saw it and had it explained to me while it was in the construction phase.

“My brother-in-law showed me around. He was building it and marveled at the efficiency of the whole operation. Three rooms: in one the sows; in another, the nursery; in the last, the feeders. He showed me the shower room and the office. One man runs the whole thing. He takes a shower before he starts the day’s work and, of course, a shower at the end of the day’s work. He showers so he doesn’t bring in any diseases with him.

“Paperwork is kept so that the sows that don’t meet the average can be culled. Little pigs are born, nursed, and fed up to butchering size without ever seeing the sun or feeling the earth under foot. They are born in that building and they will spend their whole life there. It is a pork factory.

“The pigs are given a balanced ration of feed, but it is not their choice what they eat. Their likes and dislikes are not considered. Profit is the only consideration. Also, the pork you eat is laced with antibiotics. [Pigs are fed more antibiotics than any other type of animal.] In nonorganic commercial operations, low doses of antibiotics are routinely fed to cows, pigs, and poultry, all of which are raised in confinement nowadays. It necessary to do this to insure that if a disease starts in one of these confined animals, it will not spread to all of them in the building. It is done also to increase weight gain, much of which is only extra water in the meat in my estimation. These days the only way you can get the good-tasting pork from happy pigs is to raise it for yourself—or buy it from an organic pig grower.”

**Comfy Pig Housing.** Don Fallick said: “Pigs need to be protected from the heat and wind, and, to a lesser extent, from the cold. Their subcutaneous fat does protect them from cold temperatures, especially if they are housed in a cabin small enough to trap their body heat. A proper pig cabin should be large enough for the pig to turn around in. ‘A-frame’ huts are quite common where pigs are kept outdoors. In an indoor barn, the pigs will still need a small enough sleeping area to keep comfortable.”

Stephen described the building of his comfy pig housing to me: “I wanted a pig house with a dirt floor—no bottom on it—so it was important that it be situated high and dry. I wanted the house in a good permanent site, with a movable fence. So I took the tractor and disc and worked the area around where it was to be built . . . to make it easier to shovel the dirt into a mound about twice as wide as the house would be. Around the house I wanted the ground to gently slope away. If you have a slope, then when you dump out the water trough to clean it, the water will run away from the house. The pigs will tend to want to wallow in the discarded water and make a small sea of mud near the trough. If you plan ahead and do the extra work to make a mound like that, then you will have a neat and tidy feeding area and a dry sleeping area for your new friends.

“We raised our first pigs under a truck cap. The pigs didn’t mind. They were just as happy as clams poking their heads out of the windows and the rear of the cap. But our second year’s pigs, even though I’d reinforced the cap arrangement, enjoyed knocking their house around so much, they managed to reduce it to rubble by November.

“As luck would have it, the company I work for was throwing out some brand new 3-foot-square plywood pallets. I could not pass them up. I used 10 of them to make a 9 x 9-foot building with two 3-foot doors . . . on each end. That’s three pallets on the side, and 2 on the ends, with the middle part open to make 2 doors. For the roof I used six 10-foot-long 2 x 6s for rafters, spiked to the pallets. To the rafters I nailed 2 x 4s laid the 4-inch way and covered this over, first with tar paper and then with rolled roofing. I tarred the seams.”

**Converting Existing Outbuildings.** “If you have an existing outbuilding you can use that, and save yourself a lot of building problems. But if the pigs can get their noses into any holes near the bottom of the wall, they will eventually destroy that section of wall. So go in there and cover up any holes in the walls. If you are going to give them a fenced outdoor yard, they only need enough room in the building so that they can all lie down and stretch out. If space is tight, feed them outside.

“If you don’t have a suitable outbuilding for them, assess your building skills, scrounging skills, financial situation, and ingenuity. Everybody can have a nice comfy pig building. It is up to you to decide if you’re the building, scrounging, or buying type.”

**If You Can Build.** Stephen: “You can build an A-frame affair that will suit your purposes nicely. Pigs don’t mind what kind of a house they live in as long as it keeps them dry and cool, or warm, as conditions warrant. Most pig-raising books suggest that the building should have a floor in it. I don’t agree. It can get quite cold and wet in Wisconsin in
the fall, yet my pig house has never had a floor in it. Instead, I provide lots of straw, or old grassy hay that Jersey Belle, our milk cow, turns her nose up at. The pigs burrow into that. The pigs always make sure they don’t get too close to the cold ground and still manage to cover themselves.”

If Scrounging Is Your Skill. Pigs are indifferent to appearances. Function is all that matters. Stephen: “You can scrounge up a perfectly good pig building such as the old truck cap we used the first 2 years. I have seen pigs raised in a 1966 Buick LeSabre in a more rustic area of our fair state. When it comes to raising pigs on a subsistence level, the sky is the limit.”

Buying Ready-Made. “You need not be ashamed to buy your pig house ready-made. In every rural area there are handymen who are not beneath building pig housing. If you can’t find a handyman, go to the local high school and seek out the industrial arts teacher or the agriculture teacher. These guys don’t make a fortune teaching and have the tools and the skills as well as the summer off in many cases and may welcome the opportunity to show off a little. In our area there are people who build gazebos and greenhouses and small storage buildings for the city folks. They build them at their home and then transport them to wherever the city folks want them. This would be high end housing for a pig, but if you have the money and don’t want any of the hassle it is not a bad idea.”

Your Pig Loading Set-Up. Stephen: “Our first year of pig-raising, we lacked a loading set-up. At year’s end, after 4 hours of not a little chasing, diving in the mud, and considerable cursing, my family and the neighbor’s managed to get 2 of them in the chicken coop. The third was a more serious problem altogether. It required brute force on the part of all 4 of us to physically drag the beast screaming and scratching, backwards, from the field to the loading setup.

“It’s a well-known fact that pigs will do anything not to go in a direction that you want them to go. I figured out if we were to be successful in loading pigs on a truck they must be channeled into an area narrow enough that they can’t turn around. I would never again try to load them in the middle of a field. So I built the pig house with 1 door that led into the fence and another to the outside world. I nailed boards over the outside door.

“When it came time to call the trucker to pick them up, it was a simple matter to go out at night when the pigs were sleeping and nail a few boards over the openings that led into their field. When the trucker arrived in the morning we took the boards off that covered the door that led to the truck bed. It would have worked great, too, if it were not for the fact that the pigs decided, since they had never gone through that door up until that day, that they never would! So loading was still really hard.

“The next year I dug in 8 cedar posts and bought 4 pieces of ¾-inch plywood. The day before we were going to ship I nailed the plywood to the cedar posts, forming a corral as wide as the loading gate on the truck. We coax them out with a couple of cobs of corn and closed the door of the pig house behind them. It was a simple matter of finding a gate as wide as the corral and pushing them using it on up the ramp of the truck. This is the point that we are still at today. It has been 7 years and the system has always worked well.”

Fencing For Pigs

You have to fence any area for a pig very carefully. Stephen agrees: “The pigs don’t mind what kind of house, or fence, they have, but in this area it is important for you to care. Quality fencing is essential.”

Catching A Pig: There’s an old saying: “As independent as a hog on ice.” If your pigs are used to the slop bucket, so that they know you and look forward to your visits with bucketfuls of that good garbage, all you have to do if they do get out is run get the bucket and they’ll follow you anywhere—even right back into their pen! To catch a pig that isn’t slop-bucket-broke—well, they’re “as independent as a hog on ice” and as hard to get hold of as the one in a “catch-the-greased-pig” contest. You just find yourself a few neighborly football players and try to tackle the pig. Then you carry it, or drag it back by the heels, or whatever your imagination suggests. Even if your pigs will follow the bucket, it’s still best to have good fences; if the pigs manage a few hours in the garden while you’re not home they’ll wipe out your root vegetables. A reader told me that on her wedding day, the hogs got out. She said, “When the hogs get out, you chase hogs . . . guys in tuxedos!”

Pigs on Pasture: Mike is a firm believer in having pigs preweed the garden. We suffer from morning glory, and after the stuff has taken over an area, he fences it off for the pigs to pasture in. Yes, you can pasture pigs instead of feeding them grains if you have enough land. If they are in a small area like your garden, they will plow and fertilize it for you as well as provide your family with the very

842
best tasting and most healthful pork available in the whole world. If you can't find organic pork in your neighborhood (or any other organic meat), there is a very good chance you can become a supplier of it. I have . . . gone from store-bought, factory-produced, unhealthful pork to frolicking, rip-roaring, snout-in-the-ground, tasty, healthful pork. You can do it too. It is no more tedious or time-consuming to raise your own pork than it is to mow, trim, edge, and fertilize your lawn in town."

The biggest problems with feeding pigs in groups, on pasture or elsewhere, are the chance of wasted feed, and also boss pigs that overeat and push away lesser, more aggressive pigs from the feed trough. An answer to that problem is using long feed troughs that everybody gets a fair chance, or, if food is spread on the ground, spreading it over a large enough area that "piggling" it isn't possible. And you can use creep feeders for the piglets on pasture.

**Of Pigs and Rooting:** Pigs are rooters. The wild ancestors of our domestic pigs lived in the forest, eating roots, grubs, and bugs discovered by that excellent nose—as well as grass, and windfall nuts and fruits. That snout is pure bone and cartilage and it makes them happy to use it. Pigs on pasture with fruit and nut trees in it can be darn near self-supporting, especially in the south. In confinement though, the wonderful snout can be a problem for you. If you have an area of rocky ground, Mike says that would be a good place to put a small outdoor pig run since you can't use it for much else and they can't tear it up. Or another answer to this problem is to put a ring in the pig's nose. That inhibits rooting.

**Types of Pig Fencing**

**Steel Panel Fencing.** This is the strongest of all, but the most expensive.

**Stone.** Stephen: "If you have the stone, the strength, and the time, a stone fence works well. Of course, you have to bear in mind that it is permanent. If you decide that stone is the way to go, you will want to choose some ground that is no good for anything else. You won't be able to make it large enough to use as a pasture, so you will have to provide all the pigs' feed. Its function will be to contain the pigs and not much more. It may require maintenance each year since the pigs will try to undermine the walls, and the frost will play havoc with them, too. If you are that special kind of person who likes to work with stone though, go for it. A stone fence can be a thing of beauty if it is done right. Since I have no skills in stonework, no time, no stone, and need to move their pasture each year, you are on your own as to how to construct it."

**Wood.** An entire fence made of strong wood panels works better than wire, but it's more expensive unless you can scrounge. Stephen: "I can tell you a little more about wooden fences. Like a stone fence, this is permanent; you will not be able to easily move it from year to year to change the pig's pasture area. You can cut down on the amount of wood you have to buy if you can do some scrounging. A friend of mine made a nice wood fence for his pigs by scrounging up wooden pallets and making a modular affair that worked pretty well. He scrounged pallets and nailed them top and bottom to scrounged 10-foot-long 2 by 4s. He had to put a post in every 10 feet because pigs can put a lot of pressure on a wood fence. He huffed and puffed to make the fence, what with posts every 10 feet. He had to do minor repairs on it weekly, and major repairs between each new batch of pigs. That is the kind of guy he is—he loves his wooden fence. If that is the kind of person you are, think wood."

**Woven Wire.** Fence with "hog wire" if you're going to use wire. This is a woven wire. Pigs don't need as high a fence as other large stock, but their fencing must be stronger, and it must be protected below the ground. You can either dig a trench and set your fence in concrete, or bury the bottom part of your wire at least 6 inches underground. Or you can stretch barbed wire along the bottom of your posts. But I'll tell you from experience that even hog wire is liable not to work. The pigs will go through that wire more and more as they get bigger. They'll break holes even in the hog wire, and you'll have to go out with pliers to twist the broken ends back together.

The problem with breaking wire can be solved by putting a 2 x 10-inch board between the posts tightly right along the bottom. But if you've got soft dirt, your pigs can dig under the boards. If you can choose rocky or hard ground, it will help prevent that digging. Nail up a board also between the posts along the top of the fence. That way they can't pull the fence wire down by climbing onto it.

Here's Stephen on woven wire: "My mother used to make woven-wire fences in the beginning of her pig-raising days. She had the money to buy the wire and the time to dig the post holes. Woven wire is quite expensive unless you can scrounge used wire or buy it at auctions in your area. The advantage of woven wire fences over wood fences is that the posts can be placed farther apart, thus requiring less of them. The problem with woven-wire fences is that, no matter how stout the wire, pigs will eventually demolish it, or go under it. You will have to keep an eye out for places that the pigs have softened up. They always root near the fence first and will eventually manage to make a mini Grand Canyon in one place. The grass is always greener outside of the fence, and they keep rooting outward and eventually they will get their snout under the wire and squirt out of the fence. You can delay their escape by nailing old posts or planks to the bottom of the wire. A woven-wire fence is time-consuming to move each year, and it is expensive to make 2 of them if you intend to take advantage of their rooting by planting either food for them or a garden for you. But if you want a permanent fence that will require some maintenance each year, woven wire will do."

**Electric.** Stephen: "Electric fences are inexpensive to make and easy to move. I have 2 doors in my pig house—one faces north and one faces south. When the pigs are in their south pasture, they come out of the south door and I board up the north door—and vice versa. I dug 6 postholes and planted 6 posts; 2 form the north side of the north fence and 2 form the south side of the south fence. Halfway between them on the north and south side of the pig house and roughly in the middle of the pig house are the 2 posts that form the east and west side of the fence. We use cedar wooden posts, along with enough steel posts so that you have one every 20 feet or so between the wooden posts. I use smooth, lightweight wire rather than barbed because it is cheaper and easier to work with. You will need 8 corner insulators and 2 insulators for each lightweight step-in type post. Get the steel-post insulators where you get the steel posts so they will work together.

"Now take one of the step-in-type posts and step it in the ground near the first corner post. From the spool cut
eight 2-foot long pieces of wire. Now take one of the 2-foot pieces and stick it through the hole in one of the corner post insulators. Then go behind the post and, keeping the insulator to the inside of the post, twist the ends of the wire together. This done, position the wire about the post with the twisted part to the back of the post and the insulator to the front. Take a staple and drive it into the post so that the 2 legs of the staple straddle the twisted wire. This should be done at a height of about 6 inches from the ground. Drive the staple into the post so that it sinks in a ways and holds the wire tightly. Follow the same procedure with the second insulator, but this time nail the twisted end of the wire to the post at about 18 inches above the first one. Do the same thing on all of the 3 other corner posts.

“Now go back to the spool near the first corner post and grab hold of the loose end of the wire. Walk toward the second corner post as the wire plays out of the spool, and when you get there, grab hold of the insulator and give 2 or 2\(\frac{1}{2}\) turns to the right. The hole should be running up and down when you stop turning. Position the wire on the groove of the insulator, making sure that you put it on the groove and not through the hole. The wire may not want to stay in the groove, but don't be concerned about that just yet. Now proceed to the third and fourth post doing the same thing. Walk back to the first corner post with wire still in hand, and stick the end of the wire into the ground near the post. Take out your pliers and cut the wire from the spool, making sure that you will have enough wire to go around the back side of the post and meet up with the wire you stuck into the ground. (Always cut the wire a little longer than you think you will need it.)

“Now go behind the post and take hold of the 2 ends of the wire and twist them together to make the wire quite tight. You should kneel down while you do this because you will want the wire behind the post at the same level as the bottom insulator. Walk to the second corner post and see to it that the wire is in the groove of the insulator, then grab hold of the insulator and give it 2 or 2\(\frac{1}{2}\) more turns to the right. Again the insulator should have the hole running up and down. Do the same thing on the third and fourth corner post. Now you go back to the first corner post and undo the twisted wire. Put the longest end in the groove and twist the ends to make the wire tight. Trim the ends of the wire off with your pliers. Go back to the insulator and, making sure the wire is still in the groove, grab hold of it and give it enough turns to tighten the wire, but not so many as to cause it to break. The wire need not be piano-string tight. Follow the same procedure with the second strand.

“Now that your wire is strung, take the step-in posts and step them in at about 20-foot intervals between the corner posts. When you have that done, take the step-in post insulators, and go to each post and fix the insulators to the wire and then to the posts. Your main goal will be to make sure that the bottom wire is about 6 inches from the ground. If the ground is uneven, it may be necessary to put in an extra one here and there to insure that the pigs can't get under the wire at any point. One last thing that is very important: cut from the spool a 2-foot piece of wire and attach the top and bottom wires of the fence to each other. I left this step out 1 year and it caused much consternation, and that is putting the situation in its very best light. Now to get the electricity to the fence will depend upon what kind of fencer you have. If it is a battery-powered one you can build a little box to keep the water off from it and nail the box to whatever corner post is most convenient for you. If it is a 110-volt one, you will have to decide if you want to run an extension cord to it or put it in a building and run pig fence type of electricity to the fence.

“You will notice that there are 2 terminals on the thing. One is the hot one that will go to the wire, and one is the ground that must be placed into the ground in order to make the system work. It is best to have a copper grounding rod, but if you don't, almost any kind of clean, paint-free post or stake will work. You will have nothing but trouble with your fencer if it is not properly grounded. If you have a dry summer, it may be necessary to pour water around the ground stake. In any event, it is a good idea to make sure that the grounding stake to which you have attached a piece of wire cut from the spool is driven well into the ground.

“To test the fence to see if it is electrified, you could be a sissy and buy a fence tester, which consists of a probe and clear plastic handle with a little light on it. You touch the probe to the wire and if the light lights up you have current on the fence. I'm too cheap to buy one of these things so I use the old-fashioned way: Select a blade of nice green grass, the braver you are the shorter the blade of grass can be. Just flick the blade of grass on the fence. If you get a tingle, you have current. If you get no tingle, place the blade of grass on the wire and slide it on the wire until you do get a tingle. If you don't get a tingle at all, then you have to troubleshoot. When you troubleshoot, start with the most obvious thing first and proceed to the least obvious.”

10-Point E-Fence Checklist

1. See if the fencer is plugged in.
2. See if it is connected to the fence.
3. See if the 2 wires are connected.
4. See if anything is touching the fence.
5. See if the wire that should be in the groove is touching the wire that goes around the post. These last 2 require you to walk slowly around the fence looking carefully at the wires.
6. If you can't find anything wrong with any of the above, it is time to check out the fencer. It should have a fuse in it; check that first.
7. Check the ground.
8. The regulator should be clearly visible on the front of the fencer. It is a little tin-can--type of affair. Pull it out and it should have 2 prongs on it. You should have a spare; put the new one in and test the fence with a blade of grass. If you still get no action take a deep breath and calm down.
9. Check each thing again.
10. If it is still a no-go, take the fencer to an expert.

**Food for Pigs:**

**Pigs Recycle Kitchen Scraps:** Pigs are important because they eat kitchen scraps—garbage. We keep a slop bucket in the kitchen for the pigs. Into the slop bucket go peelings, leftovers, extra milk, spoiled foods from the root cellar, the contents from jars of canned fruit that got moldy, bread crusts—if I burned the bottom of the loaf or accidentally baked it 2 hours instead of 40 minutes—and so on. People have asked me if you can feed chickens scraps of chicken meat or pigs scraps of pig meat. Yes, you can. They don't mind a bit. They both eat meat leftovers, cooked or
uncooked, although our cat and dog get first pick of the cooked meat scraps. They will eat leftover grease too. But I don't give pigs bones. The chickens can pick on them though. I do give fruit cores and seeds to the pigs when I'm working on fruit in the summer. Pigs are tremendously efficient food converters and they'll change all those throwaways into meat and lard.

Mike told me that in some urban areas there is a law that food scraps of that sort can't be fed to pigs. That just boggles my mind. It is so inefficient. Why throw out good food that could feed pigs, which in turn could feed hungry people? When food scraps are ground and poured down a sewer it increases the general sewage burden. When scraps are taken to a land dump and mixed with metals and papers and buried or burned, that's a disgraceful waste of a valuable recyclable material—food. Everybody should be saving their leftover food for recycling just like the country people do. A city could keep a whole army of pigs and chickens growing! Or that food waste could be composted and used to fertilize land from which more plant food will be grown.

The notion that kitchen scraps are unclean is nonsense. We feed our pigs and chickens the leftovers from our home-grown fruits and vegetables. That means our pork, eggs, and chicken have the same high standard of composition as the other food this family eats: "organic." Garbage only looks unpalatable because the peelings and the leftovers, gravy, and grease are all poured together in it. In the later summer and fall we carry the pigs on culls from the garden and root cellar.

So we get little pigs in the spring and feed them all summer on the leavings from canning and freezing. Come fall we butcher the spring pigs, which are just the right size for that, and buy more feeder pigs. We feed them on the food in storage that isn't making it—the green tomatoes that rotted instead of ripening, the apples that went bad, the peels and peelings that are turned instead of ripening, the apples that went bad prematurely, the spoiled pumpkins. About the time that source of food is really slowing down it is early spring and still cold enough for butchering if you pick the right day and the pigs are big and ready. We never need to buy them so much as a cupful of feed and feed them no grain at all. We take the pig's bucket with me to the cellar every few days to check the food in storage. A big pig gets nearly 5 gal. of this food each day as well as extra milk and table scraps. (There is no way I know to feed a pig more than it can eat.) If I fed it 10 gal. it would manage to eat all that too, but 5 is more than enough even for a big pig.

**SPEED OF WEIGHT GAIN:** Pigs gain weight very fast. If you get a little pig in the spring, 6 months later it will weigh 200 lb.—butchering size. If you feed a grain mixture they grow to 200 lb. in as little as 4 months. Corn is the richest food for them, but corn feeding makes for lots of fat. If you keep food in front of them constantly, that's when you get your fastest weight gain. They would go on up to 400 lb. if you let them, but, after 200 lb., the bacon just keeps getting fatter, and there is proportionately more lard and less meat.

That is not what most people need or want.

**OF PIGS AND FAT:** How fat do you want your pig to be? If you pen an animal up and keep rich food like grain in front of it constantly (which is the commercial way to raise them), you're going to have more fat and softer meat than if you let your animal rustle by grazing in a weedy field. Also, older pigs have relatively more fat on them. That's the reason for the practice of butchering at 200–225 lb. When you butcher at not more than 225 lb., you get more meat proportionately. More feeding will not be as efficient: above that weight per pound of feed, your pig will get fatter rather than meatier, and your pig will put on less weight per pound of feed than it did before.

Stephen: "Pigs are a lot like humans when it comes to eating. You will have to be like a good mother to them and see to it that they get what they need and not just what they want. The whole exercise is not to see how fast we can get them to butchering size; rather it is to keep them happy and healthy and put weight on them gradually. Pigs gain weight fast enough as it is. I can't imagine trying to rush them with "high energy/high protein" feeds. But that is just what the experts at your local feed mill will want you to do. Don't allow yourself to be swept up in this whirlwind of salesmanship. 'Salesmanship,' you must remember, is a ship that transports money. The salesman wants to transport your money from you pocket to his. If you have some money that you want to take this scenic cruise between pockets, okay. But otherwise, build a coral reef around your pocketbook so that the feed salesman's ship of sales cannot dock in your peaceful little harbor and fill its hold with your money!"

**CHEAP PIG FOOD:** So, rather than feeding costly food for quickest weight gain (and nonorganic, antibiotic-laced food at that), I prefer using the cheapest possible pig feed for your area. Here that means household slop and oats, which aren't as rich as corn, and pea "screenings" (the weed seed the mechanical harvester separates out from the peas). Peas, barley, oats, weed seeds, etc., are all fine pig food. Some growers suggest that you soak all grains that have a husk, such as whole oats, for at least 2 days before feeding. (See the sections on the individual grains for directions on livestock feeding.)

Ruth Proctor wrote me from New Plymouth, ID: "Once I got the bright idea of asking a potato processing plant for their trimmings and peelings to feed to our 50 hogs and ended up getting 2 tons every day—the only catch being that we had to furnish the truck and keep the peels hauled off. We found out there is no way 50 hogs can consume 2 tons of spuds every day, but it made wonderful fertilizer for our fields—though somewhat sticky."

**FOOD FOR NEWLY ARRIVED PIGS:** Stephen: "You will want to buy a few bags of pig starter. It comes in pellet form and is like candy for the little feeder pigs. It will keep them happy and help them settle into their new surroundings. It might be worth asking the farmer you buy your feeder pigs from what kind of starter he uses, and then get the same brand. But I have found it unnecessary to get the same kind of starter because all of it is so good that the little oinkers can't resist it even if it is slightly different than what they are used to. Suffice it to say that you don't want the pigs to stop eating in the upset of changing homes, as that can lead to serious health problems. But get a pig starter that is unmedicated. The 'medication' would be antibiotics, which are unnecessary if you buy your pigs at the right time of year for your climate and have properly prepared their house for dryness.

The salesman at the feed mill may tell you to give the pigs all that they want of the starter pellets. But since we have them out on the ground so that they can hunt for goodies with their snouts, we start out with three 40-lb.
pigs and three 50-lb. bags of pellets. Each pig gets about 4 lb. of pellets per day. You can divide this up into 2 meals, morning and night, or better yet, 3 meals, morning, noon, and night, just like people.

During the first 10 days the pigs are with you, you can gradually phase them into the home-grown diet that they will be on at your home. Or . . .

**PARTLY COMMERCIAL DIET:** Stephen: "When you open the last bag of pellets, it is time to go back to the feed mill. You should be about 10 days into the pig-raising experience. The salesman will now want you to buy concentrated feeds and corn (both expensive), but tell him that all you want is a couple bags of 'balanced ration': meaning some unmedicated concentrate (protein supplement), oats, and corn. Tell him you want oats and corn in a ratio of 2 oats to 1 corn by weight not by volume. (This should be ground fine and mixed thoroughly) Feeding them this way, you will have to work a little to get what they need in the way of intangibles because they'll need to be on good ground, in which worms live and roots grow. Then they will do well without a lot of expensive additives to their food.

"To sum up: you get a balanced ration for them at the feed store consisting of a protein supplement, oats, corn, and minerals. Or you could substitute some other grain for corn, like barley. Any combination of grains will do, so long as there's enough natural variety in their diet. This year, having the pigs as usual on good ground with lots of greens, roots, worms, garden vegetables and sweet corn to eat, we omitted the feed-store corn and bought only oats and some protein supplement. Caution: If you feed too much sweet corn, your pigs may develop the runs. We fed about 4 cobs a day to each pig for the first part of the time we had them and 8 cobs a day per pig for the last half."

**VEGETABLES:** I feed vegetables to the pigs raw unless they happen to be kitchen leftovers, but Stephen cooks them! "I raise vegetables for the organic market in this area and always seem to have more than I can sell of one thing or another from year to year. One year it will be extra potatoes, the next year it will be extra carrots, and every year I have small cobs of sweet corn that I wouldn't want to sell. I can't see just letting this stuff go to waste, so I feed it to the pigs. I harvest the root crops with a potato digger that was manufactured in 1888, bring them into the barn, and put them into large wooden boxes. When I have time, I scrub up some of the veggies and put them into this large cast iron pot that I bought new a couple of years ago from a local foundry for $114. I build a fire under the pot and by dinner time the veggies are cooked through. I take a pail of them out and let it cool down some. It is usually starting to get cold here about harvest time and the pigs dive right into these warm cooked veggies. The pigs are happier with their bellies stuffed full of warm cooked veggies on a cold fall day.

"Before I bought my cast iron pot, I used to bring potatoes into the house and scrub them up and put them in a kettle on the wood cookstove. I did this as the last chore of the day and they would bubble away until we went to bed. The veggies would be cold in the morning when we got up, but by the time we got the stove going and a pot of coffee down the hatch, they were nice and warm, and the pigs relished them for breakfast. This is optional for you, but the pigs, after being treated to warm veggies for breakfast a few times, made it mandatory for me!"

**FORAGE CROPS FOR PIGS:** Stephen: "Remember that it is cheaper to buy seed than it is to buy feed. I have 2 different fenced in areas for my pigs. I used to plant garden vegetables in the one that the pigs would not be in, getting the advantage of their weeding and fertilizing, until I tried planting alfalfa 1 year. If you plant a legume you will be providing your pigs with protein. Protein supplements are the most expensive part of your balanced ration, so if you plant some legumes you can eliminate those too. I plant alfalfa in the field that the pigs will not be in during the year that I plant it. If you have only 1 field, then forage alfalfa will not work for you. But you can still plant something for your pigs to graze on. You can plant it the same year they'll eat it. That something is rapeseed, or the name I prefer, 'canola.' (See Chapter 4) Ladino is another popular legume for pig pastures.

**Farm Equipment:** Stephen: "Now, as you might have already gathered, it is going to take a large amount of feed and bedding to make this operation go. You will also have a considerable amount of manure to spread on your land. You will need at the very least a manure spreader and something to work the land with. You can buy the feed and bedding, but that will not leave you with much profit unless you are the type of person who can manage the whole thing well.

"You can grow some feed, but you will have to buy a pig starter to insure that the little ones grow rapidly and get proper nutrition. You will have to buy some protein supplement to make sure that you feed a balanced ration, in addition to all of the things mentioned . . . above. You can grow your own corn, oats and alfalfa and thereby cut your feed costs to a minimum. I believe that is the only way to go. You will have to have enough land and the right equipment to make it work.

"As the bare minimum you will need a tractor and a disc. This is a farm tractor; not a city-type lawn-mowing tractor. You might want to get a small used grain drill, but you can get by with a hand cranked broadcast seeder. They are still available from seed catalogs and farm supply stores. You will need an Esmay seeder to plant the corn with or an old farm-type corn-planter pulled by the tractor. You will need a corn-picker or you can pick it by hand. You will need something to cut down the hay and oats with, an old hay mower or one of the new walk-behind sickle bar mowers will do. I recommend that you cut the straw by hand and buy the oats to feed the pigs, unless you can find someone to come in and combine your oats for you. It would make your life easier if you had a baler to bale the straw and hay with but it is possible to get by without it if you are able to put the time in to pick up the hay by hand."

**Crop Rotation.** "Five acres of land should be enough to make the whole thing work. This depends, of course, upon how fertile the land is. You divide the land into 5 equal plots through which you will rotate the crops. In the first, which you have worked thoroughly in the fall, you plant oats and alfalfa seed . . . as early in the spring as you can get on the land to give it one final working. In the second, you have alfalfa planted last year, which you will cut for hay, and from which you harvested oats last year. In the third, you have alfalfa, which you will pasture this year, and from which you harvested hay last year. In the fourth you plant corn. It was last year's pasture, and you worked it last fall and again in spring until it dried out some and warmed up. In the fifth you will grow root crops for the pigs and
vegetables for yourself. Last year it was corn and you worked it in fall and again in spring until it dried out and warmed up.

"This is all fine and dandy once you get the rotation going, but how do you start it? My brother worked all of the land in the fall. On one fifth he planted oats and alfalfa; on the second fifth he planted corn; on the third fifth he planted root crops and vegetables; and on the fourth fifth he pastured the pigs. The remaining fifth he worked every 10 days or so all summer long. The next year he planted oats and alfalfa on the one he worked all summer, pastured the pigs where the root crops were grown, cut the hay, planted corn where the pigs pastured, and planted root crops where the corn was the year before. Only in the first year did he have to buy extra protein supplement."

**Keeping a Sow and Raising Piglets**

Pigs are wonderful reproducers. Numerically, you could start with 1 sow and a boar. She will have 2 litters of average 10-12 piglets each year. If you keep all her female offspring, within a year her first babies will be farrowing also. And so on. Within 3 years you could have more than 700 pigs!

Keeping sows and raising little pigs is hard, harder than any other livestock breeding operation I think. Pigs can catch things pigs catch, plus practically every disease people get too. And they're most likely to get sick during the time between their birth and weaning. The first problem is birth. At least 1 out of every dozen piglets is born dead. Even professional pig raisers lose an average of one-fourth of their piglets, counting those born dead. And feeding breeders is much more expensive than feeding a weaner pig, which is butchered at 200 lb. These are much bigger animals—maybe 500 lb. for a sow, up to 1,000 lb. for a boar. One of them will eat more than 2,000 lb. of feed per year. Infertility can be a problem also. About 1 out of 10 sows doesn't get pregnant. Costs can be brought down by keeping more sows—the average commercial operation keeps more than 50—but the more pigs you keep, the greater the risk of disease.

When breeding, consciously choose the genes you want to pass on. Cull pigs with problems of body or personality. You want a boar that can do his sexual job but is tame with you. You'll keep sows that have large litters of same-sized babies (runts are born dead or have trouble making it afterwards) and whose babies grow well and stay healthy.

Stephen: "It requires more planning and investment of time and money. It is as different from raising a few feeder pigs as swimming in the local swimming hole is from swimming the English Channel. At the local swimming hole you just plunge right in and flail away. In order to be successful on a swim across the channel you need to steel yourself against the icy waters and there are logistics to be considered.

"You will enter a business in which the price is set in Chicago. You can charge what you want if you raise organic pigs, but if you can't find enough buyers that are willing to pay your price you will have to sell at the market price. If you are forced to sell at the market price you will come up against the pork factory people. They can beat your head in with their cruel brand of efficiency. Pig prices fluctuate, at times wildly. You may have to take losses, which may cause you to want to get out of the business. As soon as you get out of the business, the prices may go back up and you may want to kick yourself for getting out. This happens all across America on a regular basis. The pork factories have the capital and the information provided by the Pork Producers Association to which they subscribe, to aid them in making decisions. You will be alone. They are ahead of the game, and still from time to time even they get burned.

"You say that you will get into the pig-raising business on a small scale, and thereby be able to take the hits in the bad times and profit in the good times? But there are limits to how small you can go. My brother says you have to have at least 6 sows to make it worthwhile to keep a boar. . . . And you will also have to have an all-weather building, plenty of feed, lots of pasture—and straw bedding, which will have to be grown, and baled or chopped by you, or bought. You will have to handle tons of manure and must have a place to spread it and something to spread it with. You'll need a livestock trailer or some means to haul the pigs to market. In short, you will have to have a full pen and a thick checkbook, with the final question of profit and loss answered only in muffled tones. You will have to keep the books with a very sharp pencil over a long period of time to find out how you are doing.

"Well, I suppose if you had dreams of being a small-scale pig raiser, about now you are heading for the tissue box to dry your tears. Get a tissue . . . and then read on. There's still hope. You could raise pigs in a family herd!"

**Raising Pigs in a Family Group**: "Pigs are raised almost everywhere in the world and there are many ways to manage them. In Europe, they are still herded into the oak woods each day to fatten on the acorns that fall from the trees. In Asia, they are still kept in bamboo hutchs at night and allowed out to pasture each day. In some places in America pigs are still raised under strawstacks and in barnyards with beef cattle. . . . It is up to us to use our ingenuity to find out how to raise pigs in a fashion that we can morally live with—and with a little work and a little luck still make a profit.

"We had a neighbor who raised pigs using the strawstack method. [See Chapter 3.] He was the last one, besides us, who used a binder and a threshing machine to harvest grain. He pulled the threshing machine out into the barnyard and blew the straw into a stack over a 20 by 20 foot hutch that consisted of cedar posts dug into the ground and rough-sawn lumber nailed to the cedar posts. There was 1 door that faced to the south, and not much of a roof so that plenty of straw could fall through it onto the floor of the hutch. The pigs lived here year round, being let out onto pasture in the summer. Boars, sows, feeders, and weaners lived together under 1, sort of, roof.

"He raised corn, oats, and alfalfa for them . . . the local cheese factory . . . gladly gave him whey, some of which he fed directly to the pigs and some of which he used to wet their feed. He had 4 huge wooden barrels to which he added finely ground alfalfa, oats, corn, and whey. When 1 barrel was empty, he just filled it again with layers of more dry feed and more whey and then allowed it to sit until it began to ferment.

"I'm telling you it was pig heaven. People who wanted pigs to butcher, or feeders to raise for butchering, came from miles around to buy old Harwood's pigs. It worked, and he made money on the operation. He has since died and with him went the last of the pig raisers who used the strawstack method in this area. I mourn his passing.

"That kind of an operation must be run by a special person. Harwood got inside his pigs' heads and understood what it took to keep harmony in the community of pigs.
He weeded out the potential troublemakers before they disrupted equilibrium in the family of pigs. It sounds crazy, but he was a real life pig psychologist.

**Keeping Sows the "Modern Way":** Stephen: "For this system it takes harder work and more start-up money to have success. The hard work comes because we have to feed the pigs individually, fetch bedding for them, clean out their manure, and attend to their health. Money is necessary to build them a building, build pens in the building, build or buy farrowing facilities, grow or buy feed for them to eat—and from time to time pay the veterinarian to restore their health."

**Keeping One Sow.** Stephen: "If you are willing to go through all that to get her pregnant, you can raise a couple of batches of pigs from a single sow each year. You may raise the first batch of piglets up to butchering size for your family and sell the last batch as feeders. If you have a good sow and a little luck you could have 8 little ones each time your sow farrows. If you raise the first batch to butchering size, you can find buyers for the meat, and charge $1 a pound dressed weight; you can expect to make $1,240 on them. Add to that the 8 feeders from the second batch at $35 apiece, and you come up with a grand total of $1,520. This is, of course, before you subtract your costs. You might clear $500 a year."

**Keeping a Boar and 6 Sows.** Stephen: "If you want to keep a boar yourself, then you can get 6 sows, but you will either have to convert an existing building or build a building to house them. For this number of pigs you will have to build a building at least 20 x 30 feet. This allows for eight 4 x 8-foot pens in one room, and a nursery and feed room in the other room. The 4 x 8-foot pens are placed along the outside walls leaving a 4-foot aisle down the middle. The doors of the pens are 4 feet wide and must be made to swing out into the aisle. This is done so you can move pigs from one pen to the other as need be. The doors of the pens should have a hook on them to keep them shut and also so you can hook them to the pen across the aisle, and thereby block the aisle while moving the pigs around. The pens and doors should be made of at least inch-thick plywood or full inch-thick rough-sawn lumber. All of this has to be made very stoutly because pigs are very powerful and love to scratch themselves. Any weakly built pens will have to be smaller, it's expensive, and it's difficult to manage the pens and doors should be made of at least inch-thick plywood or full inch-thick rough-sawn lumber. All of this has to be made very stoutly because pigs are very powerful and love to scratch themselves. Any weakly built pens will have to use either a neutral pen at your place or take the sow to the neighbor's boar. If you don't have a livestock trailer you can borrow one or put the sow in a crate. If you put her in a crate you will have to lift her onto a pickup truck. She will have to stay with the boar until he has done his job. You can never be sure if she will settle and become pregnant, so you have a neighbor willing to let you use his boar."

**Heat:** Most gilts have their first heat by 9 months old. But hog breeders may wait until she is a year old or has had 3 or 4 heats before breeding because then she'll produce more babies than if bred sooner. The first heat can be hard to detect. Once started, she will be in heat every 18-24 days for 2-3 days at a time. Signs of it are swollen, reddish vulva, possible discharge from it, and restless behavior including pacing around and noises ("barking"). An especially rich and plentiful diet right before breeding helps make her yield more eggs and have more piglets.

**The Mating:** "Don't put a strange boar in your sow's pen. She will not be happy with an intruder in her home. You will have to use either a neutral pen at your place or take the sow to the neighbor's boar. If you don't have a livestock trailer you can borrow one or put the sow in a crate. If you put her in a crate you will have to lift her onto a pickup truck. She will have to stay with the boar until he has done his job. You can never be sure if she will settle and become pregnant, so you may have to repeat the process more than once."

**Mating Systems: Pen, Hand, and AI.** The boar can be in a pen with as many as 10 sows for a time to accomplish breeding (this is called "pen-mating"). But then you're not absolutely certain if the job got done. "Hand-mating" is surer. In this case you put the gilt or sow that's in heat into a pen with the boar and watch until they're done mating. Some growers give them a hand—literally—guiding the connection to target success. It's even surer if you repeat the encounter again the next day. With hand-mating you know for sure it happened and you know for sure when so you can put her due date on your calendar. The third possible system for breeding is AI. AI hasn't been as successful with pigs as with some other animals. Litters may be smaller, it's expensive, and it's difficult to manage the sow's cooperation. However, it's an option when you have no boar and a good way to introduce champion or exotic genes to your herd.
Pregnancy and Farrowing

After breeding is done, circle the calendar day 114 days away (3 months, 3 weeks, 3 days). With luck she’ll have babies then. Since there’s no way to know if she’s pregnant until she delivers, you now have to wait to find out for sure, although you can usually tell by around the 80-day-point. As she gets farther along she’ll get a larger belly and milk coming in. Failure to show heat signs suggests pregnancy but doesn’t prove it. Pregnancy usually goes well.

HOUSING FOR MOM AND PIGLETS: Your choice is a “farrowing crate” or a natural pen with plenty of straw for bedding, large enough for her to get some exercise, and to teach cleanliness, rooting, etc., to her babies. The “farrowing crate” is used by commercial producers—it’s easy to work around because of its smallness, it protects the babies from being laid down on because of its special side structure, and it makes it easy to give shots, take a temperature, and take out and work with piglets. The bad things about a farrowing crate are that mom will be unable to make the traditional nest that her instinct is urging her to make, she can’t exercise, and she can’t teach her babies anything. A major argument for the farrowing crate is that it reduces losses from “overlaying,” which is when piglets are unintentionally smashed by a reclining big mama. However, if you provide heaps and heaps of straw for her nesting instinct, she’ll make such a deep nest that a squirmy little piglet can make its way safely out from under her through all of it. In cold weather a heat lamp that offers a 70-80°F area is nice for crated babies. In a natural pen situation, a heat lamp could provide it, but the piglets are likely to ignore your efforts and instead cuddle up to Mom for warmth.

THE FARROWING COUNTDOWN

1. Right before nest building, her mammary glands (“udder”) become distended with milk. If you squeeze a teat, milk will squirt. She shows signs of nest-building. If she isn’t there already, move her to where you want her to birth and live with her babies. Wash her.
2. In the 24-48 hours before birth the mother-to-be gets restless, tries to build a nest. Provide plenty of clean straw, which she will work hard biting into small pieces and piling up.
3. Labor begins. She is breathing faster. Her temperature rises. She discharges a little mucous and blood.
4. Before 2 hours the birthing of her sequence of piglets begins. It may take 30 minutes to as long as 5 hours, depending on how many piglets there are. She’ll be delivering a piglet about every quarter hour. An average sow has 10-12 babies, usually no more than 14. A gilt in her first birthing is likely to produce fewer—maybe 6.
5. It’s good for somebody to be there. The piglet comes out with a covering of thin individual placental skin. You can wipe it clean and dry or let it dry naturally. The wiping especially helps if the membrane or mucous are around the piglet’s nose or mouth. Piglet birth survival rate is better with this human attention. Problems with the delivery itself are more likely if she’s overweight, or if a baby gets caught in the delivery route. If that happens, pull on a rubber glove, lubricate it, and reach in and help. Most sows in labor will scarcely pay attention to what you’re doing. (However, the occasional exception to that rule can be dangerous. Make her into sausage; don’t pass on that trait!)
6. After she has delivered the very last piglet, the afterbirth will come out. Get it out of there.
7. Stephen: “Standard operating procedure is to cut and treat the umbilical cord, cut out the baby teeth, give each piglet an iron shot, castrate the boar piglets, and dock the tails.” They dip the umbilical stub into a container of iodine. They may also weigh the piglet. (See below.) A shot of deworming medicine is another option for this stage. However, some family growers skip all this and have fine piglets.
8. The babies will naturally find her teats and begin to nurse. It’s important that all the babies get some of the first few days’ milk production—the colostrum.
9. A “runt” is any piglet born weighing under 2 lb. Not all the mother’s teats are equal in milk supply. Those nearest to her head give more milk. A runt or weak piglet who is always pushed back to a hind titty by more husky siblings is going to fall even farther behind in growth. In fact, 60 percent of runts die. It can help a runt to give bottle supplements, but some don’t make it anyway—or they live but remain smaller than average in size.
10. The piglets need iron or they’ll get anemia. If you have a natural pen with an outside run (real dirt), mom will soon take them out to the dirt. They’ll scamper and play there, and they’ll instinctively get their needed iron by eating dirt. Piglets raised without access to dirt have to get iron in a shot or as a feed supplement, or you can give them nice, clean dirt several times a week. Another system is to paint an iron solution on the sow’s udder—if she’ll lie still for that.

NOTE: Mother will be protective of her babies, and come worryfully running if one hollores—possibly with a dangerous attitude. Be careful! To take piglets from a pen wear heavy boots and thick gloves, and act quickly.

RAISING ORPHANED PIGLETS: If you get orphaned piggies you can raise them in the house. Spread some straw in your basement and provide some dirt in a box the same way you would for a kitty. A pig will use his litter box just the way he’s supposed to. Start out feeding the piglet with teaspoons of milk thickened with a little farina and sweetened with a little light corn syrup. Soon the baby can move on to cream of wheat and oatmeal. If your little pig isn’t doing well on this diet, or if you have a sick one, the best special diet of all for little pigs is eggs—just plain shelled eggs in a bowl—anywhere from 2 eggs on up to 7 or so. Offer them 3 times a day. If you want to bottle-feed a pig, use any quart bottle with a lamb nipple, less for a smaller pig. But a
plain milk will tend to make them sick. They really need some grain mixed in.

Margie Stroupe from Weingarten, MO, wrote: "...our mother sow had 15, came down with milk fever and almost died. She squashed nine because she couldn't handle herself and before I got nerve enough to get in with her and take the 6 living ones. Andy was down on his back and all he could do was stomp around because he was afraid she'd get me. But she couldn't even get to her feet. We called the vet and spent $15 for the sow's shot and the vet said if she wasn't better by morning to knock her in the head and put her on a brush pile. Well, his medicine did her no good and we wound up giving her 7 ccs. Combiotic [animal antibiotic] night and morning for 4 days. She got well, we fed her out, and on May 11, 1974, she butchered out 306 lb. without head, feet, skin and the like. So though we hated to do without a brood sow, she wound up feeding us almost a year. The baby pigs, well, that's another story. The milk I fed them wasn't the right formula and I lost 4 with scours [diarrhea] and getting them too hot."

But you don't want to keep pigs in the house too long. The lady who used to own this house told me how once she had an orphaned litter of 6 pigs living in the basement. One day a salesman came to call upstairs at the front door. She rushed up the stairs to let him in and forgot to shut the basement door behind her. The now-not-so-little pigs charged up behind her. The salesman saw her, and the 6 pigs charging up behind her, he looked really worried and sputtered, "Oh, I must have the wrong house," and literally ran away. You've got to be made of tough stuff to work door-to-door in the country!

A weaner-sized pig now needs other foods besides milk to be okay. Straight milk can cause them to bloat and die.

**FEED SUPPLEMENTS FOR PIGLETS:** Piglets can start eating supplementary "starter mash" at 1-2 weeks of age, but they'll never get a chance at it unless you use a creep feeder—a set-up where there's a hole to the starter mash supply big enough for piglets to "creep" through, but not big enough for mom to come and hog it—which she will if she can. Note: Commercial starter mash for piglets typically contains the antibiotic, sulfa. Pigs for slaughter fed the same thing would be condemned for sulfa residues.

**WORMS:** Whether your pigs have ever had worms or not, it's best to give worming medicine immediately upon bringing new pigs of any age to your property and every 6 weeks thereafter because pigs are so prone to worm problems. Get a bottle of liquid worm medicine from your veterinary products supplier. The exact instructions are on the bottle. You withhold food and water for 24 hours, then mix the appropriate amount of medicine with water and serve in their food through the next day. They drink it down willingly. But Barb Ingram from Santa, ID, sent me this different advice: "After bringing your new pig home, worm it. Then feed it all the slag coal it wants, and there is never any need to worm again."

Stephen gets the last word here: "Well, that is all there is to it. If this is your cup of tea, have at it. I hope to see you toiling in your own field some day. And remember, pigs are people too!"
BUTCHERING THE PIG

NOTE: Read all the relevant instructions over at least once before you begin.

Getting Ready

SEND IT OUT? Stephen hires his butchering done. “Our butcher doesn’t smoke the hams and bacon; he sends them out to somebody else. So we make 2 pickup trips, 1 to get the unsmoked meat and 1 to get the hams and bacon. Pork doesn’t have to hang for a week or so like beef, so 2 days after they butcher, the unsmoked stuff is ready to be picked up. It takes longer to make the smoked stuff, as much as 10 days to 2 weeks longer. I have the bacon cut thicker than store-bought, 7/16 of an inch. It fries up much nicer. You wind up with fewer pieces, but you have something to sink your teeth into. I like side pork, which is bacon that is not smoked. So we only have 1 side smoked and have 1 cut up fresh.”

Even this can have pitfalls. Lane Morgan says, “Years ago our next-door neighbor was loading his 3 pigs for the ride to the butcher. Two went in the truck fine; the third had other ideas. So Bill’s son, who was a state-champion high-school wrestler that year, put the hog in a headlock, and the next day they invited the whole town for lunch. What he lost in meat for the family, he certainly gained in goodwill.”

WORKING ALONE? One person working alone will need 2–3 hours to complete the slaughtering process. It will take about 1 1/2 hours to kill, scrape, and gut the pig if you have help—and about 4 hours more to cut it up. If you have only 1 person doing this you’ll want either to scald the pig by the “barrel-at-a-45°-angle-in-the-ground method,” or skin it. Best of all would be if you can work together with 1 or more neighbors at a hog-butchering bee in your area. Then you can use their facilities and learn from their experience.

HOG BUTCHERING BEE: Up at a ranch on a nearby “ridge,” which means on the land up out of our canyon (where there is gently rolling ground called “ridges”), there is a big hog-butchering bee held each fall. Last year when we went, there were 19 hogs butchered in 1 day by 10 men. The women brought food for lunch, potluck-style, and in the tool shed where we lunched there was coffee and a fire going all day for hand- and food-warming. The men who scalded and scraped and sprayed the pigs (they had a hose attachment) wore rubber raincoats, rubber waders, and woolen hats, since they couldn’t help but get wet in those freezing temperatures. (Hog butchering bees are usually held between December 9 and February 12.)

BUTCHERING AGE: Ideal pork comes from a young, healthy, meaty hog that weighs from 175 to 240 lb. In this we-love-lean era, people are leaning toward the low side rather than the high side. Heavier, fatter hogs produce proportionately less lean meat and more fat. The average hog produces as much pork as a family of 2 will eat in about a year. The meat from boars has a strong odor during cooking and an off-flavor described as being “soapy.” So males are almost impossible for 1 person to do alone and not easy for 2. A big hog won’t fit in the barrel. About 240 lb. is tops.

SKIN OR SCALD? First of all you must decide if you’re going to skin or scald your pig. I’m going to offer you a choice of 3 ways to proceed with the pig, and 3 sets of corresponding directions: First, directions for team scalding in a barrel or vat; second, directions for 1-person scalding using a barrel on the ground; and third, directions for skinning the pig. Whether you skin the pig or scald it, keep in mind that pigskin, unlike the skin of other large animals, is edible. You can package and freeze it. You can add some pigskin to boiled potatoes or to milk gravy; a piece of it can be used to flavor baked beans. Or you can cook it with the cracklings when you make lard. Or cook it in the oven to get all the grease out, then eat what’s left for a snack.

SKINNING Considerations. An inexperienced skinner is likely to lose a significant amount of lard and bacon because the bacon is right under the skin, and the skin does not strip away cleanly from the pig as it does from other animals. From a skinned pig, your bacons won’t have a rind, your hams won’t have a skin. And to skin a pig is a miserable job, especially around the head. There’s nothing worse to skin than a pig. Well, not much.

GETTING READY TO SCALD: You must have yourself all set up and ready before you kill the pig. Make sure you’ve thought of a good way to get the pig into the hot water because if you let it lie too long in cold air before getting it into the vat, the body heat starts out. Start early in the morning to heat your water. You can use snow if it’s clean. Use a good-sized scalding vat.

50-Gal. Barrel Vat. You can make do with this if it’s clean inside, but sometimes they have held insecticides; you need to know the history of the barrel. Set it up so you can heat the water in it by means of a fire under or around it. To scald in a single barrel, you have to get the pig in, then pull it out, turn it around, and then get the other end in to scald it. That’s almost impossible for 1 person to do alone and not easy for 2. A big hog won’t fit in the barrel. About 240 lb. is tops.

Permanent Vat. The best thing is to make a permanent vat. The nicest ones are made out of sheet metal. This is set up with plenty of space underneath to build a fire and with a platform on each side, made of something like old bridge
timbers, that won’t catch on fire easily. The platform is for the men to stand on while they are rolling the pig in the water. An old steam-engine boiler also makes a good vat. Ours is made from half of an old steel hot-water tank. To make a really nifty vat, you can pick up some used firebricks (or even find some for free for hauling them away). Dig out a pit and line it with the brick; place your vat over the top. Be sure to leave enough room at both ends to be able to start your fire and to add more wood to keep the water hot.

Make a hole in the lower end of your scalding vat that you can plug with a whittled cork or some such. It helps mightily if the vat is located where you can get at it with a hose line from the house or some other water outlet. Rinse water through the cavity to clean it out a little. Then put water in it. You want to have a big enough vat and enough water in it so the pig is almost covered with water. Allow for losing some water by sloshing out at the side if you are doing more than 1 pig. You can’t add more water because then it will be too cool for the next pig—unless you’re willing to wait while it heats up again.

**Test Water Temperature.** It’s handy to have a dairy thermometer to get the water’s temperature. Between 150 and 165°F is right, but from 140 to 180°F works. The old-timers say that if you dip your hand through the water 3 times and on the third pass it feels so hot you can hardly stand it—it should be just right (if your hands are cold to start with). If the water is too hot, you’ll cook the hog, and, worse yet, the hair will set and be very hard to get out.

**Add Lye to Water.** Put in about half a can of lye to 200 gal. water. Makes it clean up easier. The old-timers used a couple shovelfuls of wood ashes for their lye solution. (Stir well.)

**NOTE:** When the water is the right temperature, it’s finally time to kill the pig.

### Killing a Pig

**SHOOTING:** Make a mental X from the pig’s left ear to its right eye and from its right ear to left eye; where it crosses, shoot. It helps to wait until the pig looks at you before you shoot. Shoot straight in because the brain is small. A pistol is by far the best for this job (which is a good reason why country people don’t want their pistols taken away). Get the right angle so you’ll do the job the first time because it’s much harder to get it right if the pig is wounded and jumping around. A .22-caliber is the most economic on meat because it doesn’t destroy much and is still big enough to do the job (on a 200-lb. pig).

**Shoot here**

Patricia Kenyon, Castlewood, VA, disagrees: “Don’t use the .22-shot-to-the-imaginary-X-on-the-face technique. Instead, do not feed the hogs their evening meal. The next morning, lay out a sumptuous hog feast for them, walk up behind the happy, munching hogs, place the gun behind the nearest hog’s ear, aim toward the diagonally opposite eye and shoot the hog. A .22 does not make enough noise to spook the other hogs. The shot hog will keel over, having died in [ecstasy]. The other hogs will move into its vacated position and you can dispatch the next hog without moving. This works better than the front shot because the skull is much thinner from this angle. I developed this technique after annoying a 600-lb. hog with the .22 front shot. As the screaming hog began charging around the barn, snapping viciously, my helpers (2 farmer neighbors) shimmied up the nearest support posts in my barn and left the rest to me. After that ordeal, I went to the local college and studied the hog skeleton they had on display.”

**STICKING:** Now immediately, using a long narrow-bladed sharp knife (at least 7 inches long) cut open the hog’s throat about 3 inches in front of the end of the breastbone, then cut down inside and slightly back under the breastbone, until you get the jugular vein or the aorta. You’ll know because then the blood will pour out. If you haven’t got it just right, keep cutting until you do find it. Killing them is no fun, anyway. Do it right. The animal has to be well-bled, and the sooner it dies after you first shoot it the better for you both. For a knife you can use a large hunting knife or a good stiff butcher knife. The best place to cut is right back of the jaws in the center of the throat. Cut toward the pig’s left side to get the aorta. Now wait and let it bleed. Adjust the head so the opening is downhill from the body and so the jugular opening is not covered.

**MARKING OWNERSHIP:** If several families’ pigs are being butchered together, you cut an ear of the dead pigs to distinguish your own—1 notch for theirs and 2 for yours, for example.

**MOVING PIG TO WATER:** At the big butchering bee they have 2 tractors with fork-lifts (“farmhand,” “front-end lift,” “buckrake”) working to move the carcasses around. The carcass is rolled into the hydraulically operated fork-lift on the tractor. You then raise the fork-lift and let the tractor take the hog to the scalding platform. If you don’t have a fork-lift, the next easiest method is to use an old-time hay hook. Insert the hook point in through the open mouth, then out through the jaw so that it will be pulling against the strong jawbone. Drag the animal by the hook over to your scalding vat.

### Scalding a Pig

**USING ROPES:** Lay the pig on the platform by the scalding vat. You now need two 30-foot (more or less) ropes. Half-inch rope is fine. You can make do with 1, but 2 are much better. Smaller rope is harder to get hold of and to work with.

Rope the pig up before you put it into the vat. With 1 rope this is a 2-man job. (With 2 ropes you use 4 people to roll the pig.)

1. Make each rope have a U shape.
2. Lay the pig on ropes across the U shape.
3. Bring the 2 free ends of the U over the pig and through the inside of the U.
4. Now take those free U ends back to where they were.
Knowing When It's Ready. If the hair is worn off where the ropes are around the pig, it's getting pretty close to being ready to come out. It will take 3–6 minutes of scalding to loosen the hair and scurf. The most difficult time of year to get the hair loosened is in the fall when the winter hair is beginning to grow. (That time of year you might benefit from higher water temperatures or longer submergence times.) If you can grab a handful of hair and the scarfskin comes off with it, it's ready. Or better yet, take a hog scraper, or a knife, and just scrape on part of it that's starting to come out from the water while it's still in the vat. If the hair comes off, well, it's ready. If the dewclaws will snap off, the hair is slipping, then it's ready to scrape. Now haul the pig out. If this is a 2-man job, hand over both rope ends to 1 side so that both can haul the pig out from that side.

Scraping the Body. After you're done with feet and head, do the rest. When you get one side of the pig done, roll it over and do the other side.

Hog scraper

Read about scraping, above, before proceeding.

You'll need about 50 gal. of near-boiling water. Once you get the water into your scalding barrel, you can adjust to the more exact temperature (between 140 and 145°F, recommended) by adding cold water. If you have 2 barrels, you can use 1, with a fire under it, for heating your water. You can have another one buried in the ground almost to its lip at about a 45° angle. Having the barrel buried makes it humanly possible without any other machinery or

Extra Hot Water. Scrape your pig right by the barrel or the vat so that you can get hot water for pouring over it. Plan to have hot water to spare, because it helps, especially when scraping older hogs (which get really tough to scrape, especially red-haired ones). The last resort, if scraping doesn't work, is to pour more hot water over them out of a bucket, then pull hair out as if you were pulling chicken feathers.

Scraping Method. As you scrape you get not only hair, but also dirt and the scarfskin. Scoop more water up in your bucket and pour over to keep the pores hot and soft so the hair will keep coming loose. Try not to cut through the hide. Work over the whole body this way. The best scraping motion with a knife is to hold the knife on both ends. Don't pull the way you would slice; that cuts the skin. Pull across (sideways). Scrape the hot carcass as quickly as possible, because the hair tends to "set" as it cools. If you come to a patch of hair that is difficult to scrape because it didn't scald enough (like the mid-section of the pig), cover it with a burlap bag and pour hot water over it until loosens up. It will also help with the scraping if you place the legs or head so as to stretch the skin and smooth out the wrinkles.

Scraping the Feet. The feet are hardest to scrape. If you are planning to save the pig's feet for pickling or some such, do them first, while they're hot. You can pull the toe nails and dewclaws from the front feet by inserting a hook into the top of the nail and pulling. Do the same with the rear legs. Grip the legs with both hands and twist to pull off the hair. Leave the feet on for the time being. You can use the scraper on the rest of the carcass.

Scraping the Head. Do the head around the eyes, nose, and jaw next after the feet. On an old hog there will be bristles on the snout (whiskers). You can shave them off with a sharp knife, barber-style, or singe off as you would a chicken. More than 25 percent of your scraping time will be spent working on the head because it's hard to get around the parts of it. Save the ears. They are good to flavor meat in the jowl (cheeks) that will make good scrapple, headcheese, salt pork, or side meat. Most people leave on the ears.

Scraping the Body. After you're done with feet and head, do the rest. When you get one side of the pig done, roll it over and do the other side.

One-Man Scalding System: This method is from a USDA booklet, "Pork: Slaughtering, Cutting, Preserving, and Cooking on the Farm" (Farmers' Bulletin Number 2265).
Skinning a Pig

The skinning procedure used for a pork carcass is similar to that used for beef carcasses. Skinning requires less equipment and can be done faster than scalding and scraping. To begin, place the carcass on a clean surface (plywood, concrete, straw); wash any blood and dirt off, turn the carcass on its back, and hold it in place with blocks placed on each side. Cut the hide around the rear legs, just below the dewclaws. Make a cut through only the hide, down the back of the leg, over the hocks, and to the midline at the center of the hams. Skin around each side of the leg, removing the hide to a point below the hock. Open the hide down the midline from the point where the animal was stuck in the neck, around each side of the pubic area and continue to the anus. Make this cut by inserting the point of the knife under the skin with the blade turned up. This procedure is a sort of cutting from inside out and will, you hope, protect against puncturing the intestines.

Remove the hide from the insides of the hams. Be careful. It is very easy to cut through the fat into the lean. Continue skinning along the sides toward the breast. Grasp the loosened hide in the opposite hand and pull it up and out. This places tension on the hide, removes wrinkles, and allows the knife to glide smoothly. Holding the knife firmly, place it against the hide with the blade turned slightly outward. Skin as far down the sides as possible, but not around the front legs. Return to the rear of the carcass and remove the hide left on the rear of the hams. Do not skin the outside of the hams at this time. Remove the rear feet by sawing through the bone about 2 inches above the hock. Insert the spreader (see "Hanging a Pig") under the large tendons on the rear legs and secure the legs to the spreader.

Hoist the carcass to a convenient working height for skin removal from the outside of the hams. Skin around the outside of the hams, leaving as much fat as possible on the carcass. Remove the hide around the anus, and cut through the tail at the joint closest to the body. Pull the hide down over the hips. The hide along the hips and back can be pulled off, leaving the fat on the carcass. Occasionally, you may need to use a knife to cut between the skin and the fat if large pieces of fat are being pulled off. Hoist the carcass to a fully extended position. Open the hide down the rear of the forelegs. Skin along the inside of the forelegs and neck. Skin along the outside of the shoulders and jowls to a point approximately halfway to the back of the carcass. Slowly pull out and down on the hide, removing it along the back. If the fat begins to tear, use a knife to correct the torn area, and then continue pulling the hide. Remove the hide as far down the back as possible. When it becomes difficult to pull along the top of the neck, complete removal with a knife. If the head is to be saved, skin over the poll and down the face. Remove the hide at the snout. Remove the front feet by sawing just below the knee joint.

Skip "Hanging" because you've already done that, and continue with "Gutting."

Hanging a Pig

After scraping, it's time to hang the pig up in order to gut it. (Of course, if you skinned it, it's already up.)

**Gambrel, "Singletree," or "Spreader":** This is what you hang the pig by. It can be any straight stick. Metal ones usually have metal hooks at each end. Wooden ones have a carved notch there. If you are making your own out of wood, basically all you need is a long enough, strong enough stick with a V-shaped notch on the topside near each end so the hamstrings won't slip off the end to the middle. A "singletree" is actually a piece of old-time horse harness that people found out made a great gambrel. Nobody around here knows what the word gambrel means. They all use a singletree and call it a singletree. We've used a neck yoke, too, and wired the legs onto it. One of these is an excellent investment if you are going to do home butchering of anything larger than a chicken or rabbit. The gambrel has to be long enough to spread the hind legs real tight, hence the other name of "spreader." For the average hog, that is about 30 inches.

**Wire, Rope, or Chain:** You need something to hang the gambrel by. Use a wire, or rope, or chain around the center to hang it to your fork-lift, or to a tree limb, or a tripod, or a rafter beam when time comes to gut the animal after scalding. If you buy a ready-made gambrel, it will come equipped with something, usually a chain or rope, in the middle to hang it by.

**Gutting the Hamstrings:** The best system is to hang an animal by the hamstrings, or "Achilles tendons." They are located in the back of the hind legs. Make a vertical slit. Don't cut crosswise! There are actually 2 cords there. Get both of them, especially on a heavy hog. Use your singletree (gambrel) to hang the pig by the hamstrings. Put 1 hook from each end of the gambrel under each hamstring. If you are using just a stick, put each end of it through the space between the hamstrings and the bone.

After the pig is hung, now is your chance to put the final touches on your scraping job. Pour more hot water over where it is needed. Scrape up.

Gutting the Pig

When you butcher a pig you discard about 20 percent of its weight. This is the stage at which most of that goes. Have some twine ready or heavy string.

These instructions assume that the pig is hanging from its hind feet and that you are standing, facing the belly side of it.

It makes a difference in method whether you are butchering a male pig or a female.

**A Male:** Cut around the penis, which is in the middle of the pig's belly, and slip the knife on up to around the rectum. Notice a cord running from the penis right under the skin up to the rectum. That cord runs right into the gut. Pick up the penis area and tie off the cord that connects to it with your twine. Cut the cord on out. Cut all around the anus to free the end of the gut and tie that. That's to prevent what's inside that part of the gut, which is not nice, from coming out on your meat at any stage of your work. When you cut around it, keep your knife sloping toward the meat and away from the anus so you don't cut the gut.
A FEMALE: Start by cutting around the anus so you can get hold of the end of the gut and tie that off with twine the same as for a male.

NEXT, ON EITHER SEX
1. Cut down the belly midline until you have the skin parted from up at the top to the jaw at the bottom. Be careful not to cut into an intestine.
2. Split the brisket or breastbone. Hammer on your knife to drive it through. The brisket is right in the center between the shoulder where the ribs join together in front of the heart, lungs, and liver. You're aiming to cut that pig into 2 separate and distinct halves, and the brisket (“breastbone”) is the hard part in the front chest that you must cut through to accomplish that.

3. Cut between the hind legs starting on the midline.
4. Finish cutting on the belly by putting your hand inside, being careful that your hand is between the knife and the intestines. Believe it or not, it would be better to cut yourself than accidentally to cut the intestines, but you won’t. Now bring the innards out of the hog, starting from the top. Have a big wash basin ready for the organs that you want to save: heart and liver.
5. Cut the diaphragm to bring out the rest of the organs. The diaphragm is a muscle layer separating the intestines area from the heart-lungs area.
6. Now deal with the organ meats: Trim off the top of the heart. Heart, trimmed, goes into a dishpan. Remove the gallbladder from the liver. If you are going to cut, then cut through the liver, if you accidentally cut into the gallbladder the bile escaping will ruin your meat. Old-timers just peel it out and they follow the duct up a ways and peel that out, too. The sweetbread looks like brains. It is attached between the stomach and liver. Leave the kidneys in until you cut up the meat. The long narrow liver-looking thing is the spleen, and it isn’t used.

7. On a large, old, well-fATTened hog the entrails will carry several pounds of fat, which you save for lard. Young hogs don’t have enough to fool with. The “leaf lard” is inside the body cavity from midline to rear on each side. Peel it out. Don’t leave it on the bacon because it’s just pure lard.
8. When you’re going to use the head, make sure that the cut is made clear down to the jaw. Then, when the innards fall out, you can pull out the whole mess from the neck, too—including the trachea, esophagus, jugular, and tongue. The last to come out will be the tongue as you bring out the windpipe and esophagus. Get the tongue out whether you plan to eat it or not, because if you don’t, blood will collect there.
9. You have to cut the head off before you can make halves. Use the biggest, sharpest knife you have. Cut the head off about an inch behind the ears: Cut the meat down until you have exposed the bone all the way around the neck. Grab the head firmly and twist it around and around until it just snaps off from the body.
10. Make halves by sawing with a meat saw right down through the middle of the backbone from top to bottom.

11. Now let the meat hang to cool. Don’t cut it up while it is warm, but pork, unlike beef or goat, is not aged. By the next day you could—and probably should—proceed to cut it up. It is not harmed though by a reasonable wait—even as long as 1 week if you have really cold weather. But it doesn’t keep as well as beef.

Preparing Suckling and Barbecue Pigs

**Suckling Pig:** This is in case you have an extra piglet. By waiting 5 months you could have all the meat of a big pig, but your sow may have had too many babies to nurse manageably. You could bottle-feed the extra, or you could kill, scald, scrape, and gut it on the same principles as a larger animal. After cleaning out the innards, rinse the pig in warm soda water. Leave on the head, but clean the passages of the head and throat with a wooden skewer wrapped in a small piece of soft cloth.

**Cooking a Suckling Pig.** Fill with stuffing. To stuff a 12-lb. suckling you might use 3 c. diced celery, 2 c. chopped onion, \( \frac{1}{2} \) c. minced parsley—all fried in plenty of butter and then combined with about 7 c. dry bread crumbs. Sew and truss. Bend the forefeet backward from the knee and the hind legs forward. Make deep cuts in the skin in 3 places. Put a potato or apple in the mouth to hold it open. Roast at 350°F until the meat thermometer reaches 185°F (3–4 hours).

**Spit-Barbecued Pig:** This works best with a smallish pig, like about 40 lb. That will feed a huge family reunion or some similarly large group. Give it a good scraping, clean it, and scrape inside and out under running water an extra time. Optional: make a dressing to stuff it (about 2 gal.). Wrap feet and ears in foil to keep them from burning, and keep the pig turning on the spit. A motorized spit is the easiest. The roasting will take 5 hours for the 40-lb. pig, more if it is bigger. Use a meat thermometer to check on how done the pig is, deep inside.

Now back to handling the 200-pounder. This one definitely must be cut up.

**Cutting Up the Pig**

Before freezers, the pig’s fat was rendered into lard, with cracklings used as a people snack or animal feed; as much as possible was eaten fresh, and the rest was heavily salted for preservation. When saltpeter came along, what had been salted meat was shifted to “cured” (“corned” if it was beef) and the amount of salt and spices could be lessened. Now that we know more about saltpeter (all bad) and have freezing and canning options, the healthiest choice for your family is obviously to freeze all of the pig, or to make sausage (which will be frozen) of part or all of it—especially if it’s a predictably tough old animal. By not curing what could have been cured for hams you’ll have roasts, and what would have been cured for bacon is “side pork,” which you can slice and fry much like bacon.

Some people start cutting it up while it is still hanging, but we bring the carcass in, a half at a time, and lay it on our big plywood cutting board, which is scrubbed in the tub with a scrub brush and then laid across the kitchen table. A pig is actually easy to cut up. I’ll theoretically divide it into thirds. The front third is figured as if the head were still on.

**Have Containers Ready:** I use 4- and 5-gal. plastic buckets. One holds meat to be cured if curing is planned. Another holds pieces that are to be ground for sausage. Another holds bones for making gelatin, or to cook up with sauerkraut or beans. And one holds fat that will be rendered into lard. I also have ready meat-type wrapping paper and freezer tape with which to wrap the roasts, chops, and ribs that will go directly into the freezer after being cut.

**First, Trim:** Trim off the dirty and bloodshot spots—everything that doesn’t look like what you would want to eat.

**The Head:** There are numerous good ways to use the meat of the pig’s head. They all require similar preparatory steps. Options:

- Prepare it according to the directions under “Headcheese and Scrapple.”
• Or cut off the jowl, which is the chin area, and make it into bacon, with the trimmings going into the sausage bucket (you want your bacon slab fairly neat-looking). Save the ears, too, to flavor a mess of beans, and you can discard the rest.

\[
\text{Jowl}
\]

• Or cut off all the meat you can get at and put into your sausage bucket—and discard the rest.

• Or cut off all the meat you can get at and use it to make pork mincemeat.

• Or cut off all the meat you can get at in thin slices, package, and freeze. You can fry the sliced scraps like side meat.

• Or clean out the ears, nose, and mouth passages well with a cloth on a stick or just a cloth on your finger and rinse well with water. Then, in a big kettle (I use my canner), cook the whole head for hours and hours and hours until the meat falls off the bones. Then remove the bones and the more strange-looking stuff like eyes and the lining of the mouth. Skim off every bit of the grease you can get to go with your lard renderings. Divide, package, and freeze what's left to go with kraut or beans. That is my favorite way of preparing the head.

THE HIND THIRD: This means one of the back legs.

NOTE: Instructions such as "front," "back," etc., are generally given as if the animal were standing up.

1. If you haven't done so already, saw off the hind foot through the ankle (hock) about a foot up from the hoof. You can either set aside the foot to make pickled pigs feet, or trim off the meat for sausage and put the rest into the gelatin bucket.

2. Now cut the hind leg (ham) away from the body. You'll have the tail end of the backbone included in your piece, which you can trim out later to make your ham look nice. You're cutting in front of the pig's hip bone and getting off all the hind leg with this cut. Cut the meaty areas with a knife. Finish going through the bone with a meat saw. On a sow you'll have 2 teats included plus about 2 inches. In person talk we'd call it the pig's thigh. On a young pig it will weigh about 20 lb.; on an old sow it will weigh about 30 lb.

3. Trim it around the top to make it look neat. Make sausage or lard of the trimmings (depending on whether they are meat and fat, or mostly fat). Sausage trimmings are generally cut into approximately 1-inch strips to go through the grinder better. If you are planning to cure the ham, the skin is generally left on. Put the ham into your curing bucket. If, instead of curing it, you want it to be pork roasts, trim the skin off (and place the skin into your sausage bucket). Cut the ham into roast-sized pieces; the only rigid rule is that a roast has to be small enough to fit into your pan with the lid on. Other than that, a chunk of meat is a chunk of meat no matter what the experts say. Incidentally, if you plan to cure your hams and bacons with the skin on and you have a propane torch, you can use it to burn any remaining hairs off them.

THE FRONT THIRD: These directions are meant for a young pig, the 200-lb. kind. If you are butchering an old hog, then you take the whole front third and cut up most of the meat to go through your grinder for sausage.

1. If you haven't done so already, cut off the foot at the ankle—about 8 inches above the hoof. Put it in the same place you did the hind foot.

2. Now cut off the leg plus the front shoulder. You'll find the right spot by cutting behind the third rib. You'll need your meat saw. You're cutting it off just back of the shoulder blade, straight up and down the body. If you are making hams to be cured, take the big piece that you cut off (minus the foot) and divide it in half horizontally to the ground just below the lower edge of the shoulder blade. The resulting half that has backbone in it is called the Boston butt ham or shoulder roast and the lower half is called the picnic ham. If you would rather make roasts than hams out of your Boston butt and picnic hams, again cut them down into roast-sized pieces.

3. Now trim out the backbone. Trim off the meat left around the backbone for sausage and put the backbone itself into your gelatin pile or bones pile.

4. The 3 front ribs that get included in the cut can be packaged for short ribs. Saw them away from the rest.

5. That flap of meat attached to the lower half of the front leg is bacon or sausage (or side meat if you'd rather). For bacon, cut away and make the edges nice. For sausage, cut it into strips. For side meat, leave plain and don't cure.

THE MIDDLE THIRD: That's what's left.

Separate the ribs from the bacon. You can see where the ribs are. The bacon is the boneless flap of "skin" behind the ribs. Stay out of the thick meaty pork-chop area along the backbone. You can peel the meat off the outside of the ribs, too, and make bacon out of it. Or leave it on for very meaty spareribs. That's what I like to do.
The “Bacon” or “Side Pork.” You can take the skin off the bacon or not. (Personally, I like the skin off.) If you plan to cut the skin off, whack the whole bacon section on the table as hard as you can, skin side down, several times before you start makes it a little easier. I like the bacon cut into squarish sections about 6 inches on the side. You can make them bigger—it doesn't matter. Put the trimmings into the sausage pile. I've made triangular bacon, but it slices up more nicely if it is square. Side pork is the same cut not cured; you can slice and fry it just the same for breakfast only it won't have the cured taste. Slice like bacon only thicker, season, and fry. Don't flour. Cook through.

The “Fatback.” This is the fat on the back of the pig, which you trim off with the skin for your lard pail, leaving only just the amount you like on your pork chops—1/4–1/2 inch is plenty.

Chops. What's left looks like backbone. It includes the muscles that run right alongside of the backbone. You can either bone the chops out and have them with no bone, or saw them out and have a chunk of bone included with each one. I don't like bones out of chops, though that is easier to do. Boned-out chops don't look like chops anymore to me, and, though you only lose a little meat in the boning out process, on a chop that's a noticeable loss.

To bone them out: Cut the muscle away from the bone. Slice across the grain and package for the freezer in meal-sized numbers. The little muscle on the other side of the bone can be pulled out and cut across the grain into “tips,” which means a mini-chop. The vertebrae can go into your bones department—the best thing I know for making gelatin.

To saw them out: The butcher does it with a power saw, which makes it easier for him, but you can do it by cutting the meat part with a knife and then finishing with a meat saw. Cut across the grain of the tenderloin the same way you would for boned-out chops.

The rear third of the “backbone” can be sawed into pork steaks (cut across the grain) or cut into a couple of sirloin roasts.

Headcheese and Scrapple

Headcheese is a homemade luncheon meat. It's quick and easy compared to scrapple. It's an all-meat product. You can add in the pig's tongue, skin, heart, and other scraps, if you want to. Headcheese makes a fine cold snack when cut in 1/4–1/2 inch is plenty. That takes at least several hours in a chilly place. Then you can turn it out of the pan, slice off some, and fry as described earlier.

Now that you've decided whether you're going to make headcheese or scrapple, there's the problem of what you're going to make it out of. If you have, or are going to have, a hog's head, that's fine. Some farmers don't want to bother with their hogs' heads and will sell them to you. Heads vary considerably in size depending on how old the animal was. An old brood sow can have a head almost twice as big as that of a pig of the more usual butchering age. If you don't have a hog's head, you can actually make headcheese or scrapple out of any pork-sausage-type scraps.

1. The head should be already scalded, scraped, and separated. But if the head fate has given you to work with is a still-hairy one, then you'll have to skin it—which is an awful, tedious, frustrating job, and you have my sympathy. Or you can try singeing the hairs off with a blow torch.

2. Take the head out to your chopping block and split it in half with the ax. If it looks like mincemeat before you finally manage to get the halves separated don't despair—that won't hurt the final product. Just collect the pieces off the chopping block and carry them back to the kitchen.

3. Remove and discard the eyes, nasal passages, teeth, jaw, and eardrums. You can use the ears, lips, and snout if they are well-cleaned. Scrape the ears to get them clean. Usually the jowl isn't used because it's so fatty. The “jowl” is the neck-cheek area. Remove all the fat you can and save it to render for cooking lard or soap. Make deep cuts in the thick meat pieces.

4. Put the meat into your kettle. A cast-iron kettle is best because it heats most evenly (so is an old-fashioned wood or coal burning range for the same reason). For 1 hog's head you'll need the equivalent of a canner or big 8-qt. pressure cooker to make this recipe. Cover the meat with water and simmer until it is ready to fall off the bones.

5. Remove the meat from the broth. Pick it over and separate the meat from the most of the fat, from all of the bones, and from the broth. Grind the meat.

Up to this point the recipe is the same whether you are making headcheese or scrapple. Now it differs.

A Scrapple Recipe. Skim every bit of fat from the broth. Add to the broth one 2-lb. 10-oz. box of old-fashioned oatmeal. Don't use the instant kind since it won't make good scrapple for some reason. Or add enough cornmeal to make a soft mush. Or add half cornmeal and half buckwheat flour to make a soft mush. I prefer the oatmeal but you can vary the specific grain combination to suit yourself. If you are working with a large quantity of meat, rather than just 1 head, figure 1 part dry cereal and 3 parts soup to 7 parts ground cooked meat. If you use cornmeal, cool some of the broth and moisten the cornmeal with it before adding to prevent lumps.

Now season the scrapple. For the basic 1 pig's head and 1 box oatmeal recipe, add 1/2 T. ground pepper and 2 T. salt, or vary the seasonings to suit yourself. Marjoram, sage, nutmeg, mace, and onions are all good in it. (If you use onions, grind them first and add at the beginning of the time the cereal will cook.) After your scrapple is thickened and seasoned, it has to be cooked about half an hour very
slowly. Don't let it burn on the bottom. When it is done, pour it into chilled, wet leaf-type (or other shallow) pans. That's all there is to it.

Scrapple makes a good quick breakfast or lunch. You can cut it into sections sized appropriately for 1 meal for your family, package it in a plastic bag, and freeze. To serve the scrapple, thaw it, and cut it into ½-inch slices. Some people like it dipped in egg or in egg and crumbs before frying. Fry it like cornmeal mush in a lightly buttered pan, about 10 minutes per side, over medium to low heat until browned on each side and crisp. Serve with maple syrup.

**Scrapple Without a Pig's Head.** From Ellen Curran of Douglas, OR: "Start with 1 lb. pork sausage, browned in a skillet with 1 large onion, chopped. Add 3 c. boiling water and 3 c. oatmeal. Salt and pepper to taste. Cook, stirring, until oatmeal has absorbed the water and tastes cooked. Our family eats as is, or it can be packed in a loaf pan, refrigerated and then sliced and fried in butter for breakfast. Makes a great first breakfast to take on camping trips."

**Headecheese:** Mix the ground meat mass with seasonings to taste: salt, pepper, red pepper, ground cloves, coriander, and sweet marjoram all are possibilities. Take a little sample, spice it, and then taste it to see if you like your combination. Keep testing until you get it right, and then spice the whole mass accordingly. Red pepper is good in it if you have a cast-iron stomach. I grind my own, but if you do too be sure you get it fine because if somebody bites into a speck-sized bit of it, it’ll take the top of his head off.

Pack the seasoned headcheese tightly in a bowl or loaf pan and press into as compact a mass as you can in the bottom of the bowl. For extra firmness, cover it with a weighted plate. Refrigerate. When it is very firm it is ready to slice and eat.

Still another way to use the pig's head is a combination of headcheese and panhas. Go ahead and make your headcheese. After making headcheese you have a soup broth left of headcheese and panhas. Go ahead and make your headcheese:

**Headcheese Sausage.** This is a variation you can try sometime. After the headcheese is seasoned to taste, stuff it into casings instead of pressing it into a bowl. Then recook the sausages in the pork soup until they float, 10–30 minutes. After they float, chill them in cold water. Store in a cool place. You can add a smoke flavor by giving them 4 hours in the smokehouse.

**Sylta Headcheese.** From the Johnsons of Wheaton, IL: "This serves 20 to 25. Use ½ hog's head (5 lb.), 2 lb. lean pork and 2½ lb. veal shoulder. Clean and singe off hair and bristles. Clean teeth with a stiff brush and cut off ears. Soak in cold water for 6 to 12 hours, changing water. Place meat and hocks in boiling water to which has been added 4 t. salt, 30 peppercorns, and 20 whole allspice. Simmer 2 to 3 hours, or until tender. Remove meat from broth, save broth, and cut meat in slices. Spread cloth or towel, wrung out in hot water, in a deep bowl. Line with cooked rind from pork hocks, rind side down. To sliced meat, add 3 to 4 T. crushed whole allspice (measure after crushing with rolling pin). Add 3 to 4 T. salt. Arrange in cloth. Cover with rind if any is available. Pull cloth together tightly and tie with string. Put back in broth. Cook slowly 5 to 10 minutes. Lift out so it doesn't stick to the bottom. Remove to a platter, cover with a board and put weight on for 24 hours. Set in a cool place. Remove cloth after that time and wrap in a fresh cloth that has been soaked in salted water. Put in a plastic bag and refrigerate. Serve slice thin with pickled beets."

**Chitlins**

This is the small intestine of the pig. Some people think these are the best part. Others think they're too much work to clean, slippery, fragile, and bad smelling. Pull all the fat off, rinse, and scrape as to make sausage casings until they're really clean. Then boil until tender with salt, pepper, and a potato. Serve chitlins hot with cabbage slaw or potato salad.

**Making Lard**

White, creamy lard comes from high-quality pig fat that was trimmed and rendered fairly soon after the butchering. The fats that you got from around the internal organs of the pig are called the "caul" and "ruffle" fats. If they were washed promptly, and if none of the contents of the inners were spilled on them, they can also be made into lard, except their lard is a darker color. Besides your own butchering, you could probably get fat from a butcher shop for a cheap price, if you want it; just leave word that you are interested in buying. (They'll probably give it to you.) But it wouldn't be residue-free. It's best to render lard during cool weather. Work with about 1½ lb. or so at a time.

I render our lard in a big pan in the oven. It takes more than 24 hours of slow heat. The grease will separate more easily from the tissue fibers if the fat is cut into pieces before putting it in your kettle. Some people even grind it through a meat chopper using a 2- or 3-blade knife and plate with a hole ¼ inch or larger. But that ruins your chance for cracklings.

**Cracklings:** These are the little pieces of meat tissue that are left after you melt out the lard, like frying bacon. Some people like cracklings and some don't. They are packaged commercially and sold as a snack called “pork rinds.” I remember vividly as a little girl my father's hog butchering and lard rendering and how good those fresh cracklings tasted. My husband loves them, too. If you want proper cracklings, cut your lard into strips. I do that when I'm getting ready to render the lard. I cut the fat and skin into strips—any sort of shape but I try to get them not more than ½ inch wide.

**The Heating:** You can put pure fat in the kettle or else start out with a little water in the bottom. An iron kettle is fine. Burning is a problem. *Use only low to moderate heat.* It's safest to render with that kettle in the oven rather than on a burner. Or on the back of a wood cook stove, because there is such a gentle even heat back there. If you don't get done the first day, just let it set overnight and continue on the next day when you get the stove going again. *Don't stick your face in the kettle for a close examination.* There is an occasional "pop" as some moisture in the fat turns to steam, and you might get a grease burn in the eye. Remember the stuff is pure hot grease. *Make sure the pan is at the back of the stove and that the children stay away.*

Do not fill the kettle to the top so that there won't be any danger of it boiling over. Add ½ t. baking soda to the fat when rendering is begun, which will darken the cracklings but whiten the lard. Be careful not to scorch.
It happens so easily. The fat should be stirred frequently and cooking should be very slow until the fat begins to melt and the mass can be stirred easily in the kettle. If you have a dairy thermometer you can watch the temperature.

Early in the process of rendering, the temperature of the fat will be 212°F. As the water contained in the fat tissue evaporates, the temperature will rise slowly until it reaches 245–255°F—the highest it should be allowed to go.

**Microwave Rendering.** Lois Rumrill, Forks of Salmon, CA, wrote: “A microwave oven works just super for rendering fat of any kind. Use a 2-qt. Pyrex, Corning Ware, or other glass pan. Fill pan about two-thirds to three-quarters full of fat. Cover and place in microwave oven. Set time for 12 minutes. When time is up, remove pan from oven. Pour hot lard into jars. I put a doubled piece of cheesecloth over top of jar and secure it with a rubber band. Then you can pour it out struggling on to the bitter and potentially scorched end, but at least you made it for a while. Then remove the potato.

**WHITENING LARD:** For the whitest homemade lard you can possibly make, add a raw potato in the bucket and stir it for a while. Then remove the potato.

**STRAINING LARD:** When your lard liquid is cooled down to only warm, it is ready to be put through a lard press, if you have one. They were common among the old-timers. I don’t have one and don’t know where you or I could find one except maybe as an expensive antique. I spread cloth in a wire sieve and strain through that into a bucket, and from the bucket I pour into the containers.

When you get near the bottom of your rendering pan, the sediment gets thicker. You should stop and switch cloths, this time adding a couple extra layers. Then you can pour it all out and squeeze heartily to get every last drop.

**COOKING LARD:** When your lard is ready to store, get it cooled down as soon as you can. It should be protected from light, air, and moisture. So if you are storing plain, put your lids on as tightly as if you were sealing them. If your containers are glass, store them on shelves in a dark cellar or inside brown paper bags.

**CRACKLING CORN BREAD** Mix together 2 c. corn meal, 1 c. flour, 1 t. soda, and ½ t. salt. Add enough buttermilk to get a heavy gravy consistency. Fold in 1⅓ c. chopped cracklings. (Make sure that cracklings are broken into small pieces; you can make them more tender by soaking them in hot water then draining them.) Bake at 350°F until brown.

From Donna Joehn, Blaine, WA: “Cracklings are my very favorite breakfast accompaniment with eggs. Cracklings are not the skin or rind. They are what is left after rendering out ground-up lard. They are crumbly looking things—like coarse graham cracker crumbs. To eat, you reheat ‘till bubbly and crisp, then press dry of fat in a potato ricer or with a spoon in a strainer. Salt, pepper, and enjoy in place of bacon. They sell them in British Columbia grocery stores; we live near the border where there is a large Mennonite settlement and people speak ‘low German’ on the streets.”
LARD WITHOUT SKIMMING: If you want your lard to keep just as it is—without canning or freezing it—then continue rendering, stirring occasionally to make sure no sediment is scorching on the kettle bottom. In this case it is important that all the water be evaporated unless you skim your lard off, which is a disagreeable job. When the cracklings are a deep golden brown the lard should be done. You can test for moisture by placing a lid on the kettle to see if moisture will accumulate on it. Remove from heat and let the sediment get quiet.

ABOUT RANCID LARD: Rancid lard should be discarded. It tastes bad and isn't good for you. But rancid lard does make fine soap.

HOW TO AVOID RANCIDITY: Air and light cause the chemical changes that lead to rancidity. You can improve the storage life of lard thus by keeping it in the dark and in air-tight packaging. And/or you can add a commercial antioxidant (check with your local locker plant). Adding hydrogenated vegetable shortening to lard while it is cooling also helps preserve it. One part vegetable shortening to 16 parts lard is about right.

CONTAINERS FOR LARD: Get ready your containers in which to pour the rendered lard. Clean gallon tin cans are good, even if you don't have lids, or widemouthed jars, especially half-gallons and gallons. Or the tall juice-type cans. Chill it quickly (to get a fine-grained lard) and store immediately in the coolest place you have. Seal tightly and keep in the dark.

FREEZING LARD: Water in the lard doesn't matter if you're going to freeze or can it. I freeze it. It would probably keep okay outside the freezer, but I'm a shade surer that way. I take out 1 can at a time, and it lives on a shelf beside the kitchen stove until I've emptied it and am ready for another. Store lard in a dark cool place or in a freezer, inside a metal container or in a grease-proof freezer carton, sealed with a tight cover. I dip the melted lard off the top into bowls with my cream dipper and then put it into the refrigerator to chill. After the lard gets hard, I cut it into sections and put each one into a plastic bag and into the freezer. Or else, if I have enough coffee cans, I chill it in coffee cans. Then I put a plastic bag over the top of them for a lid and put can and all in the freezer. You can freeze lard wrapped just in freezer paper if you can get it solid enough to wrap first. Cool it, for example, in a big metal bucket. Then cut and repackage in double layers of freezer paper or white butcher paper and freeze until wanted. It takes a lot of containers to store the lard from even one pig so be prepared.

USING LARD: A certain amount of lard is really very handy. You almost have to have lard to make pie crusts and good soap. You can use lard almost any place you would use oil once you get used to it. And if your animal was born to a residue-free mother and raised on all residue-free food, then you have fat that is pesticide-free and fairly low in cholesterol, and it makes a fine frying grease and baking fat. The only type of recipe I don't like to use lard as the fat in is salad dressings—except I like lard for wilted lettuce dressing. It's handy to keep most of it in the freezer, plus 1 large container in the refrigerator, and a small one by the stove, which you refill from the one in the refrigerator as needed.

LARD SUBSTITUTIONS: When substituting pure lard for "shortening" in baking, add an extra ½ c. flour for every ½ c. lard used because lard is "shorter" and needs more flour to take it up.

Deep-Fat Frying. Cheap homemade lard makes deep-fat frying a reasonable way to prepare some foods. Deep-fat fried foods are a favorite item with my family. My standard recipe is to batter whatever I deep-fry with beaten egg and flour and then fry it in grease hot enough to smoke. If the grease is hot enough before you start frying, the batter casing will immediately seal up and the food won't absorb excessive grease. It's frying at too low a temperature that results in greasy foods. See "Deep-Fat Frying Time/ Temperature" table.

That lard for deep-fat frying can be used and reused. I sometimes just leave it in the kettle between uses. Or I strain it through a cloth or fine sieve to remove food particles and then store it in the refrigerator. After frying strongly flavored food, like fish or onions, a few slices of potatoes put in the cold lard and then heated until well browned will absorb the flavor. Then strain the hot lard.

Fat should never be heated above 400°F. Thaw frozen foods before you fry them to avoid lowering the fat temperature. Fry pieces of similar sizes at the same time. The kettle should about half full of fat and you should add fresh fat as needed. To avoid a greasy taste, don't overload the kettle, which would cause the temperature to drop and the frying time to increase. Test the fat's temperature with the fat-frying thermometer.

Accumulation of burnt particles will cause the fat to spoil sooner than it would otherwise. Remove this accumulation by straining the fat through several thicknesses of cheesecloth. For a clearer fat, draw it off into a separate container, and after it has cooled to below 200°F, sprinkle the surface with water. The water carries down to the bottom the particles of burnt food that have been suspended throughout the fat. The clear fat can then be poured off the sludge of water and burnt particles. Or the water, sediments, and thickness of fat can be drawn off the bottom of the container if it has an outlet at its base. Test taste fat before returning it to the kettle so you're sure it isn't rancid.

Meat, fish, and chicken pieces are usually dipped in a frying batter of seasoned milk, egg, and flour and placed immediately into the hot fat. Or dip them into a seasoned water-egg or milk-egg mixture, then roll in flour, crumbs, or...
cornmeal. Foods with a moist surface (such as oysters) are dipped in crumbs, then batter, and again in crumbs. Croquette mixture should be chilled, shaped, then rolled in crumbs.

**Fritters.** These are a food dipped in batter and then fried in generous fat. You can make fritters out of just about anything—chicken, oysters, vegetables (of any kind), or fruits such as bananas, pineapples, and apples. They were very popular around the turn of the century. If you've got lot of lard, these are fun to experiment with.

Use clear oil or lard for frying, about 3 inches deep, to cook fritters. Heat the fat hot enough that a bit of batter dropped in will immediately rise to the surface and begin to brown. Don't put in too many fritters at once. Brown first slowly add 1/4 c. milk, then 1/2 T. cooking oil, and, finally, 2 well-beaten eggs. This gets puffer, but I like the plain batter best for taste.

**FRITTER BATTER** Combine 1 c. flour and 1/2 t. salt; slowly add 1/2 c. milk, then 1 T. cooking oil, and, finally, 2 well-beaten eggs.

**BAKING POWDER FRITTER BATTER** Combine 1 c. flour, 1/2 t. salt, and 1 1/2 t. baking powder. Slowly add 1/2 c. milk, then 1 T. cooking oil, and, finally, 2 well-beaten eggs. This gets puffer, but I like the plain batter best for taste.

**VEGETABLE FRITTERS** Cook, drain, and cut the vegetables into convenient-sized pieces before coating with the batter.

**APPLE FRITTERS** Peel and core tart apples and cut them into round, thin, slices. If you want to give them the gourmet treatment, marinate them briefly in a mixture of brandy, lemon juice, and sugar. Drain and dust with flour. Fry on both sides in butter, drain, and sprinkle with powdered sugar and cinnamon. Serve hot.

**BANANA FRITTERS** Peel bananas, cut in halves, and split each piece lengthwise. Sprinkle with lemon juice before coating.

**MEAT FRITTERS** Use cooked, cold meats. Parboil oysters and other shellfish.

**CORN FRITTERS** Combine leftover corn (1 c. more or less), 3 beaten eggs, 3 T. flour, seasoning, and 1 t. baking powder. No need for further batter; you've made your own. Drop by spoonfuls into the hot fat. You can substitute other leftover vegetables in this.

**LARDING MEAT** Marie Oesting of Ocean Park, WA, writes, "We used to lard meat on the farm. I called my mom (she's 88) and asked her the details. Here goes. Beef cans good, but pork can't because it's so fat. So, they would take the pork chops and also the fresh pork sausage (seasoned but not smoked) and lard them down in a 20-gal. crock. Fry the meat thoroughly, so it's dry and extremely well done. Mother said she always salted the pork chops and sausage but doesn't know whether that's really required for preservation or not. When they are thoroughly fried, layer them into the crock, covering with melted lard (not the fat they were cooked in)."

**PIECRUST** Basically, this is a mixture of flour and fat. The size of the bits of fat varies, as does the amount of water. For piecrusts, use 1 1/2 c. flour sifted with 1/2 t. salt. Use 2 forks or knives to work in 1/2 c. lard. When the fat has been worked in until it is more or less of uniform texture, add 4 or 5 T. cold water slowly until mixture becomes a stiff dough, which will hold together in one ball. Roll out and cut into the shape you need.

**Pigs' Feet**

Clean the pigs' feet. Be sure to remove the toes and dew-claws, the glandular tissue between the toes, the hair, and any dirt.

**PICKLED PIGS' FEET** Cover pigs' feet with boiling water and simmer until tender, 2 1/2–3 hours. In a large enamel pan combine 1 qt. vinegar, 6 whole cloves, 2 bay leaves, 1 stick cinnamon, 2 T. salt, 1/2 t. pepper, 1/2 c. brown sugar, and 1 onion, sliced. Simmer 1 hour. Strain liquid to remove spices. Add 2–4 c. liquid in which pigs' feet have been cooked. Pour over feet and chill 2 days, if possible. This is right for 8 pigs' feet. (You can also use pig hocks or knuckle bones to make this.)

The winter of 1946–47 we lived on a wheat ranch near Clyde Park, Montana. There I got my precious little goat, my first goat, on Christmas morning. That morning I heard a funny sound in the living room, jumped out of bed, ran in there—and there was a baby goat tied to the Christmas tree, trying to eat the tinsel. It was my beloved pet and pal from then on.

Late in January my birthday came, and I turned 8 years old. Later yet, spring finally came, the time of year when every few days we would hear the bleating baa-a-a-s as bands of sheep were hurried by up the blacktop highway a quarter mile away. The shepherders were driving them off the valley bottom, where the sheep were wintered, up into the mountains, where the snow was now melting and the grass was coming on green and beautiful.

Every time we heard that sound, Mother gave me a bag of cookies and a thermos of hot chocolate (spring was by no means warm in Montana). Then I ran down our long lane to find the shepherd who drove the flock. The herders always were happy when I came running up behind them with the cookies and cocoa. They never failed to share them with me. We'd sit inside their sheep wagon, that small summer home on wheels, or on its back steps. I'd eventually get around to asking if they had any bums.

I knew that herders of hundreds of sheep preferred not to be bothered with the ones that were orphaned and needed special feeding or that were sick or injured and unable to keep up with the flock's migration—that long walk up to summer pasture. I came home with so many bums that by spring's end, I had a flock of 7 lambs of my very own. I fed cow's milk to them in a pop bottle with a black rubber nipple pulled onto the end of it, and they all thrived. I had blind ones and lame ones, but they all knew who I was and loved me. I sure wasn't lonesome that summer. We were milking about 5 cows, so there was plenty of milk for them.

But those happy memories were followed by sad ones. In the hot August dog days of summer, a city-raised hired man who had just had his noon lunch in the house filled his tractor at our farm gas pump and then carelessly rubbed out his cigarette on the side of a tractor. As he pressed the hot butt on the place where gas had spilled time and again from the hose inlet above, the act instantly started a fire. In rapid succession, the fire burned the tractor, spread to the fuel-soaked ground in front of the pumps, and went on to
the adjacent tool and coal-storage shed. From there it blew over to ignite our house’s roof.

Because we had no phone and no car that day (Daddy and our single vehicle were away working in a far-off field), Mama sent me running down the lane as fast as I could to get help from our nearest neighbors, who lived not all that near. Mr. Steiner happened to be home, flagged down a car on the highway, told the driver to take me to town so I could spread the call for help there, and then left to help fight the fire. I ended up spending hours at Chet’s Service Station in Clyde Park with the old man who was left tending the station after everybody else had jumped into vehicles and zoomed away to our ranch. I was hoping not to be forgotten—waiting to be taken back home and wondering about my pets.

When I had left, the fire had been burning only the tractor and the ground around it. But I could see from town the big column of black smoke over our place. And I got to thinking about how my 7 bum lambs and the goat always sheltered from the noon heat in the rear of that shed, napping away the hottest hours. It worried me a lot, but I hoped somebody had thought to open the back door of the shed and let them out. Surely Mama or somebody had done that. If I had been there, I certainly would have.

I refused to believe they had all—every last one of them—been dead for a long time. I climbed up the big butte in back of our house and called them, evening after evening. I hoped that the big fire had merely frightened them off. Finally Daddy took me to the blackened rubble where the shed had been, and with his boot toe he pointed out bones in the fire debris. It was the first time creatures I’d loved so much and cared for so well had died—and all of them at once. All I had left were lifelong memories that would always be dear. But learning to let go is part of having animals, or people, that you love in your life.
Chronology of This Book

December 25, 1969.
For Christmas, my mother-in-law gave my husband Mike and me a subscription to Organic Gardening, along with some back issues.

February 12, 1970.
Rebecca Neoma Emery was born.

Summer 1970.
"Old Fashioned Recipe Book" idea came to me.

September 1970.
Wrote the table of contents. (Believed I could finish the book in 2 months.) Placed an ad to appear in the November and December 1970 issues of Organic Gardening.

November and December 1970.
Received about 250 orders. Wrote all the people saying I'd send the book when done and promised them it would be only a couple more months.

March 1971.
First "issue" mailed to the "subscribers." It consisted of chapters on herbs, definitions and measures, and home industries except a still-to-be-written section on candles.

September 1, 1971.
Luke Carl Emery was born.

December 17, 1971.
Second "issue" mailed after I raised funds to do so by advertising to get more subscribers. About 200 more people ordered. The second issue consisted of beverages and half of a chapter on meats. Then I was sick for a while. We traded our 3 acres and a house as a down payment on 115 acres and a house.

September–December 1971.
Printed and mailed the third issue: chapters on oddments and food preservation and half of a chapter on dairying. Also sent larger binding rings because the book was turning out to be bigger than I'd expected. Then stopped writing.

Sara Ann Emery was born. Sold goats on neighbor's request. Bought Nelly the cow.

After a long break I prayed, felt directed, and went back to work on the book.

Dolly became very sick. Sara was also sick.

February 18, 1974.
The book was finally finished. Dolly was better, Sara was well, and I was happy! But I still had to manage printing the book.

March 1, 1974.
The first edition (the one that came out in issues) and the second edition (the first whole book) were printed and put in the mail to my customers, thanks to Diann, Darlene, and the good collators.

By the late February, Diann had been mimeographing for weeks. Then there was a collating bee, organized by a librarian at the Moscow Public Library. I didn't know her, but she had heard of me. About 6 ladies came to the bee, which was in an empty apartment in the old folks' home that Viola Johns (Diann's mother) ran; I'd never met most of them before.

Diann introduced me: "This is our author." Everybody looked at me hard for a minute to see what an author looks like. I said, "Hello" and "Thanks for coming to help," and that was pretty much the end of it. They kept walking around that table collating, probably because they hadn't anticipated such huge piles of paper and they wanted to get home for dinner. We were doing 200 copies of what I called the fourth issue of the first edition, and then we put together 200 more of the "second edition," which would have the improvement of being an all-at-the-same-time book, to say nothing of the text additions and improvements I'd made in the earlier chapters.

My job was hauling boxes full of envelopes holding the fourth issue in the back of my pickup from the work area to the post office. When I got back for the next load and walked in the door, they nodded and kept going around the table. I saw they had already finished about 8 of the whole books. They had no way of knowing what was going on inside me. I had sort of thought I'd be the person to put the first whole book together. But no matter. I elbowed my way into the line that was going around and around the table and picked up the first of the 12 chapters. I couldn't say a word. I couldn't smile. The emotion in me was so intense and huge. I took a step, picked up the second chapter from its pile and laid it on top, and so on around the table until the last chapter, "Definitions and Measures," and then the back cover. And now I held it in my hands—a completed copy of the Old Fashioned Recipe Book. The first one I had ever held in my hands, a miracle!

I clutched it to me, turned, and walked back out the door alone, so full of feeling I thought I'd burst. Just up the hall I found an empty laundry room, went in, and closed the door behind me. There I knelt down, crying with gratitude, and talked to God and thanked Him.

There was more work to be done, hauling boxes to the post office. So then I went back to the collating place, and things just took up again as if nothing spectacular had happened. Only my heart knew better.

April 10, 1974.
Third edition finished. (As soon as I finished the first two, I thought of more things I wanted to include!)
I tried another classified ad in Organic Gardening—2 months at $200/month, and this time only one order. I tried selling to libraries and bookstores, working from mail-order lists, but they wouldn't buy at a high enough price to allow me a profit. There had to be another way to reach potential buyers with no middleperson. In the meantime, Viola rented her apartment. We moved the bookmarking to Diann's home, but it outgrew her living room. We had to find another place to do it. We rented an empty restaurant on Main Street in Kendrick for $75 a month. We collated on the abandoned counters and, with great care, settled in the precious new $1,200 mimeograph machine which, by the grace of God, had been allowed to us on time payments of $45 a month. Diann and Darlene started keeping regular office hours at the store, even though I owed each of them anywhere from $300 to $700 depending on which day or month you looked at, and the whole town was telling them they were fools. We painted huge, brave red-and-white signs on the outside of our new home advertising the Recipe Book, and did a little off-the-street business. I desperately needed to sell more books, and directly to readers, but how?

Then some college boys from the University of Idaho at Moscow visited me and urged me to take part in a craft fair they were organizing for Moscow's Main Street. I never turn anybody down, and as usual we were in a situation where if I didn't find $250 somewhere, we wouldn't be able to pay our paper bill and would have to shut down forever on the following Monday. So I took a folding table and all the children, and we set up shop there in the sunshine. I passed out hundreds of brochures and sold $300 worth of books.
May 26, 1974.

An index was added, and then we called it the fifth edition.

But the Idaho fairs just weren't big enough to support the kind of volume I needed to pay Diann and Darlene, the rent for the Livingroom Mimeographer, and the payment on the machine. Once again, it looked like the end. Then we heard of a 3-day craft fair 500 miles away, near the Pacific coast, in Bellevue, Washington (a suburb of Seattle). It was to take place on Thursday through Saturday. I said to Diann and Darlene, "I'll try it just this one more time. I'll go clear to Seattle. If I don't make it this time, I'll submit to the inevitable—I'll give it all up." That week's mail-order money was just enough to pay gas one way to Seattle. As usual, I took all 5 children (ranging in age from 1 to 10) plus blankets, a bag of groceries, and so many books I was afraid my poor old car wouldn't make it over the long, steep Alpowa grade over the Blue Mountains just west of Lewiston, Idaho. But it did. That night the children and I slept squeezed like sardines in the car, parked behind a shopping center. A policeman saw us, came over, and got very uptight about the whole idea of it, though he didn't arrest me.

The next day I found out I had the date wrong. The fair existed, but it didn't start until Friday. So I had Thursday to kill. I decided to try to get on TV. At a shopping center, I hunted for a phone. A nice secretary in a real estate office let me use theirs. I looked in the Yellow Pages for TV stations and called the "Seattle Today" TV show people to ask if I could get on that weekend. Meanwhile, my kids were kind of getting into things. At that moment, the bosses at the real estate office came in. The "Seattle Today" people told me on the phone they had an unexpected cancellation that day, and I should be there in 1 hour! The real estate people told me to please take my children and leave, and I did.

We headed for the KING studio; we'd never been there before. A split second we found it in time. The children couldn't find all their shoes, so I made them stay in the car in the parking lot, looked after by the nice parking attendant. I rushed into the studio, and there you had a study in contrasts. The hostess of the live show was in an evening gown, her makeup expertly done, her hairdo lovely. I was in work clothes and tennis shoes, with bags under my eyes.

The show was a smashing success!

Afterward, we headed back to the shopping center. The children had supper and I didn't, because we were getting low on food. The next day, bright and early, we set up for our fair. We sold $300 worth of books that Friday, plus I met some people who became my good friends before the summer was over—people who make quickie trips to Mexico and buy up goods there to sell at fairs here, and people who spend long winter months working in their basement craft shops (or some such places) painstakingly creating beautiful things and then, all summer long, weekend after weekend, take those things to one craft fair after another trying to sell them for enough money to get through another winter.

It's a very special way to make a living, and there's a warm camaraderie among the folks who live that way. They took me in as a sister and began to teach me the things I so badly needed to know: when the big, good shows were, what you had to do to get into them; the fine points of just where to put your table to catch the best crowd flow; how to hawk your wares; and how to get along with the management. They told me that, although the fair there in Bellevue seemed so good, there was going to be an even better one Saturday and Sunday up in the Fremont district of Seattle. They were all going there, some leaving a friend to tend their tables in Bellevue. I went along, and Fremont was a whole new experience for me.

I thought I was arriving in Fremont plenty early Saturday morning at 6 am, but wow was I late! There were hundreds of craftspeople already there—600, according to the brochure I saw later. Mobile TV cameras and reporters were already out getting stories for the morning news. All the good spots were already taken. I had to settle for a spot out on the edge of the fair. Nonetheless, I did $500 worth of business that day. The kids and I slept in the car again that night, and nobody minded. The next day, business was even better. I ran out of books, so then I took orders. So many would-be customers were crowding in wanting my book that I felt just overwhelmed. But then people appeared from nowhere to help me. They passed out brochures, took orders, and helped with the children. They begged and insisted until finally I went off and bought myself a 7-Up in a little nearby restaurant while they continued selling books back at my table.

I started to feel like a small sort of celebrity. People would come up and say, "Everybody's talking about your book." I walked back with my drink and saw them gathered here and there around one of my brochures, eagerly talking. That night the children and I slept in a motel, and we all had showers and we woke up brightly in our comfort. We bought a big bag of groceries—including luxuries like avocados and fruit juice—to celebrate. After the little ones were put to bed, my oldest daughter, Dolly, and I sat up and totaled the money we were taking home. We could scarcely believe our eyes—it was over $1,000. I remembered how once I had numbly apologized to Darlene because I still had no money to pay her, and I knew how much she needed it. She responded with words I'll never forget: "Oh, Carla, I just wish I had some money of my own so I could lend it to you." But now I could give Diann and Darlene all their much-deserved and long-awaited wages, and catch up on the other bills too!

After that I went to Pacific coast fairs every weekend. There was always one—or more—going on in that heavily populated region. The biggest problem was getting over Alpowa while heavily laden with outward-bound books. Once when I was driving the family truck, I caught on fire. Flames and black smoke were coming up through the crack all around the outside edge of the hood, and I could see flames in the floorboard insulation around the brake and gas pedals. I stopped as soon as I could get over to the side of the road. I got out and raised the hood—and there was my engine burning merrily away.

I didn't know what to do next. I was no mechanic. I depended on Mike for things like that. Just then a Greyhound bus saw us and stopped right in front of us; the driver got out and ran toward us, holding a fire extinguisher. It shot a white powder all over the engine and put out the fire. We thanked him, and he drove off in his big bus.

Then we realized the fire had gotten going again, down in the floorboard insulation. We had no liquid, we tried to put dirt on it, but that was no good because the dirt couldn't get down to the places where the fire was smoldering. A farmer stopped, said he'd get us some water, and drove away. We kept moving the dirt, trying to hold down the flames until he could get back. He came back and...
soaked the thing out good and final. The truck engine was ruined. We ended up going over Alpowa in the wee small hours in the car, pulling a U-Haul trailer full of books.

That was the time we were going to do 5 fairs on the coast in the same weekend, so it was an extra heavy load of books. Darlene and her 5 kids in her car came along with me and mine and some extra young people to do the selling. Once we got to Seattle, I had to lead Darlene to the fair site in Tacoma where she was going to sell books. We happened to get on the freeway at rush hour. I had already been introduced to freeways and had learned how different they were from our 2-lane country roads at home, and I’d forgotten what a shock they could be. I found out later that Darlene drove down that freeway behind me crying all the way. But she hung in there behind me, and we got there okay.

From May 15 until December, I was home only 1 weekend. That was in August, when I was just too sick and exhausted to go out. That week Mike and I talked it over, and we decided to submit to the necessities. I had been leaving home just in time to get to the fair, generally on the late side because I had so much I wanted to do at home: time with Mike, working in the garden, all the canning and freezing, catching up with my milk cow. Mike tried to keep the cow going while I was gone, but she and Mike just couldn’t get along. Then a pile of mail was always waiting for me, and there were people to call and decisions to make and, of course, I always had all 5 children with me whether I was at home or on the road. So I generally didn’t get any sleep the night going to the fair, because I’d leave late and drive all night. And I generally didn’t get any sleep the night coming home, because I was always so anxious to be with Mike again that I’d just drive straight home without sleeping.

But after I got sick, we talked it over and decided I wouldn’t try to come home every week, as I had been doing. Instead I would go out for a few weeks at a time—or more. I did that, and my cow went dry, and the stock cows got into the garden about 3 different times and ate everything to the ground (everything that they didn’t trample, that is). We had to get rid of some animals because no one could stay home with them, and some of my young fruit trees died for lack of water.

Sometimes I got home and felt like bawling because it all looked yellow with dryness, deserted, and rundown, as if nobody lived there. Here I was out telling everybody about the great country life and raising your own food, and there wasn’t anything in my own cellar but the green beans, turnips, and peas I’d put up during the first part of the summer. But then I’d think about how people had come up to me and told me about the first garden they’d ever had, or the new home in the country and what a joy it was to them, and how my book had helped them. Then I’d feel so good, and I’d tell myself I’d have a milk cow and a garden again for sure the next year.

First trip to California. We got a press agent, Julaine, and some TV and radio interviews—and a red-and-white van to sleep in when away from home.

December 31, 1974.
I publicly announced my plans to build a School of Country Living after Mike and I made the down payment on a beautiful 386-acre ranch nearby. I wrote the first schedule of classes and planned to open it in May.

January 1, 1975.
The children and I left for 4½ months on the road, circling the entire United States, doing radio and TV and newspaper interviews, telling people about the book and the School of Country Living.

Summer 1975.
First session of the School of Country Living.

Fall 1975.
Went back on the road until Christmas to sell books and recover expenses: another national tour with children in van.

January 10, 1976.
Sold rights to Bantam for $115,000 cash advance. With that money I planned to do a School of Country Living again.

Summer 1976.
Second school session. Flash flood washed away much of the school. I gave up.

Fall 1976.
Went back on road (pregnant) to pay off the debts—once more the big circle all around the United States.

Jacob Michael Emery was born.

August–December 1977.
Toured to promote the Bantam edition (the seventh). Travelled with the 6 children and, for TV demos, a nanny, a milk goat, a turkey, a goose, and some rabbits. I was becoming a popular and sometimes paid performer on TV talk shows (Johnny Carson, Mike Douglas) with my comedic country-girl routines. Actually, I didn’t so much deliberately set out to be funny as that’s just how it happened. I was generally late and had no time to get nervous. And I’d have my baby in my arms. (I always had my baby.)

February 1978.
Mike Douglas’s TV show flew me down to Los Angeles. Here’s how it happened:
My fourth nationwide tour was the longest and most successful yet. Back home from that tour, I was still busy and still responsible for the Living Room Mimeographer’s production, even though Bantam was now producing a commercial edition. I was still willing to do interviews and farm-girl comedy routines. The staff of Mike Douglas’s show kept calling me up. I’d done several shows for them before, but I wasn’t planning to tour again for a while. So they asked me to fly to Los Angeles and perform especially for them again. I agreed. After all, it’s quite up and upward, right? And they would pay me $250 an hour and foot the bill for my plane fare, hotel room, and chauffeur and limousine while I was in town.

I certainly was climbing the ladder of success. It was flattering to realize I was good at something—TV comedy. That I could stand before all those cameras and be relaxed, interesting, and funny—even when I wasn’t selling the Recipe Book. Fame, fortune, success . . . and back home we always needed more money. My husband had long since quit his town job. The girls at the Mimeographer . . . the kids . . . all expecting me to make money . . . more money. Like a monkey on my back . . . all those expectations and needs. Getting money was becoming the big thing in my life. Couldn’t be poor.

The Mike Douglas staff was adamant about one thing: I couldn’t bring my children, not even my baby. That hurt. I’d never left my children behind before. I didn’t want to be separated from my baby, not even for 36 hours. But they wouldn’t accommodate me on that point. “That’s how it’s done,” I was told. I figured I’d better bend to fit them: $250 a minute. So I agreed. I left and flew in a jet to Los Angeles. There were 2 big reasons why I had previously driven around the United States, again and again, in a van—above and beyond the fact that I wanted to get my books to people in towns of all sizes. First, I couldn’t bear the idea of being separated from my children and needed a way to bring them along. And second, I am the ultimate white-knuckled flyer. But here I was, without even my baby, umpty-thousand feet above terra firma in a vibrating jumbo jet. I pulled
a magazine out of my handbag. It had a feature article about me, written by a local journalist, a woman who'd followed the Recipe Book saga from the very beginning. I read it, and it's a wonder I didn't punch a hole in the aluminum floor of the airplane and fall through to Earth—all of a sudden I felt so heavy. The gist of her message was that Carla had gone Hollywood, turned hypocrite, apostatized her own dream of country peace and quiet. There was more truth to her angle than I was comfortable with. Lord, what a gift the press can give us, to see ourselves as others see us.

The plane landed. My chauffeur met me at the gate, and drove me in a long black car to an elegant hotel with a doorman. This uniformed character stood outside under a long, narrow, sideless awning that seemed determinedly pretentious. I was conveyed to my suite and left alone. Not just a room—a suite! Room after empty, elegant Holly­

staff. I can't remember what I did or what I said. I do re­

mance on this live TV show, the way mine sometimes had.

And a spacious, luxurious, outer sitting room. For the

knuckled flying back to Idaho. When I got home I told

stood for, and wanted them to believe in and become.

A sleepless night in that cavernous bed; next came white-

moral danger. I felt that, above all, I had to save my chil­

happened with mine. How might it affect them if they

something shocking to get people's attention and keep them

money. And that's show business, right?

attention equals success, fame, the throngs of reporters? None present. For the throngs of fans? Mine wouldn't look for me in such a place. I was alone. It was deadly, depressingly lonely. I wasn't used to ever being alone. I didn't feel right. I wanted my baby.

Time to do my show. Chauffeur and limo again . . . ex­

citement . . . being fused over by the show's staff. The

make-up room to make me beautiful. The Green Room

where I'd await my turn in the spotlight. I was brought out

to wait just offstage early enough to overhear the last few

minutes of the episode preceding mine. Mike Douglas was

talking with 2 major female stars in the movie-theatrical

sky. He asked one, "If you could live your life all over again and have it be any way you wanted, what would you do dif­

ferently?"

She answered, "I'd be a man."

He asked the other, "If you could live your life all over

again, what would you do differently?"

She answered, "I wouldn't have any children."

Her words chilled me to the soul. Like everyone else, I

knew that actress through media reports. She had 5 chil­

dren. I wondered if they were at home watching her perfor­

mance game. The conversation probably was sketched out

ahead of time with the show's staff. Or perhaps her children were bored with Mom as a celebrity and no longer bothered watching, as had later happened with mine. How might it affect them if they heard, or heard of, her words? What a chance she was tak­

ing.

Oh, I understood well enough. It was all the perfor­

mance game. The conversation probably was sketched out

ahead of time with the show's staff. Or the staff may have

trusted those 2 professional women to do as required to put

on an exciting show. Those words were the smashing finale, something shocking to get people's attention and keep them

from switching channels. Attention equals success, fame, money. And that's show business, right?

But the chill in me wouldn't be explained away. It was

my turn to go on, and I had to suddenly be upbeat and

witty and whatever else it was that I can be that people can

love and that was worth $250 a minute to the Mike Douglas

staff. I can't remember what I did or what I said. I do re­

member that I was fighting a feeling that I had just seen the

devil under the tinsel, the gaping maw of corruption and

moral danger. I felt that, above all, I had to save my chil­

dren from thinking that this was what I wanted, believed in,

stood for, and wanted them to believe in and become.

Then it was time for the limo back to the celeb hotel and

a sleepless night in that cavernous bed; next came white-

knuckled flying back to Idaho. When I got home I told

Mike it was all over for me, that what I wanted more than

anything else in the world was to be a good mother and a

good wife and to practice what I preached. I pulled the plug

on the whole career thing and let it run down the drain. I

folded the Living Room Mimeographer and let Bantam

make all the books. Eventually sales slowed to a miniscule

trickle because I did no more book-selling interviews or

tours. Mike Douglas's staff soon quit calling after I stead­

fastly refused to come back. I heard from a Hollywood

screenwriter interested in turning my book-writing and

selling adventures into a movie. I said no.

Instead, Mike and I agreed to work on an exciting new

personal project together: a seventh baby.

April 18, 1979.

Esther Marie Emery was born.

September 1985.

Mike left. Five days later, I began writing again—a diary

this time.

I was divorced with custody of the children.

January 1986.

I began work on an eighth edition of this book and con­tin­

ued working on the diary.

Last night I had to do some heavy deciding about the new

edition of this old book that has been almost like a com­

bination of life's work and diary to me over the years. In 3

weeks Mike is having a beautiful church wedding with a

couple hundred invited guests. It's my job to make sure our

7 children are there, looking appropriately well-dressed and

in suitably positive moods for a festive occasion.

The old-timers I've so revered got married, had big fami­

lies, and stayed together until death did them part, maybe

whether they were happy or not. I was born into a differ­

t era. I'm certainly not the only woman—or man—this ever

happened to. Each of us then has to find our own way of

adapting to the transition, of making a positive restructur­

ing of our lives by discovering a new vision to live for and

strive toward. Because you gotta have a dream.

What do I do about new editions of this book? After our

divorce, the first time I was editing the book and came to a

passage in which I spoke of my love for Mike, I deleted it.

And then another such. But the next day I realized I had to

put them back and not do that any more. My marriage to

Mike is history and, in more than one sense, this book is

history. You don't change history. That's dishonest. What I

am free to change, or try to change, is the future. When

Mike asked for his freedom, by default I also received the

gift of mine.

What do I do about the future—of this book and of my

life? Well, I keep on living for the positive, convinced that it

is always better to heal than to wound, to love than to hate,

to make peace than to make war. And yet I am now perhaps

more aware of subtle and necessary distinctions in the prac­

tice of those ideals. I have a clean conscience about my

marriage: over those many years, I gave it the best I could. I

put them back and not do that any more. My marriage to

Mike to make peace than to make war. And yet I am now perhaps

more aware of subtle and necessary distinctions in the prac­

tice of those ideals. I have a clean conscience about my

marriage: over those many years, I gave it the best I could. I

put them back and not do that any more. My marriage to

Mike to make peace than to make war. And yet I am now perhaps

more aware of subtle and necessary distinctions in the prac­

tice of those ideals. I have a clean conscience about my

marriage: over those many years, I gave it the best I could. I

put them back and not do that any more. My marriage to

Mike to make peace than to make war. And yet I am now perhaps

more aware of subtle and necessary distinctions in the prac­

tice of those ideals. I have a clean conscience about my

marriage: over those many years, I gave it the best I could. I

put them back and not do that any more. My marriage to

Mike to make peace than to make war. And yet I am now perhaps

more aware of subtle and necessary distinctions in the prac­

}
and my mothering gets lighter all the time as my children grow older. I'm going to write! I want to write more books, print more books, sell more books, to travel and do fairs and say "Hello" to America again across my book-laden selling table. It's going to be a marvelous adventure. I'll love and be loved by so many unique, wonderful people—male and female, young and old—as I share my writing with them. It's a completely different thing from loving and marrying one man—I'm going to love and be loved by masses of people: these readers whom I want to serve. I'll give myself to my readers with the same fire, loyalty, and dedication with which I once gave myself to a single person—Mike. Yes, now I want to belong to you, as I once thought of myself as belonging to him.

With this transition I'm going to be freer to think than I was before. I want to daringly reconsider both the given and the forbidden, to live a challenging life of the mind, searching for both open and obscure facts, for I'm a lover of data. The coming years may well be the best, happiest ones of all my life. I'm truly looking forward to them.

Bantam lets the Recipe Book go out of print. All rights return to me. The book is now "out of print." But people still write and want copies.

I begin selling a copier-produced eighth edition by mail.

October 1989.
Three different universities have asked to be designated as the repository for my papers, manuscripts, etc. I choose the University of Idaho. I take them all my old newspaper-clipping and photo scrapbooks, copies of the old editions, etc. We create a separate, closed depository, its contents to be made public only with my consent or upon my death. I begin doing research for another book, related to the diary materials.

Chad Haight of Sasquatch Books, a Seattle publisher, wrote and asked me for permission to publish a new commercial edition of the book. I agreed. From then until now I've been going to their office every Wednesday morning at 9:30am to turn in another chunk of revised or new text. I'm working with Lane Morgan, a fine author in her own right, who looks over the manuscript for problems; Anne DePue, editor-in-chief, who organizes the process; and Pam Milberg, intern, who helps sort material and keep the order of it sensible. Coming up, yet to be met, are a noble copy editor and a talented artist. I've never before produced the book with so much skillful help, and I think you're going to be impressed by the miracles that team effort can achieve! This new edition is definitely becoming the book of my dreams, the one I was trying to write from the very first day—after all these years.
VARIOUS EDITIONS DESCRIBED
If you’re looking at an older copy of this book and wonder which edition it is, here are some hints:

First Edition. By subscription only, arriving in 4 consecutive shipments, mimeographed on Fibertint; 875 copies finished about March 1, 1974.

Fifth Edition. Index added; 13,000 mimeo copies started May 26, 1974.

Sixth–Seventh Edition. Half new paging and half old paging; rewrites added. Index dropped due to confused paging; 4,000 mimeo copies started November 22, 1976.

Seventh Edition. All chapters fully revised and also now illustrated by Cindy Davis; 25,000 (?) mimeo copies started March 12, 1977.

The first 7 editions (before the Bantam edition) were 3-hole-punched and usually were bound with a bent length of plastic-coated copper wire in pretty colors or were Velobound (with a soft or hard cover).

Eighth Edition. Chapters called “Poultry,” “Meats,” “Definitions and Measures,” “Home Industries,” “Vegetables,” “Sweets,” and “Oddments” were revised. Starting March 1990, about 3,000 copies were made by copy machine. Gradually upgraded through various printings; another 1,000 done byoffset. Again 3-hole-punched, bound with 2-inch metal binder rings.

Ninth Edition. The one you’re reading. Title and much of “Definitions and Measures” chapter dropped to make room for new information. Indexed and fully illustrated; el suprema version so far. And massaged by Sasquatch’s editors to make my writing follow (most of) the rules that in the past I’ve been famous (infamous?) for spurning. No more world records for typos. Oh, well.

Updated Ninth Edition. More than 1,500 mail-order sources, checked and updated, with the addition of web-sites and e-mail addresses.

WORLD RECORDS THIS BOOK MAY HAVE SET
1. More typographical errors, run-on sentences, general horrors of composition, handwritten inserts, and inky fingerprints in the first edition and others than any other book on record. (I wrote the Guinness Book of World Records people and they said the number of typos did represent a world record, “but you have to count them.” Never had time.)
2. Weirdest page numbers . . . Where else have you seen “½” pages? Or “26c”? That’s because with each edition, I kept adding more material and didn’t want to mess up the existing page numbering.
3. First author in history to have had 3 babies in the same 4½ years during which she gave intellectual birth to a 5-lb. book.
4. Biggest mimeographed book in general circulation: 936 pages at its largest. Then I discovered elite type! Then I discovered pica condensed. (The book stayed at 900-some pages; I just kept squeezing in more words.)
5. Most self-published copies sold. Even if it’s not a record, it’s a lot. And most copies of a mimeographed book sold: 88,000 (I’m sure that’s a record). (That figure doesn’t include the sales of the Bantam and Sasquatch editions.)
6. Most words (now over a million) by 1 person in 1 book.
7. Longest time spent writing 1 book (32 years).
YOUR ACHIEVEMENT CHECKLIST

1. Grind a handful of grain coarsely for cereal. _____ Grind finely for flour. _____
2. Mix, knead, raise, punch down, raise, and bake a loaf of bread. ______
3. Put on a bee suit and open a hive. ______
4. Make yogurt. ______
5. Start with cream and take it through every step until it has become a salted ball of butter and a glass of buttermilk. ______
6. Make cottage cheese. ______
7. Make a hard cheese. ______
8. Milk a goat. ______
9. Put a cow in the stanchion and milk her. ______
10. Feed the poultry and gather eggs. ______
11. Clean out a rabbit hut. ______
12. Plan and cook a meal in which the food is 100 percent home-grown. Breakfast _____ Lunch _____ Dinner _____
13. Raise, catch, kill, scald, pick, singe, cut up, and cook a chicken. ______
14. Dry a batch of fruit or vegetables in a food dryer. ______
15. Take out the ashes. _____ Build a fire in a wood stove. ______ Adjust the dampers. ______
16. Freeze a batch of a fruit or vegetable. ______
17. Make a batch of sourdough starter. _____ Cook a meal of sourdough pancakes using that starter. ______
18. Make homemade noodles. ______ Crackers ______
19. Dry and save seeds from an annual. ______ A biennial ______
20. Separate milk. _____ Take apart, wash, dry, and reassemble the separator. ______
21. Make a batch of homemade ice cream using a crank freezer. ______
22. Harness a team of horses (or oxen). _____ Hitch them up to an implement or wagon. _____ Till a field with them. _____
23. Build housing for animals. _____ Repair or build a fence. ______
24. Correctly identify 10 different herbs from sprigs laid out on a table. ______
25. Make a pot of herb tea from herbs you have grown and harvested. ______

A FINAL EXAM FOR YOU

1. What is the basic bread recipe?
2. How can you start one beehive off another?
3. How do you make cottage cheese?
4. If you had no livestock feed store to buy commercial feeds at, what would you grow, and approximately how much of it or what proportions would you feed your goat every day in winter? Rabbit? Cow? Chicken? Pig?
5. What's a “potato onion”? How do you grow garlic? What prevents motion sickness?
6. What can you use to make a variety of home-grown, caffeine-free coffee?
7. If you have no electricity, gas, or other "modern" energy source, how can you preserve meat? Fruits? Root vegetables? Squash and pumpkins?
8. What do you use for potato seed? How do you plant potatoes?
9. What is the correct weight at which to butcher a broiler chicken? A rabbit? A pig?
10. State the advantages and disadvantages of keeping a goat or a cow for home dairy use.
11. What aspect of soap making is very dangerous, and how can you minimize that risk?
12. What can whole wheat be used for?
13. How do you make a homemade cheese press?
14. What is the best way to house an expectant doe rabbit?
15. How would you grow and harvest a grass grain without using any fossil fuel in the process?
